Methods: This was a retrospective chart review study. From July to August 2016, 93 US oncologists/hematologists provided data abstracted from medical charts of their CLL patients who initiated a first-line CLL treatment between January 2010 and December 2014. The study collected patient demographics, clinical characteristics, response to first-line therapy, and the number of all-cause hospitalizations between first-line therapy initiation and end of the data follow-up (*i.e.*, patient's date of death, end of care, or data collection date, whichever occurred first). Patients were selected based on their best response to first-line therapy (*i.e.*, CR, partial remission [PR], stable disease [SD] and progressive disease [PD]) as defined by the physician according to iwCLL 2008 criteria. The targeted number of patients in each category was *a priori* determined based on rates of response observed in clinical trials. The incidence of all-cause hospitalization was compared between patients who achieved CR and those who did not (including patients with PR, SD or PD) using univariate and multivariate generalized linear models with a Poisson distribution. As patients had different follow-up, incidence rates were reported per-patient-per-month (PPPM). Multivariate regression models were adjusted for age, gender, selected comorbid conditions, time from CLL diagnosis to first-line initiation, and Eastern Cooperative Oncology Group (ECOG) status.

Table 1.

Table 1. Comparison of hospitalization between CR and non-CR cohorts

	CR IR PPPM	Non-CR IR PPPM	*Unadjusted IRR (95% CI)*	*Adjusted IRR (95% CI)*
All-cause hospitalization	0.006	0.021	3.30 (1.69-8.21)	2.44 (1.13-6.42)

** The number of hospitalizations was not available for a total of 29 patients (17 CR and 12 non-CR patients).*

Results: Patient-level data was collected for 179 patients who achieved CR and 151 patients who did not achieve CR (120 patients with PR, 25 with SD, and 6 with PD). Average time from CLL diagnosis to first-line initiation was 8.4 months for patients who achieved CR and 13.3 months for those who did not. The majority of patients were male (65%), the average age was 63 years, and 80% of patients had an ECOG of O or 1 at first-line therapy initiation. The medi-

an follow-up after first-line therapy initiation was 30 months. Over that period, patients who did not achieve CR had statistically significantly higher incidence of all-cause hospitalization compared to patients who achieved CR (0.021 *vs* 0.006 PPPM; unadjusted incidence rate ratio [IRR]=3.30, p<0.05). After adjusting for potential cofounders, the incidence of all-cause hospitalization was 2.4 times higher for patients who did not achieve CR compared to those who did (IRR=2.44, p<0.05).
Summary/Conclusions: Results from this study showed that achieving CR to first-line therapy (vs. not achieving CR) is associated with reduced frequency of all-cause hospitalizations. This suggests that, in addition to the clinical benefit associated with CR achievement, treatment strategies in CLL that improve CR may help reducing the economic burden of CLL management for both patients and payers.

E1036

RITUXIMAB (R) USED AS A SINGLE AGENT FOR AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA) IN TREATMENT NAÏVE CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS INDUCES ALSO SIGNIFICANT DISEASE RESPONSE WITHOUT TOXICITY

S. Sachanas[1,*], G. Pangalis[2], M. Moschogiannis[1], X. Yiakoumis[1], P. Tsirkinidis[1], E. Koulieris[1], C. Kalpadakis[3], E. Poppis[4], T. Vassilakopoulos[5], M. Angelopoulou[5]
[1]Hematologic, Athens Medical Center, Psychiko Branch, [2]Hematologic, Athens Medical Center,Phychikon Branch, Athens, [3]Hematologic, University Hospital, University of Crete, Heraklion, [4]Blood Transfusion, Athens Medical Center, Psychiko Branch, [5]Hematologic, Laikon General Hospital, University of Athens, Athens, Greece

Background: There are very few effective treatment options for steroid refractory AIHA of CLL or for CLL patients(pts) that are unable to receive corticosteroids. R has been noted to be active in certain autoimmune hematologic disorders while experience with single-agent R in untreated CLL pts is very limited.
Aims: To report our experience concerning the use of R as a treatment of AIHA occurring during the clinical course of treatment naïve CLL pts by analyzing concomitantly its efficacy and safety as a single agent in CLL therapy
Methods: 15 pts diagnosed with CLL who received R due to AIHA were included in this study. Staging was performed at diagnosis (Binet system). Pts were placed on R at the standard dose I.V of 375mg/m^2 once weekly for 6 consecutive weeks because of contraindication of corticosteroids administration
Results: Pts' median age was 60 y(range, 42-83 y), (8 out of 15, males), 10 having disease stage A and 5 B. Two were presented with splenomegaly and 1 with B-symptoms. 12 pts (83%) had leukemic lymphocyte counts of more than 50x10^9/L. Median time from diagnosis, the AIHA diagnosis and to 1st R infusion was 59 mos. All 15 pts completed the 6-week course of R and were assessable for response. The median WBC and the median absolute lymphocyte count(ALC) before R administration and after the end of 6-week course are shown in the Table. Resolution of the AIHA effect was achieved in all pts whereas in 4 there was a persistence of positive DAT without evidence of active hemolysis. After the end of 6 weekly R infusions 13 out of 15 pts (86%) showed also disease response. 12 pts experienced PR (80%) and 1 CR (6%). All pts with advanced disease also responded entering PR. Resolution of splenomegaly was documented in both splenomegalic pts. After a median follow up of 84, 5 mos from CLL diagnosis, 14 pts are alive, 9 maintain their disease response while 5 were in need of therapy due to CLL progression, after a median time of 10 mos from the last R infusion. Among them 4 were placed on FCR (2CR, 2PR) and 1 on R-Bendamustine(PR). Median PFS has not reached. All pts received the entire first dose on day 1 of treatment. There was only a grade 3 infusion related reaction in a patient with WBC>400x10^9/L without need for hospitalization. None of the pts experienced severe tumor lysis syndrome, pulmonary insufficiency, myelosuppression or opportunistic infections.

Table 1.

Table: Median WBC and median ALC

	Before R	After 6 R
mWBC × 10^5/L (range)	63,7(6,9–521,4)	7,6(4,0-38,3)
mALC × 10^5/L (range)	58,0(2,4-480,0)	3,2(0,8-30,2)

Summary/Conclusions: A) R is an effective agent for AIHA treatment with concomitant significant activity against CLL and therefore could be the standard of care for CLL pts with AIHA, especially for the cohort of pts with comorbidities. B) We confirm previous data that: 1) single-agent R induces significant responses in treatment naïve CLL pts 2) R is well tolerated and its administration is not associated with myelosuppression or immunosuppression 3) R as a single agent could be an excellent first-line treatment option for pts who are very elderly or who have a poor performance status

E1037

ATTAINMENT OF COMPLETE REMISSION IS SIGNIFICANTLY ASSOCIATED WITH LONGER SURVIVAL OUTCOMES IN RELAPSED/REFRACTORY (R/R) CLL: A META-ANALYSIS

V.U. Ektare[1,*], C.P. Fox[2], R.S. Taylor[3], T.I. Inocencio[1], G.E. Pena[4], J.C. Maher[4], S.J. Snedecor[1]
[1]Pharmerit International, Bethesda, United States, [2]Nottingham University Hospitals, Clinical Hematology, Nottingham, [3]University of Exeter Medical School, Exeter, United Kingdom, [4]AbbVie, Inc., North Chicago, United States

Background: Chronic lymphocytic leukemia (CLL) is an incurable neoplasm of B lymphocytes, associated with a heterogeneous clinical course. Complete response (CR) with/without minimal residual disease in first-line chemoimmunotherapy has been associated with more favorable progression-free survival (PFS) and overall survival (OS). However, patients (pts) with R/R CLL and/or those with TP53 abnormalities (ie, 17p deletion and/or TP53 mutation) are less likely to achieve deep responses and experience poorer outcomes. Therefore, less is known about the relationship between CR and survival outcomes in R/R CLL pts.
Aims: To quantify this association, we generated meta-analytic estimates of PFS and OS reported in clinical trials using the proportion of study patients with CR as a predictor variable.
Methods: We performed a systematic literature review of PubMed/EMBASE up to Nov 2014 and congress abstracts 2012–2014. Randomized controlled trials and observational studies evaluating any treatment in R/R CLL pts were eligible for inclusion. Data were extracted from publications as median survival, the proportions of pts surviving at specific follow-up times, or individual event or censoring times from reported Kaplan-Meier (KM) curves, along with the proportion of pts with CR. Data were synthesized to estimate overall OS and PFS including population-level CR as a covariate using a Weibull proportional hazards model within a Bayesian meta-analysis framework.
Results: 74 published studies of treatment outcomes in R/R CLL pts were identified from the peer-reviewed literature and congress abstracts. 56 of these studies reported the proportion of CRs together with either OS or PFS outcomes and were included in the analysis. Individual pt data were extracted from KM curves of 29 studies generating 5176 individual pt OS and PFS data points in addition to 54 study-level data points including 3638 pts. There were no clinically meaningful differences in study or pt characteristics among the included studies that were not also associated with CR, our variable of interest. The hazard ratio (HR; and 95% credible interval, the Bayesian analog to confidence intervals) of survival for each 10% increase in CR among a study population was estimated to be 0.64 (0.60, 0.68). Estimated median OS for hypothetical populations with 0% CR, 25% CR, or 50% CR were 20.4 mo, 44.7 mo, and 61.9 mo. Corresponding median PFS estimates were 10.0 mo, 21.9 mo, and 30.3 mo. (Figure 1).

Figure. Weibull meta-analysis estimates of OS (A) and PFS (B) with median survival times for a population with 0% CR, 25% CR and 50% CR

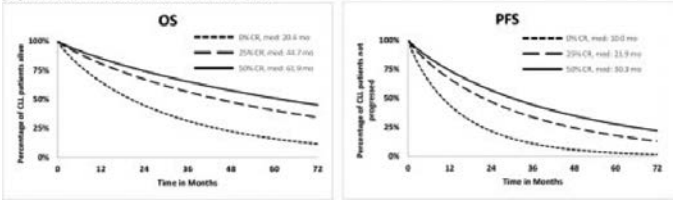

Figure 1.

Summary/Conclusions: The attainment of CR is significantly associated with longer OS and PFS outcomes in R/R CLL at the study level. Moreover this can be expressed linearly, with each 10% increase in CR rate corresponding to a 36% reduction in the risk of progression or death. To our knowledge, this is the first meta-analysis to quantify the relationship between CR and survival outcomes in R/R CLL pts. It must be noted that these results reflect the study (*population)* level CR *versus* survival association and therefore do not necessarily represent the expected survival gain associated with an *individual* achieving CR. Further, CR is less likely to be achieved in pts with TP53 abnormalities, a factor not explicitly considered in our analysis. These results synthesize data from 56 clinical trials and strongly support the importance of achieving CR to improve long-term outcomes in R/R CLL pts. In particular, given the negative association between CR and TP53 abnormalities, treatments focused on improving the likelihood of CR in these hard-to-treat pts are likely to confer the greatest impact on survival outcomes.

E1038

APLICATION OF THE CLL-IPI AND THE MDACC PRGNOSTIC INDEXES IN A LOCAL COHORT OF CLL PATIENTS

I. González-Gascón Y Marín[1,*], M. Poza[1], M. Hernández-Sánchez[2], A.E. Rodriguez-Vicente[2], M.S. Infante[1], C.C. Muñoz Novas[1], C. Heras[1], M.A. Foncillas[1], J.M. Hernández-Rivas[2], J.Á. Hernández[1]
[1]Hospital Universitario Infanta Leonor, MADRID, [2]IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: New prognostic scores have been developed in order to better discriminate the clinical course of CLL patients, along with Rai and Binet clinical staging systems. These scores, such as that proposed by the MDACC group, and recently the CLL-IPI combine clinical and biological variables with prognostic value.
Aims: In this study we investigated the validity and reproducibility of these scores in a local cohort of patients with CLL.
Methods: We made a retrospective analysis including 650 unselected CLL patients newly diagnosed and previously untreated from a single institution. The final analysis has been limited to the 486 cases with complete data to apply the MDACC score, and to the 258 cases with complete data to apply the CLL-IPI score.
Results: Median age was 67 years old (25-90). With a median follow-up time of 46 months, 394 patients were alive, and 187 had received any treatment for CLL at the moment of the analysis. Median overall survival (OS) of the whole series was 173 months (127-220), and median time to first treatment (TTFT) 106 months (82-130). The MDACC score was applied to 486 cases giving 0 to 9 points to each case according to: age, b2-microglobulin levels, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups. As shown in the Table, stratification of patients using the MDACC score allowed the prediction of prognosis for both TTFT (P=0.000) and OS (P=0.000). 162 patients were classified as low risk, 302 as intermediate risk, and 21 as high risk. Due to missing data, the CLL-IPI score could only by applied to 258 patients giving 0 to 10 points to each case according to *17p* deletion, *IGHV* mutational status, β2-microglobulin, clinical stage, and age. As shown in the table, 126 patients were classified as low risk, 79 as intermediate risk, 46 as high risk, and 7 as very high risk. We also found significant differences in terms of OS (P=0.000) and TTFT (P=0.000) using this score.

Table 1.

	Number of patients	Overall survival (months)	P	Time to first treatment (months)	P
MDACC score			0.000		0.000
Low risk (1-3)	162	238 (IC 95%, 146-330)		133 (IC 95%, 110-155)	
Intermediate risk (4-6)	302	141 (IC 95%, 131-151)		81 (IC 95%, 46-115)	
High risk (≥7)	21	63 (IC 95%, 52-74)		2 (IC95%, 0-4)	
CLL-IPI score			0.000		0.000
Low risk (0-1)	126	238 (IC 95%, 147-330)		Not reached	
Intermediate risk (2-3)	79	144 (IC 95%, 128-162)		53 (IC 95%, 34-71)	
High risk (4-6)	46	74 (IC 95%, 57-91)		7 (IC 95%, 5-10)	
Very high risk (7-10)	7	32 (IC 95%, 21-42)		9 (IC 95%, 0-21)	

Summary/Conclusions: In this study we confirm that both scoring systems are able to discriminate patients in different prognosis subgroups. Both scores are also easily applicable in clinical practice. The new CLL-IPI score is able to distinguish subgroups of patients with worse prognosis including new factors (17p deletion and mutational status of IGHV).

CHRONIC LYMPHOCYTIC LEUKEMIA: PROGNOSTIC VALUE OF CLINICAL STAGES AND CLASSICAL PROGNOSTIC PARAMETERS DEPENDING ON TREATMENT MODALITY

T. Baumann[1,*], J. Delgado[1], P. Mozas[1], V. Ortíz-Maldonado[1], R. Santacruz[2], M. Rozman[3], M. Aymerich[3], N. Villamor[3], D. Costa[3], A. Carrió[3], E. Montserrat[1]
[1]Hematology Department, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS, University of Barcelona, Barcelona, Spain, [2]Hematology Department, Hospital de Clinicas, Asunción, Paraguay, [3]Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: Prognostication is a key component in the management of patients with chronic lymphocytic leukemia (CLL). Prognostic factors however may change as a result of the introduction of more effective therapies.
Aims: To investigate whether the prognostic value of classical parameters has changed over time.
Methods: Retrospective single-center study of prognostic factors and outcome in patients with CLL diagnosed before (n=454) and after (n=903) 1995 when purine analogs and subsequently chemoimmunotherapy (CIT) were introduced in CLL treatment at the Hospital Clínic, Barcelona.
Results: The median follow-up up was 8.3 years (0.1-33.0) for the overall series and 24.9 years (21.9-33.0) and 7.8 years (0.1-21.3) for patients diagnosed before and after 1995, respectively. Patients diagnosed before 1995 were older (p<0.001), had more advanced clinical stage (p<0.001), higher ALC (p<0.001), shorter LDT (p<0.001), and more often anemia (p=0.028), thrombocytopenia (p<0.001) and increased serum LDH levels (p=0.019) than those diagnosed thereafter. There were no differences in B2-microglobulin (B2M) levels and ZAP70 or CD38 expression. Mutated *IGHV* was more frequently detected in patients diagnosed before 1995 (75% *vs* 55%; p<0.001). The proportion of patients receiving treatment did not differ between groups [42% (38-47%) *vs* 46% (42-49%) at 6 years; p=0.08]. The type of therapy given to patients diagnosed before and after 1995 was: alkylating agents (91% *vs* 34%), purine analogs (4% *vs* 27%), CIT (0% *vs* 31%), other (5% *vs* 8%) (p<0.001). The response rate was lower in patients diagnosed before 1995 (57% with 9% CR *vs* 67% with 36% CR; p<0.001) and overall survival (OS) was shorter (median; 8.0 *vs* 10.1 years; p<0.001). The median OS in patients diagnosed before and after 1995 broken down by clinical stage was: stage A: 10.1 *vs* 10.9 years (p=0.1); stage B: 4.5 *vs* 9.2 years (p<0.001); stage C: 3.8 *vs* 3.8 years (p=0.2). In both groups of patients univariate analyses demonstrated a correlation between OS and clinical stage (both p<0.001), age >70 years (both p<0.001), B2M (both p<0.001), short lymphocyte doubling time (LDT) (both p<0.001), unmutated *IGHV* (both p<0.001), and ZAP70 (p=0.015 and p<0.001). High-risk FISH correlated with OS in patients diagnosed after 1995 (p<0.001). In patients diagnosed before 1995, the number of subjects with available FISH was too small for a meaningful analysis. In multivariate analysis (age >70 years, advanced clinical stage short LDT increased B2M, diagnosis before 1995) only age (HR 2.7 (95% CI: 2.1-3.4), p<0.001), LDT (HR 2.5 (1.9-3.2), p<0.001) and B2M (HR 2.8 (2.2-3.6), p<0.001) showed independent prognostic significance for OS. *IGHV* mutational status, ZAP70 and high-risk FISH cytogenetics correlated with OS but these variables were not included in multivariate analyses because of the many patients with missing information.
Summary/Conclusions: Survival of patients with CLL in intermediate-risk (stage B) disease has dramatically improved over the last years. In contrast, the outcome of patients with either low (stage A) or high (stage C) stage has not been significantly modified, indicating the need for more effective therapies in these patients. Importantly, the prognostic significance of classical prognostic variables has not changed after the introduction of more effective therapies. Finally, similar studies are warranted in patients treated with novel agents.

E1040

AN OBSERVATIONAL STUDY EVALUATING THE USE OF BENDAMUSTINE AS FIRST-LINE TREATMENT FOR CHRONIC LYMPHOCYTIC LEUKEMIA IN RUSSIA

E. Stadnik[1,*], V. Mladov[2], K. Kanhai[3], A. Zaritskey[1]
[1]Almazov Federal North-West Medical Research Centre, Saint Petersburg, [2]Clinical Trial Support, Smolensk, Russian Federation, [3]Astellas Pharma Europe, Middle East and Africa, Chertsey, United Kingdom

Background: Bendamustine has gained footing as a component of first-line therapy for chronic lymphocytic leukemia (CLL) due to its efficacy and favorable toxicity/tolerability profile for most patient types. There is a dearth of data on the effectiveness of bendamustine as first-line therapy in the Russian CLL patient population, which is needed to support drug cost reimbursement processes.
Aims: Evaluate effectiveness of first-line therapy with bendamustine for CLL in the Russian Federation.
Methods: This was a prospective, multicenter, observational study (NCT02110394) in adults (>18 yr) diagnosed with CLL who were receiving, or were scheduled to receive, first-line therapy with bendamustine plus rituximab. Patients who had prior CLL treatment (eg, chemotherapy, radiation) or had contraindications to bendamustine were excluded. Each subject was required to have 2 to 8 study visits, where Visits 2–6 reflected treatment cycles; total number of treatment cycles for each patient was determined by the study investigator. Interim and final evaluations were performed after 3 and 6 treatment cycles, respectively. Primary endpoints were overall response rate (ORR, patients achieving complete remission [CR] plus those achieving partial remission [PR]). Secondary endpoints were time to therapeutic failure, time to progression, progression-free survival (PFS), relapse or death after CR or PR, quality-of-life (EQ-5D questionnaire), and frequency of adverse drug reactions (ADRs).
Results: Of the 196 patients who enrolled between June 2012 and August 2015, 191 were included in the Safety Population (patients who received ≥1 dose of study drug) and 149 were included in the Full Analysis Set (FAS; patients in the Safety Population who had ≥1 response evaluation). Most patients in the FAS were male (59.7%); mean age was 61.5±8.9 yr. Overall, 35.6% of patients were ≥65 yr old and 80.5% had ≥1 comorbidity such as decreased renal function. The ORR was 83.2%; CR and PR rates were 59.7% and 23.5%, respectively. Generally, response rates were slightly higher than those reported in the Phase 3 pivotal trial (Knauf *et al. J Clin Oncol*. 2009). Eradication of minimal residual disease was achieved in 23 of the 84 evaluable

patients (27.4%). Overall, 80.3% of FAS patients did not experience therapeutic failure and 85.9% did not experience disease progression during the 2-year observation period. By the end of the study, median PFS had not been reached; 2-year PFS rate was estimated as 85.9%. Improvements from baseline were observed after 6 cycles of treatment across all EQ-5D domains. No relapses or deaths occurred in the FAS; however, 2 subjects in the Safety Population experienced fatal serious ADRs (myocardial infarction [n=1]; acute pneumonia, infections and toxic shock, and atrial fibrillation [n=1]). In concurrence with the Phase 3 trial results, hematologic disorders (19.9%; anemia, neutropenia, thrombocytopenia), most of which were Grade ≤2 in severity, were the most common ADRs (Safety Population; **Table 1**).

Table 1. Hematologic ADRs by CTCAE Grade.

Hematologic ADR	Grade ≤2 (%)	Grade ≥3 (%)
Anemia	49.2	0.9
Neutropenia	21.7	17.5
Thrombocytopenia	5.3	0.5

Summary/Conclusions: First-line therapy with bendamustine plus rituximab was well tolerated in this Russian CLL population, including elderly patients and patients with renal dysfunction or other comorbidities. Additionally, combination therapy resulted in high rates of treatment response in the CLL. These data confirm the value of bendamustine as a first-line agent for CLL in routine clinical practice in Russia.

Chronic myeloid leukemia - Biology

MUTAGENESIS OF BCR-ABL1 IS REQUIRED FOR RESISTANCE DEVELOPMENT IN DE NOVO CHRONIC MYELOID LEUKEMIA KCL-22 CELLS BUT NOT IN RELAPSED KCL-22 CELLS EXPRESSING BCR-ABL1 INDEPENDENT RESISTANCE

N. Curik[1,2], V. Polivkova[1,3], T. Kalina[4], V. Kanderova[4], J. Linhartova[1], F. Savvulidi[2], O. Toman[1], K. Srutova[1], S. Ransdorfova[1], J. Brezinova[1], H. Klamova[1,5], K. Machova Polakova[1,5,*]

[1]Institute of Hematology and Blood Transfusion, [2]Institute of Pathological Physiology, First Medical faculty, Charles university, [3]Faculty of Science, Charles University, [4]Department of Paediatric Haematology and Oncology, Univ. hospital Motol, [5]Institute of Clinical and Experimental Hematology of the 1st Medicine Faculty, Charles University and Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: *BCR-ABL1* kinase domain (KD) mutations are an important mechanism of resistance of chronic myeloid leukemia (CML) patients developing during the tyrosine kinase inhibitors (TKI) treatment. However, mechanisms underlying KD mutation acquisition in TKI-resistant CML cells are not yet well understood.

Aims: We studied an acquisition of mutations in the KD after an exposure of *de novo* and relapsed (grown in optimal growing medium for 24 months) KCL-22 cells to imatinib (IM). In addition, we examined kinetics of mutated subclones in established IM-resistant KCL-22R culture after dose-reduction of IM. We also studied changes in the expression profile of KCL-22 cultures early after exposure to IM.

Methods: The occurrence and kinetics of expansion of *BCR-ABL1* mutant subclones were studied using next-generation deep sequencing in KCL-22 cells treated with 0.4 μM IM and in established IM-resistant KCL-22R cells at 4 μM IM. In other set of experiments, KCL-22R cells were sorted according to the CD38 expression to explore whether CD38 is associated with the acquisition of *BCR-ABL1* mutations as suggested by Wang *et al*. (2014). A protein array was used allowing analysis of 576 proteins per sample. DNA damage pathway-RT Profiler PCR arrays were applied for gene expression analysis.

Results: No *BCR-ABL1* KD mutations were detected in *de novo* untreated KCL-22 cells, however T315I and E255K appeared after the exposure of the cells to 0.4 μM IM. PCR array revealed increased expression of SUMO 1 ligase and ERCC2 involved in the nucleotide excision repair pathway. Notably, we also found a significant decrease of G2/M-checkpoint protein GADD45A whose deficiency is associated with mutagenesis (Hollander *et al*., 2001). During the first culture period, T315I slowly emerged whereas E255K was not detectable. Later, E255K-bearing cells also became detectable and increased over time. A similar time-dependent expansion of mutant-bearing sub-clones was seen in the KCL-22R cells growing at 4 μM IM. Interestingly, a mutant-clone switch from T315I to E255K in KCL-22R was accelerated after IM reduction from 4 μM to 1 or 2 μM. Moreover, the emerging of E255K sub-clone was accompanied by rapid decrease of CD38 expression in KCL-22R cells. Profiling of transitional KCL-22R culture, carrying both T315I and E255K sub-clones, revealed that T315I transcripts were expressed only in the CD38+ subpopulation, while E255K was detected only in CD38- cells. Unlike to *de novo* KCL-22 cells, *BCR-ABL1* mutations were repeatedly not detected in relapsed KCL-22 cells up to follow-up of 60 days after the cells exposure to 0.4 μM IM. Neither *BCR-ABL1* upregulation nor gene amplification was detected in these cells. We identified considerably upregulated (D7, DTX3, ETV6, GLUL, HCLS1, HIF1α, IGF1R, MAP2K7, MYH11, TP53) or downregulated (BAD, BID, MCL2 NOTCH3, PDKPK1) proteins early, 4 weeks after the exposure to IM. Increased expressions of HIF1α and IGF1R proteins are known to ensure proliferation, while decreased expressions of pro-apoptotic proteins BAD and BID enhance survival of CML cells in the presence of TKIs.

Summary/Conclusions: Our observation suggests the ability of KCL-22 cells to survive and proliferate early after the exposure to IM. *BCR-ABL1* mutations development seems to be related to a mutagenesis of imatinib on *de novo* KCL-22 cells, but not on relapsed KCL-22 cells that activated signaling pathways ensuring their survival and growing in the presence of tyrosine kinases inhibitor.

Supported by the project no. 00023736 and AZV 15-31540A of MZCR and ERDF OPPK CZ.2.16/3.1.00/28007.

Città della salute e della Scienza di Torino, Torino, [7]Hematology Unit, Dept. of Medical Sciences, Bone Marrow Transplant Center, R. Binaghi Hospital, Cagliari, Italy

Background: Diagnosis of Chronic Myeloid Leukemia (CML) implies documenting in bone marrow (BM) or in peripheral blood (PB) Philadelphia (Ph) chromosome by cytogenetics, molecular BCR-ABL1 fusion by FISH or BCR-ABL1 rearrangement by RT-PCR. In clinical practice, at the earliest, 24-72 hrs are needed to confirm CML by any of these assays. Lately, characterization of CML leukemia stem cells (LSCs) from BM samples of CML patients (pts) showed a specific co-expression of dipeptidylpeptidaseIV (CD26) within the $CD34^+/CD38^-/Lin^-$ stem cell fraction and CD26 appeared a robust biomarker for identifying CML LSCs within the normal BM compartment. We recently demonstrated that $CD34^+/CD38^-/CD26^+$ LSCs can be easily identified by flow-cytometry also in PB during treatment with tyrosine kinase inhibitors.
Aims: We investigated accuracy and specificity of flow cytometry PB $CD34^+/CD38^-/CD26^+$ LSCs identification as a new tool for the diagnosis of CML.
Methods: Pts with clinical suspicion of CML entered the study after written informed consent and all were evaluated for $CD26^+$LSCs, cytogenetics, FISH and/or BCR-ABL1 RT-PCR analysis. $CD34^+/CD38^-/CD26^+$ population was investigated in PB and when possible simultaneously in BM samples using a flow-cytometry 4-color staining procedure. $2.0x10^6$leucocytes were incubated with BD Pharmigen CD45V500 (c.2D1), CD34FITC (c.581), CD38APC (c.HIT2), CD26 (c.M-A261) and negative controls. Acquisition and analysis of at least $1.0x10^6$ $CD45^+$ cells were done by FACSCanto II with DIVA 8 software (BD, Biosciences). $CD26^+$ cells were identified by sequential gate. $CD45^+$ and $CD34^+$ gates were performed on viable cells identified by FSC/SSC light properties and $CD34^+/CD38^-$ population was gated applying a narrow gate excluding all $CD38^+$ cells (Fig.1).
Results: PB samples from 107 pts with myeloproliferative features were evaluated for $CD26^+$LSCs. Leucocytes median value was $52x10^9$/L (range 5-$408x10^9$/L). In 83/107 (77.5%) pts we showed $CD34^+/CD38^-/CD26^+$ LSCs in PB and in 83/83 (100%) the diagnosis of CML was confirmed by cytogenetics, FISH and RT-PCR analysis. Median value of circulating PB CD26/µL was 14 (range 0,27-698) and a positive correlation with leukocyte count ($p<0.01$) was found. In 53/107 (49,5%) pts analysis was performed contextually in BM samples. All $CD26^+$ PB-BM matched pairs (49/53) showed superimposable results in terms of absolute number of $CD26^+$LSCs/µL (19,18 and 18,73 respectively) while the percentage of $CD26^+$ cells within the $CD34^+/CD38^-$ fraction appeared lower in BM than in PB samples (median 28,18 and 37,33; range 0,87-77,14 and 5,59-99,57 respectively). In 24/107 (22.5%) PB samples and in 4/53 BM samples $CD26^+$ LSCs were not detected and none of these samples was found Ph or BCR-ABL1 positive. Pts with CD26 neg PB/BM samples were subsequently diagnosed as Idiopathic Myelofibrosis (12 pts), Myelodysplastic/Myeloproliferative disorders (7 pts) benign neutrophilia (5 pts). Of note, we additionally studied 4 PB+BM samples of 4 Ph+ acute lymphoblastic leukemia and all scored negative for $CD26^+$LSCs.

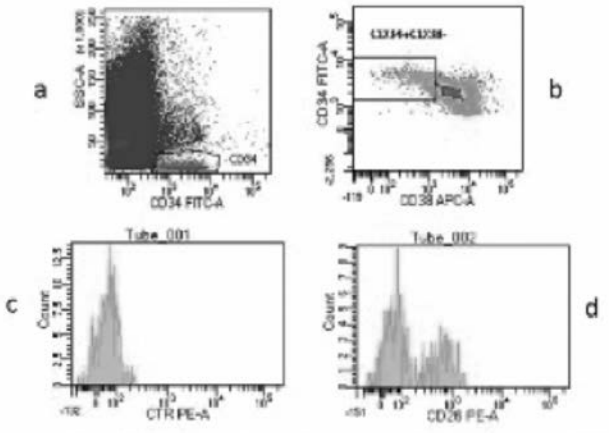

Fig 1 PB CD26⁺ LSCs evaluation in a representative CML patient. CD34 gating on viable cells identified by FSC/SSC light properties (a) $CD34^+CD38^-$ population gated applying a quite narrow gate that excluded also a proportion of CD38 dim cells (b). Negative control (c) and CD26 expression on $CD34^+CD38^-$ population (d). In the case here depicted the percentage of $CD26^+$ cells within the $CD34^+CD38^-$ fraction was 43,7% corresponding to 17,4/µL of circulating $CD26^+$LSCs

Figure 1.

Summary/Conclusions: Flow-cytometry evaluation of PB $CD34^+/CD38^-/CD26^+$LSCs is a feasible, very rapid (about 3 hrs from sample handling to results) and highly specific alternative/complementary diagnostic tool for CML. To validate these data in a larger cohort of patients we are developing a pre-titrated lyophilized antibody mixture (lyotube, BD Biosciences) to maximize sensitivity and to optimize standardization and working time, with the further aim to monitor stem cells minimal residual disease in CML patients.

Emanuele, University of Catania, Catania, [8]Hematology with Transplant, University of Bari, Bari, [9]Hematology Unit, USL8, Arezzo, [10]Clinic of Hematology, University of Genova, Genova, [11]Hematology, Sapienza University, Roma, [12]Hematology, University "Federico II", Napoli, Italy

Background: Evidences of increased cardiovascular (CV) events, mostly atherothrombotic, in Chronic Myeloid Leukemia (CML) patients (pts) treated with some Tyrosine Kinase inhibitors (TKIs) prompted physicians to carefully evaluate CV risk factors (CVRFs) in the choice of TKI. However, the pathogenesis behind CV events during TKIs is still largely unknown and even pts without overt CVRFs incur in CV events. We retrospectively showed that an induced "inflammatory status" during nilotinib treatment, together with genetic pro-atherothrombotic predisposition, may partly explain the increased incidence of CV (Bocchia, Oncotarget 2016). These data provided the rationale to start a multicentric "Prospective study of T**KI** induced pro-**A**therothR**O**mbotic status in CML. KIARO study" (Grant support: AIRC-ITT) including Chronic Phase CML pts treated with any first line approved TKI in which clinical, genetic and biochemical pro-atherothrombotic profiles were evaluated at diagnosis and during treatment.
Aims: This prospective study aims to confirm the possible role of genetic predisposition and behavior of specific pro/anti-inflammatory biochemical parameters in the atherosclerotic pathogenesis during TKIs treatment.
Methods: Enrolled pts were prospectively evaluated for: presence of traditional CVRFs, atherothrombotic episodes, presence of Single Nucleotide Polymorphisms (SNPs) associated to CV risk (Cardiokit) and plasma levels of several pro and anti-inflammatory cytokines. In this first interim analysis we focused on levels of LDL, oxidated-LDL (oxLDL), TNFα, IL-6 and IL-10 and the presence of SNPs of LDL-R (rs1122608), LOX-1 (rs3736235), and IL-10 (rs1800896) genes.
Results: 12 Italian Hematology Units participated to the study and up to date 95 CML patients were enrolled. We here report data from the first 43 patients on TKI treatment for at least 12 months (15 nilotinib, 14 imatinib and 14 dasatinib,. No CV events were recorded to date. At diagnosis, levels of LDL (143.5±13.2), ox-LDL (237.4±99.5), TNFα (3.91±2.51), IL-6 (1.96±0.99) and IL-10 (0.34±0.15) were evaluated for the whole cohort and according to the TKI treatment. No statistically significant differences were found in the expression of these variables between the 3 groups of treatment ($p>0.096$). Considering the genotype frequency, we confirmed in the whole cohort a correlation between basal levels of LDL, oxLDL and IL10 with the presence/absence of the detrimental G/G allele of LDL-R (H.R. 2.11, $p<0.01$), LOX-1 (H.R. 2.86, $p<0.01$) and IL10 (H.R. 1.85, $p<0.05$) polymorphisms. During TKIs treatment we observed increased levels of LDL ($p<0.05$) and oxLDL ($p<0.05$) only in the nilotinib cohort at 3 and 12 months of treatment, regardless of the concomitant use of CV medications. No differences in TNFα and IL6 levels during the first 12 month of treatment were detected in the 3cohort ($p<0.079$). Interestingly, IL-10 levels were significantly higher at 3 and 12 months of treatment in the imatinib and dasatinib cohort ($p<0.01$) respect to nilotinib ($p=0.094$).
Summary/Conclusions: This interim analysis, although still very preliminary, suggests that in nilotinb patients the high levels of LDL and oxLDL in combination with low levels of IL10, could induce a persistent pro-inflammatory/oxidative status potentially favoring atherothrombotic events. Additional biochemical and genetic data as well as prolonged clinical observation are needed to confirm this hypothesis. Patients enrolment and monitoring is ongoing.

TRANSCRIBED ULTRACONSERVED NONCODING RNAS (T-UCRS) IN CHRONIC MYELOID LEUKEMIA: EXPRESSION PROFILES ASSOCIATED WITH MOLECULAR RESPONSE TO THERAPY WITH TYROSINE KINASE INHIBITORS

P. Rodrigues Santos[1,2,3,*], P. Abranches[1,2,4], P. Couceiro[2,3], J.R. Simplício[2,3], J.S. Almeida[2,3], V. Alves[1,3], L. Růžičková[5], P. Freitas-Tavares[5], M. Santos-Rosa[1,3]

[1]Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, [2]Laboratório de Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, [3]Centro de Investigação em Meio Ambiente, Genética e Oncobiologia (CIMAGO), Faculdade de Medicina da Universidade de Coimbra, [4]Departamento de Ciências da Vida, Faculdade de Ciências e Tecnologia da Universidade de Coimbra, [5]Serviço de Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Transcribed ultraconserved regions (T-UCR) are a novel class of long noncoding RNAs. Many classes of noncoding RNAs have been implicated in human tumorigenesis. In addition to the different expression profiles of T-UCRs that could be used to distinguish human leukemias and carcinomas, they have also been reported to have direct interactions with miRNA with an important regulatory effect in disease development such as chronic myeloid leukemia (CML).
Aims: In this study, we aimed at the correlation of T-UCR and miRNA:T-UCR pairs in CML, according to tyrosine kinase inhibitor (TKI) therapy, clinical risk scores and molecular response.
Methods: We analysed peripheral blood samples from 45 CML patients and 15 healthy controls. Two panels of 481 T-UCR and 752 miRNA probes were used for RT-qPCR analysis. Differential expression was evaluated using the Mann-Whitney test followed by Benjamini-Hochberg multiple testing correction.
Results: CML samples presented significantly different expression of uc.164 ($p<0.01$), uc.118 ($p<0.01$), uc.125 ($p<0.01$), uc.391 ($p<0.01$), uc.153 ($p<0.01$), uc.141 ($p<0.01$), uc.143 ($p<0.05$) and uc.145 ($p<0.05$), when compared to healthy controls. This latter T-UCR (uc.145) was associated with development and immune regulation pathways. We analysed Sokal, Hasford and EUTOS risk scores and found uc.236 ($p<0.0001$), uc.39 ($p<0.05$) and uc.7 ($p<0.05$) to be associated with EUTOS low risk. Concerning therapy, dasatinib was correlated with uc.187 ($p<0.005$). For imatinib doses, uc.4 ($p<0.05$) and uc.3 ($p<0.05$) inversely correlated with 400 and 800mg daily, respectively. Molecular response in CML samples presented a signature including uc.187 ($p<0.001$), uc.107 ($p<0.05$), uc.409 ($p<0.05$), uc.198 ($p<0.05$), uc.309 ($p<0.05$), uc.102 ($p<0.05$), uc.294 ($p<0.05$) and uc.361 ($p<0.05$). Major molecular response was identified by the altered expression of uc.198 ($p<0.05$), uc.215 ($p<0.05$) and uc.210 ($p<0.05$). The negative regulation of T-UCRs by miRNAs, involving T-UCR:miRNA interaction, was associated with upregulated (miR-720, miR-886-3p, miR-1274a, miR-101 and miR-129) and downregulated (miR-489 and miR-1973) microRNAs.
Summary/Conclusions: In the present study, we identified T-UCRs signatures and T-UCR:miRNA pairs associated with CML, risk scores, TKI therapy and molecular response. The expanded knowledge of RNA biology in general, together with the recent interest in the multitude of newly discovered elements such as T-UCRs, could help to improve CML therapy.

MAINTENANCE OF LEUKAEMOGENIC POTENTIAL OF BCR/ABL+ CELLS REQUIRES PAK2 BUT NOT PAK1

A. Hoelbl-Kovacic[1,*], A. Berger[1], L. Edlinger[1], I. Menzl[1], G. Hoermann[2], E. Grundschober[1], Z. Bago-Horvath[3], V. Sexl[1]
[1]Institute of Pharmacology and Toxicology, Veterinary University of Vienna, [2]Department of Laboratory Medicine, [3]Clinical Institute of Pathology, Medical University of Vienna, Vienna, Austria

Background: p21-activated kinases (PAKs) are key nodes in oncogenic signalling pathways that control growth, survival, and motility of cancer cells. Their activity is increased in many human cancers and the increase is associated with a poor prognosis. To date, PAK deregulation has mainly been studied in solid tumours, where PAK1 and PAK4 are the main isoforms deregulated.
Aims: We aimed at identifying deregulations of PAKs in haematopoietic tumors and the potential contribution of individual PAKs to tumorigenesis.
Methods: We used a combination of *in silico* analysis of publicly available data of haematological patients, shRNA-mediated knockdown and *in vitro* transformation assays. In parallel, we analysed the tumorigenic potential of leukemic cells *in vivo* after knockdown of individual PAKs.
Results: We show that PAK1 and PAK2 are frequently deregulated in haematopoietic tumors, particularly in BCR/ABL$^+$ leukemia. In suspension, BCR/ABL$^+$ leukaemic (KU812) cells deficient for PAK1 and PAK2 undergo apoptosis, while the loss of either protein is well tolerated. When leukaemic cells are challenged to grow towards an extracellular matrix, the loss of PAK2 alone abrogates cell growth. PAK2-deficient cells fail to form colonies in growth-factor free methylcellulose and do not induce lymphomas *in vivo*.
Summary/Conclusions: PAK2 is the critical isoform in a BCR/ABL-driven disease. This finding suggests that the PAK2 isoform represents a promising target for the treatment of haematological diseases.

MIRNA PROFILING OF CIRCULATING EXTRACELLULAR VESICLES IN CML PATIENTS WITH MUSCULOSKELETAL PAIN ASSOCIATED WITH DISCONTINUATION OF TYROSINE KINASE INHIBITORS

K. Ohyashiki[1,*], M. Asano[1], T. Umezu[2], S. Katagiri[1], C. Kobayashi[2], T. Tauchi[1], M. Gotoh[1], K. Ando[1], S. Okabe[1], J. Ohyashiki[2]
[1]Department of Hematology, [2]Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, Japan

Background: Clinical trials of TKI discontinuation are still ongoing, approximately 60% of CML patients who achieved a deep molecular response for more than 2 years maintained a major molecular response after discontinuation of imatinib. However, the long-term prognosis and/or adverse events after TKI cessation remain unclear. Recent reports showed that transient musculoskeletal pain without consistent biochemical abnormalities occurs in approximately 30% of CML patients after stopping imatinib.
Aims: Recent evidences suggest that extracellular vesicles (EVs) that contain genetic element such as DNA, RNA, and miRNA, are important mediators of intercellular communication. We therefore studied molecular study to ascertain the possible correlation between musculoskeletal pain and EV-miRNA expression.
Methods: We investigated circulating EV-miRNAs in five CML patients who did not experience musculoskeletal events and five patients with musculoskeletal pain after stopping TKIs, as well as three healthy individuals. Peripheral blood was obtained approximately 3 months after successful TKI cessation in CML patients. Exosomes were extracted by using Total Exosome Isolation Reagent (Invitrogen, Carlsbad, CA, USA) and EV-miRNA profiling was performed with a TaqMan Low-Density Array (Thermo Fisher Scientific, Carlsbad, CA, USA), as reported previously. The relative expression level of each gene was calculated by using the comparative thresholds cycle (Ct) method. Synthetic spike control (ath-miR-159; Hokkaido System Science, Hokkaido, Japan) was used as an invariant control for EV-miRNA. This study was approved by the institutional review board of Tokyo Medical University (no. 930 approved 24 June 2008 and no. 3052 approved 9 June 2015).
Results: Three-way analysis of variance (ANOVA) performed for healthy controls and CML patients with and without musculoskeletal pain revealed EV-miR-140-3p to be the most significant value (P=0.00778). A t-test analysis using R software identified 10 differentially expressed EV-miRNAs for CML patients with and without musculoskeletal pain: seven miRNAs were upregulated (miR-107, miR-145, miR-140-3p, miR-539, miR-495, miR-299-5p, miR-425) and three were downregulated (miR-122, miR-218, miR-523) in CML patients with musculoskeletal pain. The up-regulated EV-miR-140-3p in all CML patients decreased after release of musculoskeletal pain.
Summary/Conclusions: CML patients with increased EV-miR-140-3p achieved levels similar to those of healthy controls after relief from musculoskeletal pain. It has been reported that there is an association between musculoskeletal pain and inflammatory indicators in some CML patients who stopped TKIs; however, we did not find any positive association. Although the number of CML patients in this study is too small to draw definite conclusions, further research should investigate whether upregulation of EV-miR-140-3p expression in peripheral blood is correlated with musculoskeletal events in CML patients after TKI cessation.

E1047

SOLUBLE AND MEMBRANE-BOUND RECEPTOR–LIGAND IMMUNE CHECKPOINTS AND CHRONIC MYELOID LEUKEMIA: CORRELATIONS WITH MOLECULAR RESPONSE AND TYROSINE KINASE INHIBITOR THERAPY

P. Rodrigues-Santos[1,2,3,*], J.S. Almeida[2,3], P. Couceiro[2,3], V. Alves[1,3], J.R. Simplício[2], L. Růžičková[4], P. Freitas-Tavares[4], M. Santos-Rosa[1,3]
[1]Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, [2]Laboratório de Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, [3]Centro de Investigação em Meio Ambiente, Genética e Oncobiologia (CIMAGO), Faculdade de Medicina da Universidade de Coimbra, [4]Serviço de Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Blockade of immune checkpoints seems to unleash the potential of the antitumor immune response in a fashion that is transforming human cancer therapeutics. Soluble and membrane-bound receptor–ligand immune checkpoints are the most druggable forms using agonist antibodies (for co-stimulatory pathways) or antagonist antibodies (for inhibitory pathways). Although its implications in immune response during chronic myeloid leukemia are obvious, literature regarding chronic myeloid leukemia (CML) and immune checkpoints is scarce.
Aims: This study aimed at the analysis of lymphocyte subsets expression and plasmatic levels of immune checkpoint inhibitors during tyrosine kinase inhibitor (TKI) therapy in CML and its correlation with molecular response.
Methods: Peripheral blood samples from chronic phase CML patients (n=55), divided according to molecular response to imatinib, dasatinib, nilotinib, bosutinib, ponatinib and Interferon-alpha 2b (IFN-α 2b) therapy, were included in this study. Multi-parametric flow cytometry was used for the analysis of the

expression of several immune checkpoint inhibitors (BTLA, GITR, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD137/4-1BB) by different T, B NK, monocyte and dendritic cell subsets. A 14-plex panel including BTLA, GITR, HVEM, IDO, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD28, CD80, CD137 (4-1BB), CD27, and CD152 (CTLA-4) was analyzed by xMAP technology (Luminex®).
Results: Expression of CD137 by several lymphocyte subsets and PD-1 by regulatory T cells (Tregs) and natural killer (NK) cells were found significantly altered in CML patients under TKI therapy. These associations were observed for the cell population frequency expressing the receptor, and also for density of these molecules. Increased plasmatic levels of BTLA, HVEM, PD-1, PD-L1, and CD137 were associated with good molecular response to therapy. PD-1, PD-L1, TIM-3 and CD137 were found increased in patients that achieved MR4.5.
Summary/Conclusions: Some immune checkpoint inhibitors seem to be affected by TKI therapy in CML and their cell expression and plasmatic levels correlates to molecular response. Similar observations were described for other types of cancers, including solid tumors. Soluble and membrane-bound receptor–ligand immune checkpoints could represent interesting targets for future therapeutic monitoring and for pharmacologic interventions in CML.

Financial Support: FEDER (Programa Operacional Factores de Competitividade – COMPETE) and FCT (Fundação para a Ciência e a Tecnologia) through project PEst-C/SAU/LA0001/2013-2014.

TYROSINE KINASE INHIBITORS SIGNIFICANTLY CHANGE THE EXPRESSION OF POLYCOMB GENES IN CHRONIC MYELOID LEUKEMIA

S. Grassi[1,*], S. Palumbo[2], E. Arrigoni[3], E. Ciabatti[4], G. Ercolano[5], F. Guerrini[4], A. Di Vita[5], S. Pacini[5], M. Montali[5], S. Barachini[5], C. Domenichini[5], G. Tarrini[5], M. Vangeli[5], S. Salehzadeh[5], M. R. Metelli[5], S. Pellegrini[2], F. Ricci[4], C. Baratè[4], V. Mariotti[2], M. Petrini[4], A. Di Paolo[3], S. Galimberti[4]
[1]Medical Biotechnologies, University of Siena, Siena, [2]Clinical and Experimental Medicine, Clinical Biochemistry and Molecular Biology, University of Pisa, [3]Clinical and Experimental Medicine, section of Pharmacology, University of Pisa, [4]Clinical and Experimental Medicine, Hematology, University of Pisa, [5]Clinical and Experimental Medicine, Hematology Molecular Laboratory, AOUP, Pisa, Italy

Background: It has been reported that, notwithstanding their clinical success, tyrosine kinase inhibitors (TKIs) are not able to eradicate the leukemic stem cell (LSC) in patients with chronic myeloid leukemia (CML). Different mechanism have been hypothesized, especially those linked to the niche (increased osteoblastic differentiation, angiogenesis, hypoxia...). The epigenetic control seems to be relevant, and our group previously identified a correlatio between the expression of some polycomb genes (PcGs) and response to TKIs, with BMI1 resulting a good predictive molecular marker (Crea, 2015).

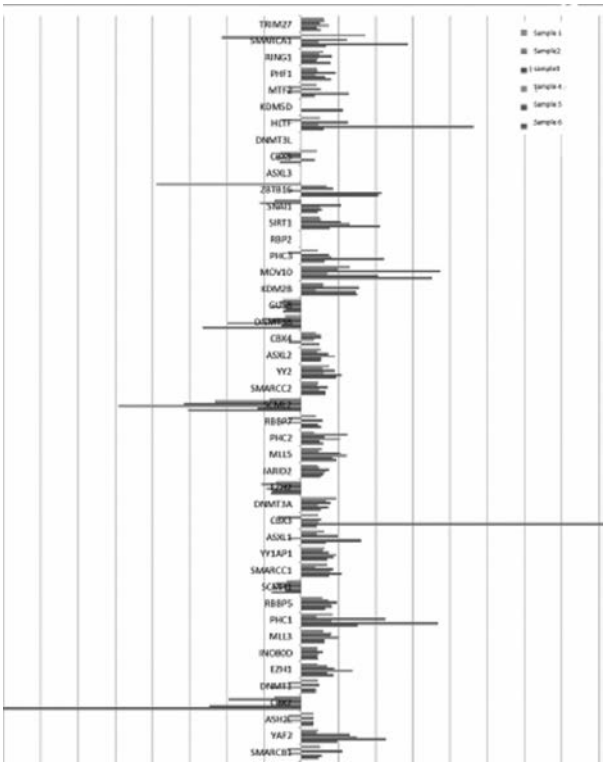

Figure 1.

Aims: In order to better understand the role of the PcGs genes in CML patients receiving TKIs, we analyzed the expression of 86 PcGs at baseline and after 6 months of therapy.
Methods: Buffy coats obtained from peripheral blood samples of 6 patients (5 receiving imatinib and 1 dasatinib) have been used for the RNA extraction; these RNAs were used for quantifying the BCR-ABL1/ABL1 ratio%IS, according to the European guidelines, and the expression of the chosen 86 PcGs by real-time PCR (PrimePCR pathway kit, Biorad, Milan, Italy) at diagnosis and after 6 months of treatment. Expression values were calculated using the 2DDCt method.
Results: At the sixth month of treatment, 5 patients were in optimal response and one was "warning", according to the 2013 ELN guidelines. After therapy, 55% of the tested PcGs resulted up-regulated and 23% of them in the majority of patients; whereas 3 genes (DNMT3B, SCML2, CBX2) were down-regulated in at least half of samples. The expression of 5% of PcGs was "mixed", up- or down-regulated in different samples. Among the up-regulated genes, some could be relevant from a biological point of view: 1) HLTF, a target for RUNX1, whose low expression in acute leukemia is correlated with poor outcome; 2) PHC2, able to silence the HOX genes, overcoming the multidrug resistance in myeloid models; 3) PCGF5, that is a marker of normal hematopoiesis; 4) MOV10, that has been reported to have an anti-viral activity, increasing levels of gamma interferon. This up-regulation is particularly interesting, because concerns all assessed samples and could explain our previous observation that Torque Teno virus replication does not occur in CML patients during TKIs therapy; 5) in the only "warning" patient, the up-regulation of SIRT1 was observed: this is in line with the observation that its up-regulation increases the oncogenic ability of K562 cells in a murine model. Among the down-regulated genes, could be relevant: 1) CBX2, that binding P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB16, whose reduction could be a sign of the reduced osteoblastogenesis, one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels resulted unmodified in 3 cases and increased in other 3.
Summary/Conclusions: We demonstrated that PcGs de-regulation occurs in CML patients during the treatment with TKIs, with possible pathogenetic implications. Huger series of patients will improve the biological suggestions coming from these preliminary data.

E1049

IDENTIFICATION OF PROGNOSTIC AND SUSCEPTIBILITY MARKERS IN CHRONIC MYELOID LEUKEMIA USING NEXT GENERATION SEQUENCING

Y. Shokeen[1,*], N.R. Sharma[2], V. Taneja[3], S. Minhas[1], M. Jauhri[1], S. Aggarwal[1]
[1]Department of Medical Oncology, Sir Ganga Ram Hospital, Delhi, [2]School of Biotechnology and Biosciences, Lovely Professional University, Jalandhar, [3]Department of Research, Sir Ganga Ram Hospital, Delhi, India

Background: Chronic Myeloid Leukemia (CML) is 20% of all leukemias diagnosed every year. Discovery of Imatinib Mesylate has brought a paradigm shift in treatment of Chronic Myeloid Leukemia, despite 15% - 20% patient showing resistance to this TKI. Therefore, it is important to identify susceptibility and prognostic markers, which can help us in predicting occurrence and prognosis of CML. We did Clinical Exome Sequencing, a panel of more than 4800 clinically important genes, in CML patients
Aims: To identify prognostic and susceptibility genetic markers in CML
Methods: Enrolled CML patients (n=18) were segregated as responders (n=10) and failures (n=8) as per ELN, 2013 guidelines. Healthy controls (n=5) were also enrolled. DNA from blood of subjects was subjected Next Generation Sequencing (NGS). Mutations present in one patient group and absent in opposite group were considered as prognostic markers, whereas rare mutations, present in more than 50% of enrolled patients and absent in healthy controls, were considered as susceptibility markers
Results: We discovered mutations in genes associated with cancer or cancer related functions in different patient groups as markers. Five of them: rs116201358, rs17882014, rs4014596, rs52897880 and rs2274329 in C8A, HLA-DRB1, UNC93B1, APOH and CA6 genes respectively, were present in responders; rs4945 in MFGE8 was present in failures. Mutations in HLA-DRB1 (rs17878951, rs11554462, c.239C>G), HLA-DRB5 (rs137863146), RPHN2 (rs193179333), CYP2F1 (rs116958555), KCNJ12 (rs76684759), FUT3 (rs151218854), BMO1 (rs28370522) and PRSS1 (rs144422014) were present in half or more patients
Summary/Conclusions: We discovered potential genetic markers, which can help in predicting response to IM as frontline therapy. Susceptibility markers can be used as panel for to configure individuals prone to CML

E1050

FEATURES OF THE A2455G POLYMORPHISM OF GENE CYP 1A1 IN PATIENTS WITH CML

K. Karimov[1,*], N. Abdurahmanova[1], K. Boboev[1]
[1]institute of hemotology and blood transfuzion, tashkent, Uzbekistan

Background: Chronic myeloid leukemia (CML) is the most common myeloproliferative disorder characterized by the reciprocal translocation t (9; 22), (q34; q11), leading to the formation of chimeric oncogene BCR-ABL on the 22q-chromosome. It is known that the protein products of the genes of cytochromes ensure homeostasis at the cellular and tissue level, carrying out the metabolism of toxic compounds that can damage the genome of the cells. Prognostic value of certain genotypic variants of these genes in the formation of a number of neoplastic diseases, including leukemia. In individuals with weakened functional genotypes of A2455G polymorphism of CYP 1A1 gene expression of this enzyme and, consequently, inactivation of xenobiotic must occur very slowly, thus creating conditions for adverse action of harmful metabolites in the genome of the cells. Currently, the scientific literature discusses the role of the negative allele A2455G polymorphism of CYP 1A1 gene in the development of hematological malignancies. However, the adverse roles of genotypic variants for this gene in oncogenesis of BCR-ABL-positive patients with CML have studied not enough.
Aims: Evaluation the role of A2425G polymorphism of CYP1A1 gene in the formation the mutant clone of tumor and the development of CML.
Methods: The work is performed on DNA samples isolated from the peripheral blood of the patients in the clinic of scientific research Institute of Hematology and blood transfusion in Uzbekistan. We studied 146 patients with CML. The control group was formed from 217 individuals of Uzbek nationality, without of any cancer disease. The diagnosis of CML verified in accordance with the International nomenclature ISCN. Standardized PCR with detection in real-time was carried out on a thermal cycler Rotor-Gene 6000 (Corbett Research, Australia), using a set of reagents "AmpliSens® Leucosis quantum M-bcr-FRT"(InterLabServis, Russia). Testing A2425 polymorphism of CYP1A1 gene was performed on a programmable thermal cycler of the company "Applied Biosystems" (USA) using test systems company "Litech" (Russia) according to the manufacturer's instructions. Statistical analysis of results was carried out using the statistical software package "2009 OpenEpi, Version 2.3".
Results: The frequencies of allele A and G are as follows: 87.7% and 12.3% in patients with CML, and 93.3% and 6.7% in the control group, respectively. The frequency distribution of genotypes A / A, A / G and G / G were as follows: 76.7%, 21.9% and 1.4% - in CML patients, and 86.6%, 13.4% and 0.0% - in the control group. Observed frequencies of genotypes in the studied groups was consistent with the theoretically expected and were in equilibrium with hardy-Weinberg equilibrium (P>0.05). There was a statistically significant decrease in carriage of the adverse alleles in the population sample comparison group patients (1.4% *vs* 6.7%, respectively; χ2=6.8; P=0.01; OR=2.0; 95% CI 1.17- 3.282). Also detected significant association of heterozygous genotype A/G in patients with CML, compared with the control group (21.9% *vs* 13.4%, respectively). The risk of mutant formation of the tumor clone in carriers of this genotype was 1.8 times significantly higher compared with patients not having it (χ2=4.6; P=0.03; OR=1.8; 95% CI 1.046-3.166). The homozygous genotype G/G in the group of patients was significantly more compared to the control group (1.4% *vs* 0.0%), but due to the small number of carriers of this genotype differences in the results did not reach statistical significance (P>0.05). Functionally favorable genotype A/A was found with high frequency in a population-based sample of 86.6% *vs* 76.7% cases of patients. At the same time, the differences reached the threshold level of significance (χ2=6.0; P=0.01; OR=0.5; 95% CI 0.29-0.88), that is evidence of a favorable protective effect of this genotype against the development of CML.
Summary/Conclusions: Our results suggest that the G allele and the heterozygous genotype A/G A2425G polymorphism of CYP 1A1 gene are important markers of increased risk in formation of malignant tumor cells and development of CML in Uzbekistan (P<0.05). In this case, homozygous genotype A/A of A2425G polymorphism of CYP 1A1 gene has a protective character in relation to risk of CML.

Chronic myeloid leukemia - Clinical

E1051

HEMATOLOGIC TOXCITIY GRADE III-IV IS ASSOCIATED WITH LOWER SURVIVAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

Background: TKIs introduction in the treatment of chronic myeloid leukemia (CML) has offered an outstanding improvement in survival outcomes. These results were obtained from clinical trials but little is known about long-term toxicity and their translation to real life. In addition, clinical trials results are mainly based on the analysis of the therapy of interest (experimental or control), but the descriptions of the subsequent treatment sequences due to failure or intolerance are normally lacking.
Aims: To analyze the long-term toxicity of patients outside clinical trials in clinical trials. The setting was a multicentric, hospital-based registry.
Methods: Toxicity grade III-IV and survival and their potentially associated variables were studied.

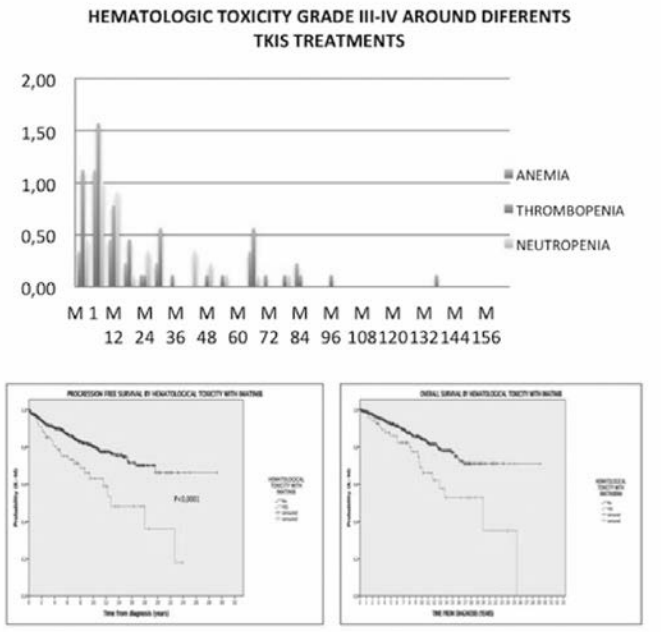

Figure 1. Evolution of hematologic toxicity grade 3-4 with time (all treatments sequences included).

Results: Demographics, risk and treatment distribution: 893 patients (533 men, 360 women) with a median age at diagnosis of 52 y (14-94y) were included with a follow up of 85±7 months (m) from diagnosis, 78±6.6 m from first treatment, and 69±6 m from first TKIs. 151 patients (16,9%) were over 70y. The risk distributions were as follows: Sokal: low (L) 48%, intermediate (I) 37% and high (H) 14%; Euro score: L 50%, I 45% and H 5%; EUTOS L: 92% and H 8%; EUTOS LT: L 70%, I 23% and H 7%. Treatment groups were the following: Group 1: IFN alpha and then imatinib or 2º GTKIs (221 patients); Group 2: imatinib only (404 patients); Group 3: imatinib and then nilotinib, dasatinib or both due to failure or intolerance (177 patients) and Group 4: 2ºGTKIs in first line (93 patients).Hematologic toxicity grade III-IV: Figure 1 shows the incidence through the years (all group of treatments). From 800 patients treated with imatinib (first o second line) 67 (8,3%) had grade III-IV toxicity, and 26 had to switch treatment due to toxicity. From 166 patients treated with dasatinib (29

in1st line, 114 in 2nd, 56 in 3rd) only 13 had hematologic toxicity and 6 had to switch, 14 had pleural effusion grade III-IV and 9 had to switch. From 115 patients treated with nilotinib (49 in 1st line and 66 in 2nd) only 10 had hematologic toxicity and 10 switched treatment. Survival: Estimated survival by 10 years was 80%. Variables associated with survival: In the univariate survival analyses (log rank test) either from diagnosis, first therapy or first TKIs, the Sokal, Eutos, Euro and EUTOS LT scores, as well as age over 70y were the only statistically significant variables associated with survival. Hematology toxicity grade III-IV was associated with lower PFS or OS (figure 1). In the multivariate analysis (Cox model), only hematology toxicity grade III-IV and age over 70y were independent variables.

Summary/Conclusions: 1.These results show that the probability of survival by 10 years is roughly 80%, and extend the findings of our previous work showing that this probability is not different across different sequential treatments (imatinib 1st line or post-IFN, or switched to 2ªGTKis due to intolerance o failure) (1). This fact emphasizes the rescue potential of available TKI therapies. 2. Hematologic toxicity grade III-IV in the first two years identified a group of patients with worse survival outcome. 3. Patients over 70 years have shorter survival due to reasons different than progression. 4 Second GTKIs showed better hematologic toxicity profile.

E1052

5-YEAR EFFICACY OF DASATINIB AND IMATINIB IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) WITH DOSE MODIFICATIONS FROM DASISION

A. Hochhaus[1,*], E. Jabbour[2], H. Kantarjian[2], F. Guilhot[3], V. Kota[4], T. P. Hughes[5], S. Shelat[6], L. Li[6], J.E. Cortes[2]
[1]Universitätsklinikum Jena, Jena, Germany, [2]University of Texas MD Anderson Cancer Center, Houston, United States, [3]Inserm CIC 1402, CHU de Poitiers, Poitiers, France, [4]Winship Cancer Institute at Emory University, Atlanta, United States, [5]SAHMRI, University of Adelaide, Adelaide, Australia, [6]Bristol-Myers Squibb, Princeton, United States

Background: Multiple dosage strengths are approved for dasatinib (DAS), permitting dose-optimization strategies for patients who experience adverse events (AEs). In a 2-year retrospective analysis of DASISION, efficacy was maintained in DAS- and imatinib (IM)-treated patients with dose reductions or interruptions to manage AEs (Jabbour ASH 2011); cytogenetic and molecular response rates were higher for patients given DAS *vs* IM, even when daily doses were modified. Longer term follow-up is needed to fully understand the potential impact of dose reductions on efficacy.

Aims: To evaluate the effect of dose reduction for any AE and for pleural effusion on efficacy in DAS- or IM-treated patients from DASISION.

Methods: Treatment-naïve patients with CML-CP in DASISION (NCT00481247) were randomized to receive either DAS (100mg once/day; N=259) or IM (400mg once/day; N=260). Dose reductions for AEs (up to 2) were allowed: DAS: 80mg, then 50mg; IM: 300mg, then 200mg. Five-year molecular and cytogenetic response rates in all patients were assessed retrospectively.

Table 1.

Results: Patients on DAS maintained higher molecular response rates than patients on IM, whether or not they had dose reductions for an AE; these rates were similar in patients with and without dose reductions in each arm (table). 95 (37%) DAS- and 44 (17%) IM-treated patients had dose reductions at any time due to AEs. Median time to first DAS dose reduction was 289 days (range: 22-2123), and median time to first IM dose reduction was 160 days (range: 31-2052). For patients with reductions due to any cause, median average daily dose was DAS 83mg and IM 328mg; for DAS patients with reductions due to pleural effusion, median average daily dose was 82mg. Median duration of treatment (excluding interruptions) was 54 months (range: 3-70) for patients who had a DAS dose reduction and 57 months (range: 2-71) for patients who had an IM dose reduction. Changes in level of response were tracked for patients who achieved complete cytogenetic response (CCyR) or major molecular response (MMR) before or after the first dose reduction (table). Many patients maintained or increased to CCyR or MMR following dose reductions for any AE. Hematological toxicity (9%) was the most common AE resulting in dose reduction for IM, and pleural effusion (12%) was the most common for DAS.

Summary/Conclusions: Reducing DAS doses to 80mg or 50mg was a safe and effective means of managing patients who experienced AEs in this 5-year retrospective analysis of DASISION. These results were consistent with previous reports and continued to show that efficacy was not affected by dose reductions for any cause, including pleural effusion. Notably, there was no loss of CCyR following dasatinib dose reductions. Molecular responses remained higher for DAS *vs* IM irrespective of dose reductions due to AEs.

E1053

EFFECT OF PLASMA TROUGH CONCENTRATION OF NILOTINIB AND POLYMORPHISMS OF DRUG TRANSPORTER GENES ON THE FREQUENCY OF ADVERSE EVENTS IN CHRONIC PHASE OF CHRONIC MYELOID LEUKEMIA: STAT1 AND STAT2 TRIALS

N. Takahashi[1,*], T. Niioka[2], M. Abumiya[2], S. Takahashi[1], M. Miura[2]
[1]Hematology, AKITA UNIV., [2]Pharmacy, AKITA UNIV. HOSPITAL, Akita, Japan

Background: STAT trials (STAT1 and STAT2) are multicenter, phase II, single-treatment arm, open-label clinical studies designed to evaluate the efficacy and safety of two-year consolidation by nilotinib (NIL) for achieving a deep molecular response (DMR) or successful treatment-free remission (TFR) in patients with chronic phase chronic myeloid leukemia (CML).

Aims: In this report, we focus on the adverse events (AEs), especially anemia and liver dysfunction observed in the STAT trials. Additionally, we analyzed the relationship between laboratory abnormalities and pharmacokinetics (PK)/ phramacogenetics (PGx) of NIL.

Methods: AEs were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) v4.03. Safety evaluations were conducted throughout the study. Plasma trough concentrations of NIL were determined with high-performance liquid chromatography (HPLC) at 1 month (1M), 3M, 6M, 12M, and 24M in the STAT trials. Genotyping of *CYP3A5*3* [*6986A>G* (rs776746)], *ABCB1* [*3435T>C* (rs1045642)], *ABCG2 421C>A* (rs2231142), and *UGT1A1*6*, **27,* and **28* was performed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). All genotype frequencies were tested for Hardy-Weinberg equilibrium.

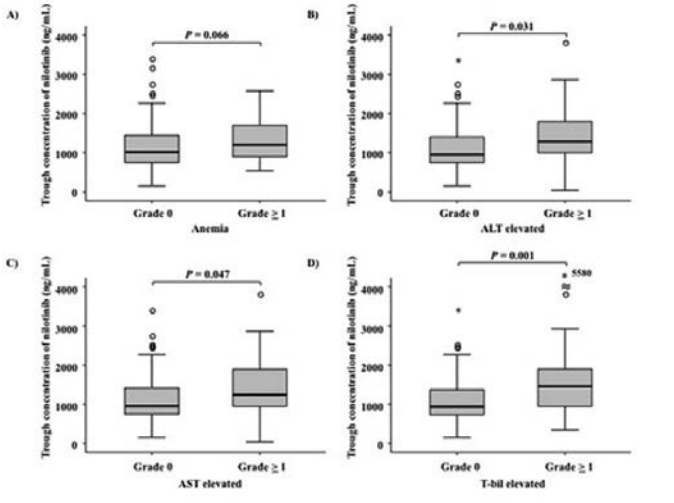

Figure 1.

Results: Between July 2011 and December 2012, CML patients were recruited in the STAT trials. NIL was administered twice daily (600mg/day) for 2 years according to the study protocol. A total of 76 and 96 patients were analyzed as a safety data set in STAT1 and STAT2, respectively. In STAT1, 18 patients who achieved a confirmed DMR were switched from STAT1 to STAT2. These patients entered both trials, but safety data had not been collected in STAT1 after entering STAT2 to avoid double counts. The PK/PGx data of 147 of 154 patients were available and were evaluated in this study. Median trough concentrations of NIL were 1265 ng/ml at 1M, 1154 ng/ml at 3M, 974 ng/ml at 6M, 735 ng/ml at 12M, and 781 ng/ml at 24M. Although any-grade AEs were reported in 43 patients in STAT1 and 55 patients in STAT2, the most common drug-related hematological and non-hematological AEs were elevated total bilirubin (28.6%), anemia (24.5%), elevated ALT (21.1%), and elevated AST (18.4%). The incidence of these AEs, except for anemia, was significantly associated

with high trough concentration of NIL (Figure1). There were statistically significant correlations between median concentrations of NIL and the grades of each AE. Based on the results of the analysis using Cox proportional-hazards model, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), *P*=0.004] and *ABCG2* 421A/A [hazard ratio=3.044 (1.155-8.027), *P*=0.024] were independent factors for the elevated ALT. Similarly, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), *P*<0.001] and *UGT1A1 *1/*1* [hazard ratio=0.475 (0.246-0.919), *P*=0.027] were independent factors for the elevated total bilirubin.
Summary/Conclusions: In this study, we identified the relationship between NIL trough concentration and liver dysfunction. Our finding suggests that therapeutic drug monitoring might help avoid drug interruption and discontinuation because of AEs, especially liver dysfunction.

Background: In BCR-ABL1 tyrosine kinase inhibitor (TKI) treated chronic phase chronic myeloid leukemia (CP-CML), early molecular response (EMR) at 3 month is currently identified as being one of the most important prognostic factors. Sokal risk score and dose intensity during first 3 months were strongly associated with achievement of EMR. As dasatinib is a novel, oral tyrosine kinase inhibitor with improved potency, identification of very early molecular response (VEMR) would be beneficial.
Aims: We evaluated the possibility of the VEMR at 1 month predicting long-term outcomes in newly diagnosed CP-CML patients treated with dasatinib.
Methods: In this multi-center, observational, open-label study, 102 patients with CP-CML were enrolled to receive dasatinib at a dose of 100mg once daily. The primary end point was complete molecular response (CMR) by 18 months. Secondary end points including molecular response (MR) by 1, 3, 6, 12, 18, 24 month, time to and duration of MMR and CMR, and safety were tested. A receiver operating characteristic (ROC) curve from BCR-ABL1 transcript level on Day+28 was calculated to predict EMR and MMR at specific timepoints.
Results: Median age was 49 years (19-81 years) and 61 patients were male. With median follow-up duration of 28 months (0.9-33.8 months), 80 (78.4%) out of 102 patients were still on dasatinib treatment and 22 patients discontinued due to disease progression (n=2) or treatment failure (n=3) or adverse events (n=8) or other reasons (n=9). The BCR-ABL1 mutations, assessed in 10 patients after dasatinib discontinuation, were detected in 3 patients which were all T315I mutation. The cumulative CMR by 18 months and MMR by 24 months were 20.5% and 79.6% respectively. In safety analyses, grade 3/4 thrombocytopenia (30.3%) was most common. Pleural effusion occurred in sixteen (15.6%) patients which were mostly grade 1/2. The cut-off value of BCR-ABL1 transcript on Day+28 was 40% by ROC curve analysis. Among 95 patients who had available molecular data of both D+28 and 12 months, fifty nine (62.1%) patients had less than 40% of BCR-ABL1 transcript (VEMR) on Day+28. Among them, 49 (83.1%) patients achieved MMR at 12 months. However, only 27.8% (10 out of 36 patients) of patients without VEMR achieved MMR (p<0.0001). Among 85 patients who had available molecular data of both D+28 and 24 months, fifty two (61.2%) patients achieved VEMR. In 52 VEMR patients, 46 (88.5%) patients achieved MMR at 24 months. However, only 48.5% (16 out of 33 patients) of patients without VEMR achieved MMR (p=0.0001). Overall survival (OS) & progression-free survival (PFS) rates by 24 months were 98.0% and 95.1% respectively. PFS rates by 24 months for VEMR and no VEMR group were 98.4% *vs* 88.8% respectively (p=0.04).
Summary/Conclusions: Our study shows that VEMR at 1 month can be a strong predictor for further molecular responses as well as long-term outcome. Therefore it would be helpful to monitor BCR-ABL1 transcript level at 1 month in patients who treated with more potent TKIs.

E1055

SURVIVAL OUTCOMES IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) RECEIVING THIRD- OR SUBSEQUENT LINE (3L) TREATMENT PRIOR TO THE AVAILABILITY OF PONATINIB

D. Stellato[1], L. McGarry[2,*], H. Huang[2], S. Hastings[1], T. Delea[1]
[1]Policy Analysis Inc. (PAI), Brookline MA, [2]ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: PACE was a phase 2 single-arm trial of ponatinib, a 3rd-generation tyrosine kinase inhibitor (TKI), in 449 highly-refractory patients with CML or Philadelphia-chromosome positive (Ph+) acute lymphocytic leukemia (ALL) or who had the BCR-ABL T315I mutation. Overall survival (OS) for 3L CP-CML patients in PACE at 1, 2, 3 and 4 years was estimated to be 91%, 83%, 80%, and 79%, respectively. Expected survival for 3L CP-CML patients prior to the availability of ponatinib has not been documented.
Aims: To estimate OS in patients with CP-CML receiving 3L treatment prior to ponatinib via a systematic literature review.
Methods: Studies were identified from a review by Lipton *et al.* (2015), updated with studies identified from searches of electronic databases (MEDLINE, EMBASE, Cochrane Libraries) and abstract databases of key conferences. Landmark and median survival were extracted from study reports. Pseudo-individual patient data (IPD) for survival outcomes were derived from digitized Kaplan-Meier (KM) survival curves then pooled and analyzed using KM methods.
Results: Fifteen studies (717 patients) were identified that reported median, landmark, or KM curves for survival outcomes for CP-CML patients receiving 3L treatment without ponatinib. KM curves for OS were obtained for 6 arms (3 nilotinib and/or dasatinib; 3 other TKIs). OS at 1, 2 and 3 years based on the pooled IPD is reported in the Table. To avoid confounding of OS from post-progression treatment with ponatinib, 1 study was excluded that included follow-up after the date of ponatinib's approval.

Table 1.

Table. Estimated OS in CP-CML patients receiving 3L treatment prior to ponatinib

Time (Years)	OS		
	Pts	Arms	Probability (95%CI)
0	327	5	100% (-- , --)
1	257	5	90% (86%, 93%)
2	179	5	77% (72%, 83%)
3	89	2	66% (59%, 72%)

Summary/Conclusions: Estimated OS in patients with CP-CML receiving 3L treatment prior to ponatinib appears to be shorter than that observed among ponatinib-treated patients in PACE: 4-year survival probability in PACE is higher than estimated 2-year survival probability prior to ponatinib. Further analyses are needed to identify and adjust for potentially confounding factors.

E1056

DETECTION AND MONITORING OF BCR-ABL1 KINASE DOMAIN MUTATIONS IN CML AND ALL PATIENTS BY NEXT GENERATION SEQUENCING AND DROPLET DIGITAL PCR, A BELGIAN PROSPECTIVE STUDY

C. De Rop[1,*], H. Devos[2], P. Vannuffel[1], F. Nollet[2]
[1]Molecular Biology, IPG, Gosselies, [2]Laboratory Medecine, AZ Sint-Jan, Bruges, Belgium

Background: Among myeloproliferative diseases, development of chronic myeloid leukaemia (CML) is associated with the emergence of the fusion oncogene *BCR-ABL1* resulting from a t(9,22) chromosomal translocation (Philadelphia chromosome). This chimeric transcript is also present in all acute lymphoblastic leukaemia (ALL) patients bearing a Philadelphia chromosome (Phi+ ALL). Mutations of the *BCR-ABL1* kinase domain constitute a major cause of treatment failure in CML and Phi+-ALL patients receiving first or second generation tyrosine kinase inhibitor (TKI) treatment. So far, the gold standard procedure to detect *BCR-ABL1* kinase domain (KD) mutations is the conventional Sanger Sequencing, endowed with an analytical sensitivity of 15-20%. Recent studies on the implementation of Next Generation Sequencing (NGS) for detection of BCR-ABL1 KD mutations showed a significant dropping down of the sensitivity level (1-5%), improving patient's treatment management.

Aims: Both NGS and droplet digital PCR (ddPCR) were used in this prospective study. NGS screened all known mutations in the *BCR-ABL1* KD and ddPCR targeted only the 3 most common mutations, T315I, E255K and Y253H, which represent approximatively 75% of the *ABL1* mutations. Patients eligible for the study were i) CML patients with failure or warning to all lines of TKI therapy according to the 2013 ELN-guidelines, with no suspected lack of adherence and ii) Phi+ ALL patients at diagnosis and/or molecular relapse. Monitoring was performed when clinically appropriate.
Methods: Total *BCR-ABL1* RNA was transcribed into a long range cDNA covering the kinase and the regulatory and the SH2/SH3 domains of either p190 or p210 *BCR-ABL1* transcripts (exons 4 to 10). For NGS, primers designed with the Ampliseq™ Designer Software generated a set of 10 amplicons. Barcoded libraries, constructed according to the AmpliSeq™ protocol, were sequenced on the Ion Torrent PGM platform (sensitivity of 2.5%). For ddPCR, cDNA was analysed for the presence of one of the 3 main mutations (T315I, E255K and Y253H) on the Bio-Rad QX200 platform (sensitivity of 1%).
Results: The participation of more than 20 Belgian centres allowed the inclusion of 60 samples on a 9 months period (54 CML and 6 Phi+ ALL). The overall number of *BCR-ABL1* mutated samples was 18 (15 CML and 3 Phi+ ALL), representing 30% of the cases. Among these samples, 27 mutations were found. 9 samples presented with one mutation: T315I (2), E255K (3), G250V (1), F359I (1), M237T(1) and E255A (1) and 9 harboured compound mutations: T315I + E255K (6) and T315I + Y253H (3). A high frequency (85%) of T315I, E255K and Y253H mutations was also observed (23/27). As far as these 3 mutations are concerned, reproducibility to determine mutational burden was found to be very high between NGS and ddPCR.
Summary/Conclusions: Advances in sequencing technologies and further lowering sensitivity levels contribute to optimal management of CML and Ph+ ALL patients and improve treatment outcome. The earlier a mutation in the kinase domain is detected, the earlier an informed choice can be made regarding optimal subsequent TKI treatment.

E1057

CLINICAL AND IMMUNOLOGICAL EFFECTS OF NILOTINIB IN COMBINATION WITH PEGYLATED INTERFERON-A2B IN PATIENTS WITH SUBOPTIMAL MOLECULAR RESPONSE ON IMATINIB (NORDDUTCHCML009)

I. Geelen[1,*], U. Olsson-Strömberg[2], S. Mustjoki[3,4], J. Richter[5], N. Blijlevens[6], W. Smit[7], B. Gjertsen[8,9], T. Gedde-Dahl[10], B. Markevärn[11], M. Koppes[12], P. Westerweel[1], J. Janssen[12], H. Hjorth-Hansen[13,14]
[1]Albert Schweitzer Hospital, Dordrecht, Netherlands, [2]Department of Hematology, Uppsala University Hospital, Uppsala, Sweden, [3]Hematology Research Unit Helsinki, University of Helsinki and Helsinki University Hospital Comprehensive Cancer Center, [4]Department of Clinical Chemistry, University of Helsinki, Helsinki, Finland, [5]Department of Hematology and Vascular Disorders, Skåne Univeristy Hospital, Lund, Sweden, [6]Department of Hematology, Radboud UMC, Nijmegen, [7]Department of Hematology, Medical Spectrum Twente, Enschede, Netherlands, [8]Department of Internal Medicine, Hematology Section, Haukeland University Hospital, [9]Department of Clinical Science, University of Bergen, Bergen, [10]Department of Hematology, Oslo University Hospital, Rikshospitalet, Oslo, Norway, [11]Department of Hematology, Umeå University Hospital, Umeå, Sweden, [12]Department of Hematology, VU Medical Center, Amsterdam, Netherlands, [13]Department of Hematology, St. Olavs Hospital, [14]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology (NTNU), Trondheim, Norway

Background: The ability to "cure" a proportion of chronic myeloid leukemia patients (CML) makes treatment free remission (TFR) an important treatment goal which requires sustained deep molecular response on TKI therapy. Unfortunately, not all patients achieve deep molecular responses on their first line treatment. Novel treatment strategies to increase the proportion of CML patients eligible for a TKI stop attempt are therefore needed.
Aims: The primary objective of the NordDutchCML009 study was to assess if, in CML patients who did not achieve an $MR^{4.0}$ or better to imatinib could attain this $MR^{4.0}$after a switch to nilotinib with pegylated interferon-α2b (pegIFN-α2b) combination treatment for at least 12 months. Assessment of safety, tolerability and immunological effects of the combination treatment were additional study goals.
Methods: In a phase II, single arm, multicenter trial, patients with *BCR-ABL1* levels above 0.01% (IS) after at least two years of imatinib treatment were switched to nilotinib 300mg BD (Nilo). PegIFN-α2b (Peg) 25 µg/week was introduced after three months, increased to 40 µg/week at month 6 if tolerated and continued until month 12. Adverse events were assessed according to CTCAE version 3. Flow cytometry assessments of T-, NK- and B-cell populations, activated T-cells, myeloid-derived suppressor cells (MDSCs) and regulatory T-cells (Tregs), cytotoxicity assays of NK-cells against K562 target cells, IFN-γ production analysis of stimulated CD3+ cells (Elispot), and Granzyme B staining of T-cells were performed at baseline (imatinib), 3 months (nilotinib) and 6 months (nilotinib + pegIFN-α2b) after inclusion and compared using a repeated measures ANOVA with multiple comparisons.
Results: In total 16 patients were enrolled in the study. Recruitment of patients was difficult and the study was prematurely closed for this reason. Confirmed $MR^{4.0}$ at 12 months was achieved by 50% (7/14) of the patients. Two patients discontinued nilotinib treatment within the first 3 months due to hepatotoxicity and lipase elevation (grade 4). Five patients did not tolerate PegIFN-α2b combination treatment, mainly due to mood disturbances. Finally, only 56% of patients completed the scheduled Nilo/Peg combination treatment for the first 12 months. We found a reduction in the proportion of CD56+ NK-cells after addition of PegIFN-α2b to the nilotinib treatment (*P*=.046), but no significant changes in the other immunological parameters. In the subgroup analysis this finding only demonstrated as a trend for a decreased NK-cell count after PegIFN—α2b administration in patients who attained confirmed $MR^{4.0}$ at 12 months (p=0.063), and was not established in patients who did not attain confirmed $MR^{4.0}$ at 12 months. In those patients who did not attain confirmed $MR^{4.0}$ at 12 months, we observed an increased number of stimulated CD3+ cells producing IFN-γ after introduction of PegIFN-α2b (p=0.026). These results from the subgroup analysis need to be interpreted with caution due to low statistical power.
Summary/Conclusions: Despite relatively poor tolerability of the scheduled Nilo/Peg combination treatment in the current study, CD56+ NK cells were significantly modulated and more than half of the patients achieved a sustained $MR^{4.0}$, which would allow for a TKI stop attempt. The discontinuation rate suggests that the PegIFN dose was too high in combination with nilotinib treatment in our study population.

ANALYSIS OF VASCULAR ADVERSE EVENTS IN TKI TREATED JAPANESE CML PATIENTS: RETROSPECTIVE LARGE COHORT STUDY OF CML COOPERATIVE STUDY GROUP

I. Fujioka[1,*], T. Takaku[1], N. Iriyama[2], M. Tokuhira[3], E. Sato[4], M. Ishikawa[5], T. Nakazato[6], K.-J. Sugimoto[7], H. Fujita[8], N. Asou[5], M. Kizaki[3], Y. Hatta[2], N. Komatsu[1], T. Kawaguchi[9]
[1]Department of Hematology, Juntendo University School of Medicine, [2]Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Tokyo, [3]Department of Hematology, Saitama Medical Center, Saitama Medical University, Saitama, [4]Division of Hematology, Department of Medicine, Juntendo University Nerima Hospital, Tokyo, [5]Department of Hemato-Oncology, Comprehensive Cancer Center, Saitama Medical University International Medical Center, Saitama, [6]Department of Hematology, Yokohama Municipal Citizen's Hospital, Yokohama, [7]Department of Hematology, Juntendo University Urayasu Hospital, Urayasu, [8]Department of Hematology, Saiseikai Yokohama Nanbu Hospital, Yokohama, [9]Department of Hematology and Infectious Diseases, Kumamoto University Hospital, Kumamoto, Japan

Background: Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells resulting from oncogenic chromosome translocation that leads to the formation of the *BCR-ABL1* fusion gene.Treatment of chronic phase (CP) CML has dramatically changed since the emergence of the first-in class tyrosine kinase inhibitor (TKI) imatinib, and treatment based on TKI has improved the outcome in the majority of CP-CML patients. Nowadays, second generation TKIs are available and brought about faster and deeper clinical responses, and lower disease progression rate than imatinib. On the other hand, longer treatment duration and the increased types of TKIs gave rise to various kinds of unexpected adverse events (AEs). In 2011, drug-induced peripheral artery occlusive disease (PAOD) was first reported, followed by vascular AEs (VAEs) including ischemic heart disease (IHD) and cerebral infarction (CI). Furthermore, it became clear that the incidence of VAEs increased with the dose and treatment duration, therefore VAEs are considered a more fatal complication of TKI treatment. However, there is no available data about the incidence of VAEs in Japanese patients.
Aims: We investigated the vascular safety issue and estimated the 1000 person-years risk of developing VAEs during TKI treatment, including imatinib, nilotinib, and dasatinib, using 3 risk assessment tools among 320 Japanese patients who were enrolled in the CML Cooperative Study Group.
Methods: A surveillance data of 320 patients enrolled in the CML Cooperative Study Group was conducted in this analysis. Briefly, the study included patients who were diagnosed with CML-CP from April 2001 to January 2016, whose median age was 57 years old (15-80) and median time of follow up was 64.2 months. Patients in the accelerated or blastic phase (AP/BP) were excluded. The study was approved by the research ethics boards of each institutions and was conducted in accordance with the Declaration of Helsinki. All patients who developed VAEs were analyzed using 3 risk assessment tools (SCORE chart, Framingham risk score, Suita-score) to estimate the patients' 10-year risk of VAEs.
Results: Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 3 cases by nilotinib, 1 case by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (3 low, 5 moderate, 7 high risk), and Suita-score (13 low, 1 intermediate, 1 high risk). The incidence rate of IHD and CI per 1000 person-years were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-

matched general population, respectively. Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 3 cases by nilotinib, 1 case by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (3 low, 5 moderate, 7 high risk), and Suita-score (13 low, 1 intermediate, 1 high risk). The incidence rate of IHD and CI per 1000 person-years were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-matched general population, respectively.

Table 1.

Incidence rate of VAEs

	Control	CML patient (N = 320)			Imatinib (N = 155)			Nilotinib (N = 105)			Dasatinib (N = 127)		
	Incidence rate *1	Events	Exposure Time (yr)	Incidence rate *1	Events	Exposure time (yr)	Incidence rate *1	Events	Exposure Time (yr)	Incidence rate *1	Events	Exposure Time (yr)	Incidence rate *1
All thrombotic events		16	1711	9.35	7	860	8.14	8	279	28.67	1	245	4.08
IHD	1.787*2	9	1711	5.26	4	860	4.65	4	279	14.34	1	245	4.08
CI	3.342*3	5	1711	2.92	2	860	2.33	3	279	10.75	0	245	0
PAOD	N/A	2	1711	1.17	1	860	1.16	1	279	3.58	0	245	0

*1 incidence rate per 1000 person-year
*2 TAKASHIMA AMI registry 1990-2001 Am J Epidemiol 2008;167:1358-1364
*3 TAKASHIMA stroke registry 1988-2004 Stroke 2010;41:1871-1876
N/A: no available data
yr: years

Summary/Conclusions: The incidence rate of IHD per 1000 person-years were higher in the nilotinib- and lower in imatinib- and dasatinib-treated CML patients, and the patients showed almost the same rate of CI as compared with the age-matched general population, even though the incidence of VAEs were lower in Japanese as compared to the European cohort. More patients were estimated to have very-high and high risk of VAEs in the SCORE and Framingham risk score assessment tools as compared with the Suita-score tool.

E1059

UPDATE OF CMREGISTRY: AN OBSERVATIONAL, MULTI CENTER, PROSPECTIVE FOLLOW-UP REGISTRY OF PATIENTS WITH CHRONIC PHASE CML WITH A HIGH PROBABILITY OF OBTAINING A DEEP MOLECULAR RESPONSE >CMR4 (IS)

J.M. Alonso-Dominguez[1,*], E. Olavarria[2], M. Perez Encinas[3], R. de Paz Arias[4], R. Ayala Diaz[5], L.F. Casado Montero[6], F. Ferrer Marin[7], G. Bautista[8], V. Conesa Garcia[9], C. Mba[10], J.L. Steegmann[11]
[1]Hematology Department, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [2]Hematology Department, Hammersmith Hospital, London, United Kingdom, [3]Hematology Department, Hospital Clinico de Santiago, Santiago, [4]Hematology Department, Hospital La Paz, [5]Hematology Department, Hospital Doce de Octubre, Madrid, [6]Hematology Department, Hospital Virgen de la Salud, Toledo, [7]Hematology Department, Hospital Morales Meseguer, Murcia, [8]Hematology Department, Hospital Puerta Hierro, Madrid, [9]Hematology Department, Hospital General de Elche, Elche, [10]Hematology Department, Fundación Investigación Hospital de la Princesa IIS-IP, [11]Hematology Department, Hospital de la Princesa, Madrid, Spain

Background: Since the introduction of Tyrosine Kinase Inhibitors (TKI), many patients diagnosed of Chronic Myeloid Leukemia (CML) in chronic phase achieve a deep molecular response. Around 50% of these patients are expected to maintain their molecular responses even after discontinuation of their TKI treatment. Several clinical trials are exploring the best way of stopping TKI therapy and evaluating patient and disease characteristics that could predict relapse after treatment discontinuation.
Aims: This is an update of the CMRegistry study aimed at collecting clinical data and molecular information from spanish CML patients that have achieved a series of molecular milestones to any of the tyrosine kinase inhibitors in order to monitor their progress and the achievement of a stable deep molecular response: >MR4 (IS).
Methods: CMRegistry is an observational, multi-center and prospective study. CML patients treated with any of the tyrosine kinase inhibitors who are likely to achieve, or have already achieved, a deep molecular response (>MR4.0 (IS)) are included. This likelihood of achieving >MR4 is defined, for the purposes of the study, as a bcrabl/abl ratio of: 1) ≤1% at 3 months from start of TKI therapy; 2) ≤0.1% at 6 months from start of TKI therapy; or 3) ≤0.01% any time point during treatment. Clinical data have been collected using a specific CRF. All data were registered in an anonymous manner. The BCR-ABL ratios in the IS have been provided by standardized labs in Spain.
Results: From June 2014 to Februay 2017, 976 patients were registered in the study. Median age was 51 years (15-88). The Sokal risk groups were as follows: 345 patients low risk, 307 intermediate risk and 129 high risk. Eutos classification yielded 714 patients in the low risk and 79 in the high risk categories. The majority of patients received first-line treatment with imatinib (626 patients), dasatinib (39 patients) or nilotinib (87 patients). Of note, 5 patients received bosutinib, 1 patient ponatinib and 74 patients were treated with Interferon previous to TKI administration. So far 14 patients have died of non-CML related conditions such as carcinoma (2 patients), ischemic heart disease, respiratory failure and sepsis. Interestingly, 2 patients developed progression of their CML to accelerated phase and blast crisis (1 patient each) with no deaths. At present, 104 patients (11%) have achieved a MR4.0, 174 patients (18%) a MR4.5 and 123 patients (13%) have obtained a complete molecular remission (undetectable bcr-abl transcripts with a sensitivity of at least 10^{-5}).
Summary/Conclusions: Almost one thousand CML patients have been included in this spanish prospective study owing to their promising molecular response that would predict for a sustained deep molecular remission. Four hundred and one patients have already achieved a deep molecular response (>MR4 (IS)) and could be enrolled in prospective discontinuation studies.

E1060

ANALYSIS OF DASATINIB AND IMATINIB 5-YEAR EFFICACY AND SAFETY BASED ON BASELINE COMORBIDITY AND AGE IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) IN DASISION

G. Saglio[1,*], J.E. Cortes[2], A. Hochhaus[3], N.P. Shah[4], E.L. Atallah[5], M. Abaskharoun[6], L. Li[6], M.J. Mauro[7]
[1]University of Turin, Turin, Italy, [2]The University of Texas MD Anderson Cancer Center, Houston, United States, [3]Universitätsklinikum Jena, Jena, Germany, [4]University of California San Francisco School of Medicine, San Francisco, [5]Froedtert & the Medical College of Wisconsin, Milwaukee, [6]Bristol-Myers Squibb, Princeton, [7]Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients with CML often have comorbidities, which may influence treatment-related decisions and impact response and survival. In a retrospective analysis of 1-year data from the phase 3 DASISION study, the overall safety or response in dasatinib- or imatinib-treated patients was not substantially impacted by baseline comorbidities, although certain adverse events (AEs) trended higher in patients with ≥1 *vs* 0 comorbidities (Khoury ASH 2010). Further analysis is warranted to determine how comorbidities may impact long-term outcomes.
Aims: To evaluate the impact of baseline comorbidities and patient age on 5-year safety and efficacy in dasatinib- or imatinib-treated patients from DASISION.
Methods: In DASISION (NCT00481247), patients were randomized to receive dasatinib 100mg/day (N=259) or imatinib 400mg/day (N=260). For this retrospective analysis, patients were grouped as having 0 or ≥1 baseline comorbidity, by baseline disorder (diabetes mellitus, hepatobiliary disease, hyperlipidemia, cardiovascular disorder, or pulmonary condition), or by age group (<46 years, 46–65 years, >65 years). Safety (treatment-related AEs in ≥10% of patients) and efficacy (response rates by 5 years and median times to response) were assessed for each group and treatment.

Table 1.

	DASATINIB				IMATINIB			
	Comorbidities							
	≥1 (n = 192)		0 (n = 66)		≥1 (n = 192)		0 (n = 66)	
Median average dose, mg/day	99		100		400		400	
Discontinuation, %	39		38		36		39	
Responses	≥1 (n = 193)		0 (n = 66)		≥1 (n = 193)		0 (n = 67)	
Response by 5 years, n (%)								
CCyR	171 (89)		57 (86)		165 (85)		53 (79)	
MMR	148 (77)		49 (74)		130 (67)		36 (54)	
$MR^{4.5}$	88 (46)		21 (32)		70 (36)		15 (22)	
Median time to response, months								
CCyR	3		3		6		6	
MMR	9		9		15		20	
$MR^{4.5}$	35		36		47		42	
AEs	≥1 (n = 192)		0 (n = 66)		≥1 (n = 192)		0 (n = 66)	
AE, n (%)	All grade	Grade 3/4	All grade	Grade 3/4	All grade	Grade 3/4	All grade	Grade 3/4
Pleural effusion	64 (33)	5 (3)	9 (14)	2 (3)	2 (1)	0	0	0
Rash	27 (14)	0	3 (4)	0	25 (13)	3 (2)	12 (18)	0
Peripheral edema	19 (10)	0	2 (3)	0	21 (11)	1 (1)	5 (8)	0
Muscle spasms	14 (7)	0	0	0	46 (24)	1 (1)	9 (14)	0
Face edema	12 (6)	0	1 (1)	0	24 (13)	0	2 (3)	0
Eyelid edema	5 (3)	0	1 (1)	0	34 (18)	0	4 (6)	0

CCyR=complete cytogenetic response; MMR=major molecular response (*BCR-ABL1* ≤0.1% International Scale [IS]); $MR^{4.5}$=*BCR-ABL1* ≤0.0032% IS.

Results: The number of patients with 0 or ≥1 comorbidity was similar in the dasatinib (66 [25%]; 193 [75%]) and imatinib (67 [26%]; 193 [74%]) arms, respectively; most (>90%) patients were <65 years old. In patients with 0 or ≥1 baseline comorbidity, the median average daily dose was comparable within arms and discontinuation rates (36%–39%) were similar within and across arms (table). The overall safety profiles were comparable in the 0 and ≥1 comorbidity groups in both arms, other than specific AEs, which had a ≥2 times higher frequency in patients with ≥1 *vs* 0 comorbidities; the majority of these were grade 1/2 AEs (table). The incidence of peripheral edema increased with patient age for both imatinib and dasatinib (<46 years: 5% each; 46–65 years: 12% and 10%; ≥65 years: 21% and 20%). In this analysis, the increased incidence of pleural effusion (PE) in dasatinib-treated patients was most highly associated with increased age: <46 years (16%) *vs* 46–65 years (37%) *vs* >65 years (60%). PE incidence did not appear to be related to baseline pulmonary comorbidity and was similar in dasatinib-treated smokers (33%) *vs* nonsmokers (27%). Within each arm, patients with 0 or ≥1 comorbidity (table) and across age groups had similar response by 5 years, although rates were numerically higher for patients with ≥1 *vs* 0 comorbidities in both arms ($MR^{4.5}$ on dasatinib: 46% *vs* 32%; $MR^{4.5}$on imatinib: 36% *vs* 22%). Median time to response (months) for patients with 0 or ≥1 comorbidity did not differ within each arm, but was numerically shorter for dasatinib ($MR^{4.5}$; 36 or 35) *vs* imatinib ($MR^{4.5}$; 42 or 47).
Summary/Conclusions: The superior efficacy of dasatinib over imatinib was shown in previous studies. Response rates and times to response were comparable in patients with 0 or ≥1 comorbidity and trended in favor of dasatinib *vs* imatinib. Although a few AEs (most grade 1/2) appeared to occur at a higher frequency in patients with ≥1 *vs* 0 comorbidities in either treatment arm, the overall incidence of AEs and discontinuation rates at 5 years in patients who were treated with first-line dasatinib or imatinib did not appear to be substantially affected by baseline comorbidities.

E1061

ADHERENCE TO SECOND LINE THERAPY WITH NILOTINIB AND QUALITY OF LIFE OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA: A MULTICENTER PROSPECTIVE OBSERVATIONAL STUDY

T. Sacha[1,*], J. Góra-Tybor[2], E. Wąsak-Szulkowska[3], S. Kyrcz-Krzemień[4], E. Mędraś[5], R. Becht[6], G. Bober[4], A. Kotowska[3], J. Wącław[1], A. Hellmann[7]
[1]Department of Hematology, Jagiellonian University, Kraków, [2]Department of Hematology, Institute of Hematology and Transfusion Medicine, [3]Hematology, Novartis-Poland, Warszawa, [4]Department of Hematology and Bone Marrow Transplantation, Silesian Medical University, Katowice, [5]Department of Hematology, Malignant Blood Diseases and Bone Marrow Transplantation, Wroclaw Medical University, Wrocław, [6]Department of Hematology, Pomeranian Medical University in Szczecin, Szczecin, [7]Department of Hematology and Transplantology, Gdańsk Medical University, Gdańsk, Poland

Background: Introduction of second-generation TKIs (2GTKIs) provided additional options to treat CML patients effectively. Patient compliance is crucial to achieve good outcomes of TKI therapy. The recommended dose of nilotinib – potent 2GTKI in a second-line treatment is 400mg twice daily. The drug's administration might be more challenging for patients as compared to other TKIs. Nilotinib should be taken twice daily approximately 12 hours apart, and must not be taken with food. No food should be consumed two hours before and at least one hour after the drug is administered. Recent studies comparing adherence to the second-line CML treatment with nilotinib and dasatinib reported conflicting results. It has been reported that the therapy with TKIs might have an adverse effect on the quality-of-life (QOL). To date the majority of the research on QOL among patients treated with TKIs has been focused on imatinib.
Aims: The aim of this study was to assess the adherence to nilotinib used as a second line therapy and to evaluate the quality-of-life (QOL) in patients with chronic myeloid leukemia in a chronic phase (CML-CP), as well as to analyze the correlation between QOL and drug compliance, the correlation between patient's and physician's assessment of drug compliance and to evaluate the relationship between drug compliance and dosing schedule (twice daily, once daily), patient's age, educational and marital status, satisfaction with medical care and the QOL.
Methods: The study was designed as a multicenter prospective observational trial. The enrollment period lasted from June 2010 to June 2012. The duration of the observation of an individual patient was 12 months. 177 patients were recruited in 23 centers in Poland and evaluated during the study at six time points. Nilotinib is not reimbursed in Poland as a first-line therapy. Therefore, eligible were patients suffering from CML-CP, treated with nilotinib as a second line therapy due to the ineffectiveness or intolerance of first line therapy. The adherence to the therapy was assessed using the 4-item Morisky Medication Adherence Scale (MMAS) and reported by patients and their physicians at 1, 3, 6, 9 months and at the completion of the observation. The QOL was evaluated with the standard Core Quality of Life (EORTC QLQ-C30) questionnaire. Basic descriptive statistics were used to present results of the study.
Results: 83.2% of patients assessed themselves as highly compliant at their first visit and 93.4% at the 5th visit. Males were less compliant to nilotinib than females. Patients who live with families were more compliant than those who live with a partner or live alone. Low compliant patients represented 1.7% of total during visit 1; none of the patients assessed themselves as low compliant since the 4th visit. At the first visit 85.3% of patients were categorized by their physicians as highly compliant and 96.0% during the last three visits. Patients and physicians assessments were significantly correlated. No significant differences in drug compliance in patients treated once daily *vs* twice daily were found in all groups of patients. The average QOL expressed as QL2 parameter in patients that have completed the study was significantly higher during the last visit (69.4±17.4) than at the start of the study (59.1±18.8; p<0.001).
Summary/Conclusions: The adherence to the treatment was high and the QOL among patients on nilotinib administered as a second-line therapy was very good. Both have been improved during the study. The efficacy and safety of the drug were confirmed in the real-life setting.

E1062

RADOTINIB TREATMENT IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WITH RESISTANCE OR INTOLERANCE TO BCR-ABL1 TKIS: 36 MONTHS UPDATE OF RADOTINIB PHASE 2 STUDY

S.-H. Kim[1,*], H. Menon[2], S. Jootar[3], T. Saikia[4], J.-Y. Kwak[5], J.S. Park[6], H.J. Kim[7], S.J. Oh[8], H. Kim[9], D.Y. Zang[10], S. Park[11], H.L. Park[12], G.Y. Lee[12], D.J. Cho[12], J.S. Shin[12], D.-W. Kim[13]

Co., Ltd, Yongin, [13]St. Mary's Hospital, The Catholic University of Korea, Cancer Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Radotinib is an orally active, selective BCR-ABL1 tyrosine kinase inhibitor (TKI), approved for the first-line and second-line treatment of chronic phase chronic myeloid leukemia (CP-CML) patients in Korea. Earlier 12 and 24 month results demonstrated that radotinib is effective and well tolerated in CP-CML patients with resistance and/or intolerance to BCR-ABL1 TKIs.
Aims: We update the long-term outcome of radotinib treatment in patients failed to BCR-ABL1 TKIs with a minimum follow-up of 36 months.
Methods: Ph^+ CP-CML patients who failed prior TKI therapy were enrolled between July 2009 and November 2011. All patients were treated with radotinib 400mg twice daily. Cytogenetic and molecular assays were performed at baseline, every 3 months, and at treatment failure. Safety parameters were also analyzed. Probabilities of overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier method.
Results: A total of 77 CP-CML patients (18 years of age or over) were enrolled. This analysis includes data from last enrolled patient who received at least 36 months of radotinib therapy. With a median follow-up of 45.7 (range 0.9-65.7) months, 31 patients (40.3%) completed 36 months treatment, and 46 patients (59.7%) discontinued the treatment before 36 months. Main reasons of discontinuation were abnormal laboratory test (n=18), adverse events (n=4), treatment failure including disease progression and lack of response (n=18), death (n=2), and other reasons (n=4). Median duration of radotinib exposure was 19.5 (0.3-60.9) months. Cumulative incidence of complete cytogenetic response (CCyR) by 36 months was 90.0% and of patients achieving CCyR, 45.0% (18/40) achieved MMR. The drug-related safety profiles were consistent with those previously reported and new safety issues have not been observed after 12 months. Most drug-related AEs have developed within 12 months, and have shown minimal increase compared with rates at 12 months follow-up. Estimated OS and PFS at 36 months were 87.6% and 85.7%, respectively.

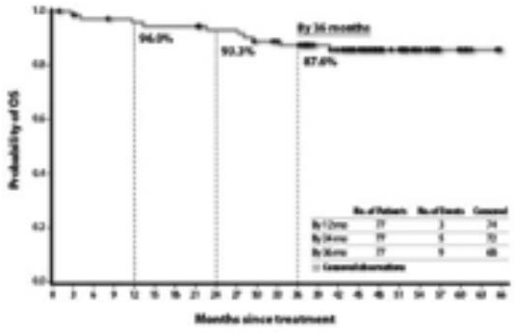

Figure 1.

Summary/Conclusions: The 36 months data supports radotinib treatment in TKI failed CML-CP patients maintains the effective response and high rates of OS & PFS rate. Thus, radotinib demonstrated a promising alternative treatment for patients with TKIs failure.

E1063

100 YEARS OF CHRONIC MYELOID LEUKEMIA PREVALENCE IN FRANCE

M. Delord[1,*]
[1]Biostatistics, Université Paris 7 - INSERM - UMR-S 717, PARIS, France

Background: The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70's, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems. The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70's, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.
Aims: We present here a fully detailed and comprehensive analysis of the French CML prevalence over a century from 1960 to 2060.
Methods: Prevalence of CML was estimated using a cohort component-based model fromestimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. Prevalence of CML was estimated using a cohort component-based model fromestimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. The number of CML patients is estimated over time and the resulting CML prevalence expressed as a number of CML patients per 100,000 inhabitants.
Results: The CML prevalence in France, expressed in cases per 100,000 inhabitants, was estimated to be around 3 before the 80's, 6 before the 2002, 17 in 2016, 25 in 2030 where the tendency inflects, and 30 after 2040. Considering the 100% relative survival hypothesis, a target CML prevalence were defined, the level of which will be nearly reached by 2060. By simulation, we showed that given constant incidence rates and high relative survival hypotheses, the CML prevalence will be driven by population aging, and that the target prevalence, defined as the maximum CML prevalence, should be nearly reached by 2050 to levels above 30 per 100,000 in-habitants. By simulation, we showed that given constant incidencerates and high relative survival hypotheses, the CML prevalence will be driven bypopulation aging, and that the target prevalence, defined as the maximum CMLprevalence, should be nearly reached by 2050 to levels above 30 per 100,000 inhabitants.

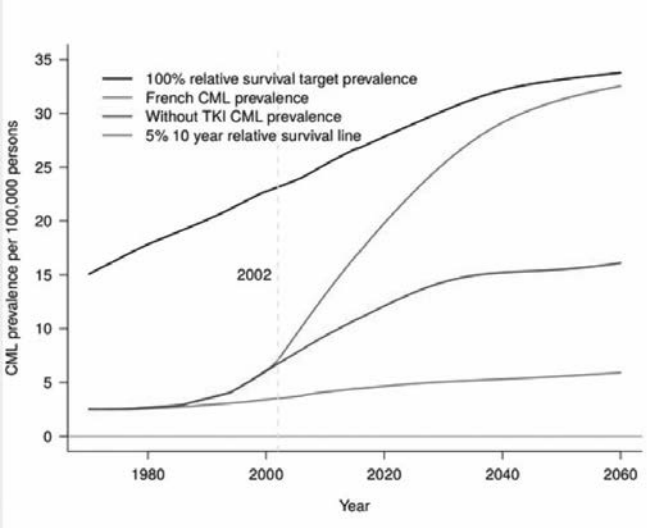

Figure 1.

Summary/Conclusions: Due to high rates of relative survival observed after introduction of imatinib, the trajectory of the CML prevalence in France, as in other western countries, has changed. Given particular hypothesis on the CML incidence rates, this trajectory will bring the CML prevalence by the mid century to levels fully determined by population aging. For France, we have estimated this level above 30 cases per 100,000 inhabitant. Due to high rates of relative survival observed after introduction ofimatinib, the trajectory of the CML prevalence in France, as in other westerncountries, has changed. Given particular hypothesis on the CML incidence rates,this trajectory will bring the CML prevalence by the mid century to levels fullydetermined by population aging. For France, we have estimated this level above30 cases per 100,000 inhabitant.

THE ROLE OF MICRORNAS IN CHRONIC MYELOID LEUKEMIA THERAPEUTIC SELECTION

R. Alves[1,2], A.C. Gonçalves[1,2], P. Couceiro[3], P. Rodrigues-Santos[2,3,4], P. Freitas-Tavares[5], L. Ribeiro[5], A. M. Almeida[6,7], A. B. Sarmento-Ribeiro[1,2,5,*]
[1]Applied Molecular Biology and University Clinic of Hematology, [2]CIMAGO, Faculty of Medicine University of Coimbra, [3]Immunology and Oncology Laboratory, Center for Neurosciences and Cell Biology (CNC), [4]Immunology Institute, Faculty of Medicine University of Coimbra, [5]Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, [6]Hematology Service, Instituto Português de Oncologia de Lisboa Francisco Gentil (IPOL), [7]CEDOC, Nova Medical School, Lisbon, Portugal

Background: Chronic myeloid leukemia (CML) is characterized by the presence of *BCR-ABL* fusion gene. This molecular event becomes the main therapeutic target with Imatinib as first-line treatment. In spite of the continued clinical success of Imatinib on CML treatment, the emergence of resistance to tyrosine kinase inhibitors (TKIs) had stimulated the research of the mechanisms involved. These included those related with target changing (e.g. the presence BCR-ABL gene mutations and amplifications) and with intracellular drug concentrations (e.g. the abnormal levels of influx and efflux transporters such as OCT1/OCNT2 and PgP/BCRP, respectively). MicroRNAs (miRNA) are important regulators of both mechanisms, and so, could influence TKIs response.
Aims: In this context, we investigated the role of miR-203, miR-21, miR-519c, miR-451 and miR-26 expression levels in TKI response in CML patients, and correlated them with TKI sensitivity, BCR-ABL levels, and disease progression, among other clinical and laboratory data.
Methods: To this end, we assessed the expression levels of miR-203, miR-21, miR-519c, miR-451, miR-26 and miR-16 (endogenous control) by TaqMan MicroRNA Assays in peripheral blood cells from 31 patients with CML at follow-up examinations. We also studied 4 CML cell lines, K562 a cell line sensitive to Imatinib, LAMA-84 a cell line with 4 copies of chromosome Philadelphia (Ph), and 2 Imatinib resistant cell lines models created in our lab (K562-RC and K562-RD). K562-RC cells, generated by continuous exposure to Imatinib, present an IC50 8x times higher than the parental cell line (K562); in K56-RD cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% ($p<0.05$).
Results: The miR-203 and miR-519c expression was not detected in any cell line or CML patient. First, we correlated miRs expression with *BCR-ABL* levels. Higher levels of tumor suppressor miR-451 were associated with a higher reduction of *BCR-ABL* levels (lower than 0.01%) in CML patients and patients with higher *BCR-ABL* present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RD comparing with sensitive cell line (K562; $p<0.05$). On the other hand, patients with more BCR-ABL content (between 1.0% and 0.1%) present higher expression of the oncomiRs, mir-21 and miR-26. These miRs were also up-regulated in resistant cell lines. MiR-21 was more relevant for K562-RC cells (4-fold higher than K562). LAMA-84 and K562-RD cell lines showed almost 2 times more expression of miR-26. Next we analyzed if treatment options affected miRs expression. CML patients under Imatinib treatment showed higher levels of miR-451 associated with less expression levels of miR-21 and miR-26. Imatinib had been described to be able to block the BCR-ABL negative feedback on miR-451, increasing miR function. Since miR-21 and miR-26 were also lower expressed, more PTEN is available to block PI3K-AKT-mTOR pathways, decreasing this survival signaling. Opposite profile was observed in patients that changed treatment to a second generation TKI suggesting a different effect of this TKI on microRNA expression.
Summary/Conclusions: Our preliminary results suggested the involvement of miRNAs in *BCR-ABL* levels regulation and in TKI response, supporting the search of a miRNAs TKI response profile that could predicts the response in CML patients. This information could act as powerful tool for the stratification and selection of the best therapeutic approach (lower toxicity and cost effective), contributing to higher survival rates and better quality of life in CML patients.

E1065

IMPACT OF ABCB1 AND ABCG2 POLYMORPHISMS ON RESPONSE TO IMATINIB AND 2G-TKIS THERAPY IN PATIENTS WITH CHRONIC PHASE CML

M. Tiribelli[1,*], S. Di Giusto[1], E. Toffoletti[1], D. Penna[1], D. Griguolo[1], G. Maccari[1], F. De Marchi[1], M. Medeot[1], R. Fanin[1], D. Damiani[1]
[1]Division of Hematology and BMT, Azienda Sanitaria Universitaria Integrata di Udine, Udine, Italy

Background: Overexpression of multidrug resistance proteins ABCB1 and ABCG2 confers resistance to anticancer drugs, including tyrosine kinase inhibitors (TKIs). Various ABCB1 and ABCG2 single nucleotide polymorphisms

(SNPs) affect the transporter activity, but their impact on clinical response to imatinib in chronic myeloid leukemia (CML) is discordant; even less is known on their role in patients treated with second generation (2G) TKIs dasatinib and nilotinib.

Aims: To investigate the role of the most common ABCB1 and ABCG2 genetic polymorphism in chronic phase CML patients treated with imatinib and 2G-TKIs.

Methods: We analysed four polymorphisms of ABCB1 (129T>C, 1236C>T, 2677G>T/A and 3435C>T) and two polymorphisms of ABCG2 (34G>A and 421C>A) in 196 CP-CML patients, of whom 139 treated with imatinib (114 in first line and 25 after interferon failure) and 57 treated with dasatinib or nilotinib (22 in first line and 35 after imatinib failure), We compared the rates of optimal response at 3 months (defined as BCR/ABL <10%), at 6 months (BCR/ABL<1%) and at 12 months (BCR/ABL<0.1%), progression-free survival (PFS) and time to treatment failure (TTF) according to the different protein genotypes. TTF was calculated from the start of therapy to any of the followings: progression to accelerated or blastic phase (ABP), death for any cause at any time, treatment discontinuation for primary or secondary resistance or intolerance. PFS was calculated from the start of TKI to ABP or death.

Results: A total of 196 patients with CP-CML (median age 57 years, range 21-84) were included in the analysis. Frequency of ABCB1 and ABCG2 SNPs expression is summarized in Table 1. Considering response to therapy, either in imatinib-treated patients and in those receiving a 2G-TKI, we did not find any significant difference in terms of optimal response at the various timepoints, TTF or PFS for ABCB1 C1236T, G2677T and C3435T and of ABCG2 G34A and C412A polymorphism, even if there was a trend for a worse PFS in the few patients (n=3) with 1236 allele A treated with imatinib. Conversely, we found a lower rate of optimal response at 3 (p=0.1), 6 (P=0.05) and 12 (p=0.2) months in imatinib-treated patients with TC genotype of ABCB1 T129 SNP, though the small number of patients (7) had probably and impact on statistical significance. However, TTF was shorter for ABCB1 129T>C patients, both receiving imatinib (P=0.05) and 2G-TKIs (P=0.07), and also PFS was significantly shorter in this cohort (P=0.003).

Table 1.

MDR protein	SNP	Genotype	Frequency
ABCB1	C1236T	CC	32%
		CT	49%
		TT	19%
	G2677T	GG	33%
		CT	46%
		TT	18%
		A	3%
	C3435T	CC	26%
		CT	50%
		TT	24%
	T129C	TT	94%
		TC	6%
		CC	-
ABCG2	G34A	GG	92%
		GA	8%
		AA	-
	C421A	CC	83%
		CA	15%
		AA	2%

Summary/Conclusions: With the limits of the low expression rates of some SNPs, our data suggest a lower response in patients harboring 129T>C polymorphism, at least in those receiving imatinib. Other ABCB1 and ABCG2 genotypes do not seem to impact on response to TKI treatment.

E1066

THE INTRODUCTION OF SECOND-GENERATION TYROSINE KINASE INHIBITORS MAY REDUCE THE PROGNOSTIC IMPACT OF HIGH-RISK PATIENTS ACCORDING TO EUROPEAN TREATMENT AND OUTCOME STUDY (EUTOS) SCORE

E. Sato[1,*], N. Iriyama[2], M. Tokuhira[3], T. Takaku[4], M. Ishikawa[5], T. Nakazato[6], K.-J. Sugimoto[7], H. Fujita[8], I. Fujioka[4], Y. Hatta[2], M. Kizaki[3], N. Komatsu[4], N. Asou[5], T. Kawaguchi[9]

[1]Department of Hematology, Juntendo University School of Medicine Nerima Hospital, [2]Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Tokyo, [3]Department of Hematology, Saitama Medical Center, Saitama Medical University, Saitama, [4]Department of Hematology, Juntendo University School of Medicine, Tokyo, [5]Department of Hemato-Oncology, Saitama Medical University International Medical Center, Saitama, [6]Department of Hematology, Yokohama Municipal Citizen's Hospital, Yokohama, [7]Department of Hematology, Juntendo University Urayasu Hospital, Urayasu, [8]Department of Hematology, Saiseikai Yokohama Nanbu Hospital, Yokohama, [9]Department of Hematology and Infectious Diseases, Kumamoto University Hospital, Kumamoto, Japan

Background: The discovery of tyrosine kinase inhibitor (TKI) imatinib has revolutionized the conception of chronic myeloid leukemia (CML) as a mortal disease to a long-term controllable disease. The European Treatment and Outcome Study (EUTOS) score is a clinical tool that utilizes imatinib-based objectives to predict treatment response and progression free survival (PFS) in patients with CML in chronic phase (CP). However, it is currently unknown whether the introduction of second generation TKIs (2nd TKIs) affects prognostic score of patients with CML-CP, particularly among those considered high-risk according to EUTOS score.

Aims: Our study aims to highlight the critical role of the introduction of 2nd TKIs on patient prognosis as determined by EUTOS score.

Methods: Patients data was obtained retrospectively from patients enrolled in the CML Cooperative Study Group. Patients with CML-CP who were treated with any TKIs as first line therapy between April 2001 and January 2016 were enrolled to the study and were classified according to date of diagnosis. Those who were diagnosed with CML-CP before March 2009 were classified into the imatinib group, and those diagnosed after April 2009 were classified into the 2nd TKI group, as these patients were able to be treated with 2nd TKIs. The study was approved by the research ethics boards of each institution and was conducted in accordance with the Declaration of Helsinki.

Results: There were 308 patients newly diagnosed with CML-CP during the study period. Of these patients, 104 (34%) were assigned to the imatinib group and 204 (67%) were assigned to the 2nd TKI group. With respect to EUTOS score, 223 patients were classified as low-risk, of which 69 were in the imatinib group and 154 were in the 2nd TKI group. Forty-six patients were considered high-risk, of which 19 were in the imatinib group and 27 were in the 2nd TKI group. EUTOS score was unavailable in 39 patients. With regard to initial TKI, all patients were treated with imatinib in the imatinib group. Among patients assigned to the 2nd TKI group, 149 (73%) were initially treated with any TKI. The median follow-up period for all patients was 48 months (range: 1–185 months). Among patients in the 2nd TKI group, CML-associated death rates were significantly lower than those in the imatinib group. EUTOS high-risk patients score exhibited significantly worse outcomes in EFS, PFS, and CML-associated death compared to those considered low-risk. Most importantly, risk stratification by EUTOS score was predictive of risk-associated clinical outcomes in patients assigned to the imatinib group; however, EUTOS score failed to predict risk-associated clinical outcomes of patients assigned to the 2nd TKI group (see Figure). The EUTOS high-risk patients in the imatinib group showed worse clinical outcomes than those in the 2nd TKI group (hazard ratio [HR] 6.35, 95% confidence interval [CI] 1.79 – 22.6, *p*=0.0042). However, prognostic effect was less in the 2nd TKI group (HR 3.21, 95% CI 0.59 – 17.6, *p*=0.18). Out of 308 patients, 9 progressed to AP/BP, of which 8 transformed during imatinib therapy and 1 transformed during dasatinib therapy.

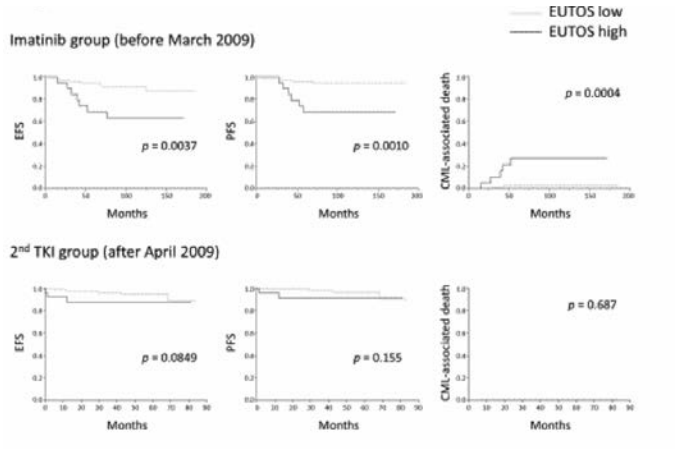

Figure 1.

Summary/Conclusions: Among patients assigned to the imatinib group, risk stratification by EUTOS score was predictive of clinical outcomes in that those considered high-risk experienced considerably more adverse events (EFS, PFS, or CML-associated death) than those considered low-risk. Our results support the use of 2nd TKIs in treating high-risk patients with CML-CP in order to avoid disease progression. Future large-scale studies are necessary to evaluate the clinical significance of EUTOS scoring in the accurate prediction of prognosis among patients with CML-CP treated with 2nd TKIs.

Eugenio Hospital, Tor Vergata Univetrsity, Rome, Italy, [3]Department of Hematology, Seoul St. Mary's Hospital, [4]Leukemia Research Institute, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of, [5]Hematology Department, SI "Institute of Blood Pathology and Transfusion Medicine UAMS", Lviv, Ukraine, [6]Research Institute of Hematology and Blood Transfusion MOH of Uzbekistan, Tashkent, Uzbekistan, [7]Hematology Center after prof. R.H. Yeolyan, Yerevan, Armenia, [8]FSBI Scientific Center of Obstetrics, Gynecology and Perinatology of Healthcare Ministry named after V.I. Kulakov, Moscow, Russian Federation

Background: Chronic myeloid leukemia (CML) diagnosed at pregnancy is a serious challenge. Treatment by tyrosine kinase inhibitors (TKI) today is considered harmful for fetus due to possible teratogenicity. On the other hand TKI delay is dangerous for disease progression as no other options have comparable to TKI effectiveness. Pregnancy termination by abortion may be crucial for desired pregnancies as further childbirth is postponed for years until stable deep molecular response (DMR). Due to limited number of cases and ethical issues there is no consensus on how to behave in such delicate cases.
Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.
Methods: Information regarding CML diagnosed at pregnancy was collected within the database of countries participating in the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytogenetic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

Table 1.

Table 1. Number of pregnancy cases in CML by countries and outcomes of pregnancies diagnosed simultaneously with CML

Country	number of CML females with pregnancies in database	number of pregnancy cases (including subsequent) in CML females	number of CML females diagnosed at pregnancy	Outcomes of 31 pregnancies diagnosed simultaneously with CML			
				Induced abortion	Spontaneu os abortion	Labor	Ongoing pregnancy
Russian Federation	98	135	21	7	1	11	2
Italy	ND*	100	2	2	-	-	-
Uzbekistan	16	19	3	-	-	3	-
South Korea	9	12	1	-	-	1	-
Ukraine	8	13	4	1	-	3	-
Armenia	2	3	-	-	-	-	-
Total number	133 (not counting Italian)	282	31	10	1	18	2

*the data are in progress of database input

Results: Thirty one women with median age 26 years (range 20-39) were diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML and pregnancy had the synchronistic onset of these events (table 1). Sokal low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2 patients correspondingly, no data for risk score was in 1 patient. CML was diagnosed in 1st/2nd/3rd trimester in 18/7/6 females correspondingly. Induced abortion was done before CML therapy was started in 10 (32%) around 10 obstetrician week (range 6-17), spontaneous abortion happened in 1 woman (at week 8th). Pregnancy was prolonged by consistent desire or religious reasons in 20 females: 2 pregnancies are ongoing now and 18 have ended in childbirth. No treatment till labor was in 5 women. Treatment of CML during pregnancy was initiated in 15 of 20 patients. Interferon alpha (IFN) was given to 5 women and 3 of them were switched to imatinib (IM) 400mg daily in 2nd-3rd trimester due to insufficient control of complete blood count. IM 400mg daily in 1st line was also taken by 9 women since 2nd-3rd trimester. In summary 12 women got IM from Me 22nd week (range 16-36). One woman got hydroxyurea (HU) from 3rd trimester till labor and 3 got HU shortly for 5-7 days before any other treatment in 1st-2nd trimester. Nineteen healthy newborns (including twins in 1 case) were born: 14 at term, 5 by preterm delivery at week 35-37. There were no birth abnormalities in 10 newborns exposured to IM in 2nd-3rd trimester. Two pregnancies under IM exposure are currently at week 17 and 31, developing normally. Four infants had low birth weight (<2500 g): 3 of them were exposed to IM and 1 for HU at pregnancy. Follow-up of children was uneventful with Me observation time 47 months (range 9-192) and Me observation time 38 months (range 9-63) for 10 infants exposed to IM in 2nd-3rd trimester. Twenty nine of 31 women with CML diagnosed at pregnancy are alive and continue TKI treatment, 2 women unfortunately died: 1 patient with postponed switch from IFN to IM during pregnancy progressed to blast crisis after labor and had furher bone marrow transplant failure while 1 patient after induced abortion developed rapid blast crisis with *BCR-ABL* compound mutations including T315I.
Summary/Conclusions: This is the first report of a large database of women diagnosed with CML during pregnancy. Management of this very delicate subset of patients is a challenge especially when a woman refuses from abortion. Individual treatment approach may differ considering pregnancy terms and clinical status. Although normal childbirth is possible using IM after 2nd-3rd trimester, the risks of pregnancy prolongation remain still not well defined. To get the most safe prognosis for mother and child pregnancy in CML should be planned in a stable DMR.

E1068

IMPACT OF KIR3DL1*00501 IN TYROSINE KINASE INHIBITOR-TREATED CML

H. Ureshino[1,*], T. Shindo[2], Y. Kusunoki[3], Y. Miyazaki[3], H. Kojima[3], H. Tanaka[3], H. Saji[3], A. Kawaguchi[4], S. Kimura[1]
[1]Div. Hematology, respiratory medicine and oncology, Japan, Saga University, Saga city, [2]Dep.Hematology and Oncology, Kyoto University, [3]HLA Foundation, Kyoto, [4]Center for Comprehensive Community Medicine, Japan, Saga University, Saga city, Japan

Background: The BCR-ABL1 tyrosine kinase inhibitors (TKIs) dramatically improved long-term survival of the patients with chronic myeloid leukemia (CML). As increased NK cells during TKI therapy positively correlate with better outcome, antitumor immunity by NK cells may contribute to the effects of TKIs. However, the response to TKIs depends on each case, and the determinants of it remain to be elucidated.
Aims: Given that NK cell function is regulated depending on the interaction between killer immunoglobulin-like receptor (KIR) and human leukocyte antigen (HLA) class I molecules, we hypothesized that polymorphisms of KIR and HLA play important roles on the responses to TKIs. Then we performed allele genotyping of KIR and HLA with deep sequencing in CML patients, and here report their clinical impacts.
Methods: KIR and HLA high resolution typing were performed on peripheral blood DNA from 76 CML patients in chronic phase (CML-CP) using Scisco Genetics typing kit (Scisco Genetics Inc., Seattle WA) and MiSeq as platform by NGS. Therapeutic effects of TKIs were evaluated based on *bcr-abl* mRNA levels measured by real-time quantitative (RQ)-PCR compensated according to international scale (IS) and/or transcription mediated amplification (TMA) method. Major molecular response (MMR) was defined as 3-log reduction (MR^3) in RQ-PCR (IS) or BCR-ABL transcript level of less than 50 copy/0.5 μg RNA in TMA method. We also defined DMR as 4-log reduction ($MR^{4.0}$) in RQ-PCR (IS), which is similar to undetectable of BCR-ABL transcript level in TMA method. The Cox proportional hazards model was used in the time-to-event analysis. A p value<0.05 was considered statistically significant.
Results: Second generation TKIs as first-line therapy (n=46) and female (n=29) sex were strongly associated with superior DMR at the 2-year of therapy (second generation TKIs as first-line treatment, HR 7.305, 95% CI, 3.377 to 15.803; p<0.001; female sex, HR, 1.709; 95% CI, 1.028 to 2.842; p=0.039). After adjustment with these two factors, several KIR alleles positively correlates with superior DMR at the 2-year; KIR2DL4*008 or 011/00501 (HR 1.942, 95%CI 1.160 to 3.250, p=0.012); KIR2DS4*00301 or 007/010 or 015 (HR 2.811, 95% CI, 1.590 to 4.968, p<0.001); KIR3DL1*00501 (HR 3.634, 95% CI 1.884 to 7.013, p<0.001). Interestingly, KIR3DL1*00501 for the patients has more strong linkage to KIR2DL4*008 or 011/00501, and 2DS4*00301 or 007/010 or 015 than other KIR3DL1 alleles. (Fisher's exact test, p<0.001).
Summary/Conclusions: KIR3DL1*00501 and several KIR2DL4 and 2DS4 alleles positively correlate with better therapeutic effects of TKIs, and they may be form the same KIR haplotype. Our data indicate that these KIR alleles represent strong anti-CML immunity by NK cells, and consequently may associate with long-term outcome and treatment-free remission in CML.

of Ulsan college of Medicine, Ulsan, [9]School of Medicine, Keimyung University, Daegu, [10]Chonbuk National University Medical School, Jeonju, [11]St. Vincent's Hospital, The Catholic University of Korea, Suwon, [12]Asan Medical Center, University of Ulsan College of Medicine, [13]School of Medicine, Ewha Womans University, Seoul, [14]Inje University College of Medicine, Inje University Busan Paik Hospital, Busan, [15]National Health Insurance Service Ilsan Hospital, Ilsan, [16]Gachon University Gil Hospital, Incheon, [17]Chungbuk National University Hospital, Cheongju, Korea, Republic Of

Background: Recent reports have demonstrated that tyrosine kinase inhibitors (TKIs) discontinuation can be employed in chronic phase chronic myeloid leukemia (CP CML) patients with sustained deep molecular responses after enough TKI therapy. Consequently, treatment-free remission (TFR) has been a new therapeutic goal. Although 50-70% of patients experienced molecular relapse by several imatinib (IM) discontinuation studies, the most of patients resumed molecular responses (MR) following restart of IM.
Aims: Though the Korean multicenter prospective study (Korean Imatinib Discontinuation Study; KID Study), we have explored molecular kinetics after the first IM discontinuation and after IM resumption for molecular relapse. In patients regaining durable UMRD with IM resumption, we tried second IM discontinuation and compared molecular kinetics between the first IM stop and second IM stop.
Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction (PCR) for at least 2 years were eligible for KID study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, the molecular response was evaluated every month until MMR was re-achieved and every 3 months thereafter. The second stop was permitted in the patients who were in second UMRD for at least 2 years.
Results: Among patients who lost MMR in 2 consecutive analyses and resumed IM in the KID study, 12 patients (6 men and 6 women) with a median age of 45 years (range, 25-59 years) entered into a second IM discontinuation after maintaining UMRD at least 2 years. Prior to first discontinuation, the median duration of IM therapy was 68.9 months (range, 38.5-115.1 months) and the duration of sustained UMRD was 32.9 months (range, 24.8-64.5 months). After first attempt of IM discontinuation, they relapsed after a median duration of 3.7 months (range, 1.8-13.1 months) and re-achieved UMRD at a median of 6.7 months (range, 3.3-13.6 months) after IM resumption. After sustaining a second UMRD for a median of 25.5 months, IM therapy discontinued for a second time. After a median follow-up of 8.8 months (range, 0.3-38.1 months) after second IM discontinuation, 10/12 patients (83%) and 8/12 patients (67%) lost UMRD and MMR, respectively. Among two patients who lost UMRD but not MMR, one patient showed fluctuation of *BCR-ABL1* transcript under the level of 0.1% on IS for 9.4 months and another patient have shown gradually increasing BCR-ABL1 transcripts under the level of 0.1%. Eight patients who experienced second relapse (MMR loss) after a median 2.9 months (range, 1.9-30.7 months). The patients who lost MMR, except one patient, were retreated with IM for a median of 7.1 months (range, 0.8-24.8 months); five patients re-achieved MMR at a median of 1.8 months (range, 1.0-10.2 months) and one re-achieved UMRD at 5.5 months.
Summary/Conclusions: Our data demonstrated that a second attempt might be possible and the median time to MMR loss after second discontinuation was similar to those of the first discontinuation. But the molecular kinetics after second IM resumption needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.

Background: BCR-ABL1 transcripts ≤1% after 6 months was an effective predictor. Also, radotinib showed that optimal molecular responses at landmark time point 3, 6, and 12 month were significantly higher than imatinib group.
Aims: We evaluated the impact of molecular response by 24 months for molecular level after 3 months (BCR-ABL1 transcript level ≤10%) and 6 months (BCR-ABL1 transcript level ≤1%) of radotinib 300mg twice daily (bid) approved for first-line use in Korea or imatinib treatment in newly diagnosed CML-CP.
Methods: Based on baseline demographics and Sokal risk score, 241 patients were randomized 1:1:1 to radotinib 300mg bid (n=79), radotinib 400mg bid (n=81), or imatinib 400mg once daily (qd) (n=81). 157 patients with available 3 months qRT-PCR on study therapy [radotinib 300mg bid (n=79), and imatinib 400mg qd (n=78)] were evaluated. And, total of 151 patients who received radotinib 300mg bid (n=77), and imatinib 400mg qd (n=74) were evaluable at 6 months. Molecular response was assessed by RQ-PCR at baseline and every 3 months. BCR-ABL1 transcript level was measured by RQ-PCR, standardized according to international scale (BCR-ABL^{IS}). Major molecular response (MMR) was defined by BCR-ABL1/ABL1 ratio ≤0.1%^{IS} and MR$^{4.5}$ was defined as ≥4.5 log reduction in BCR-ABL1 transcript levels from standardized baseline or BCR-ABL1/ABL1 ratio ≤0.0032%^{IS}.
Results: In two study groups, early molecular response (EMR) at 3 months were observed in 86.1% of patients in the radotinib 300mg bid group and 67.9% in the imatinib group *(P=0.0179)*. More patients treated with radotinib 300mg bid who had EMR at 3 months achieved MMR and MR$^{4.5}$ by 24 months: 73.5% and 38.2% in the radotinib 300mg bid group and 63.6% and 29.1% in the imatinib group, respectively. At 6 months, 73.4% of patients in the radotinib 300mg and 53.1% patients in imatinib group (*P=0.0246*) achieved 6 months EMR. The patients who had EMR at 6 months in radotinib 300mg bid group were significantly higher MMR and MR$^{4.5}$ compared with the patients who were not achieved EMR (*P<0.0001*), which they achieved MMR and MR$^{4.5}$ by 24 months: 86.2% and 44.8%, respectively and imatinib group achieved 81.4% and 39.5%, respectively. By 24 months, overall survival (OS) and progression-free survival (PFS) according to 3 months or 6 months were not significantly different in two groups.
Summary/Conclusions: With minimum 24 months follow-up, early responses at 3 months or 6 months can predict better outcomes in newly diagnosed chronic myeloid leukemia patients treated with radotinib or imatinib. But, to evaluate the significant long-term prognostic value such as overall survival and progression-free survival by EMR, longer follow-up are needed.

E1071

HYDROXYUREA SUPPRESSES BCR-ABL1 T315I+ CML CLONES *IN VIVO* AND *IN VITRO* AND SYNERGIZES WITH PONATINIB IN ELIMINATING TKI-RESISTANT CML CELLS

M. Schneeweiss[1,2,*], K. Byrgazov[3], S. Preuner[3], S. Herndlhofer[1,2], W.R. Sperr[1,2], G. Hoermann[4], M. Deininger[5], T. Lion[3], P. Valent[1,2], K.V. Gleixner[1,2]
[1]Ludwig Boltzmann Cluster Oncology, [2]Department of Internal Medicine I/Division of Hematology and Hemostaseology, Medical University of Vienna, [3]Children's Cancer Research Institute (CCRI), [4]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria, [5]Department of Internal Medicine/Division of Hematology and Hematologic Malignancies, University of Utah, Salt Lake City, United States

Background: In chronic myeloid leukemia (CML), *BCR-ABL1*^{T315I} leads to resistance against most BCR-ABL1 tyrosine kinase inhibitors (TKI). Long-term therapy with ponatinib, which suppresses BCR-ABL1^{T315I}, is problematic because of side effects. In addition, resistance against ponatinib may develop due to occurrence of compound mutations in *BCR-ABL1*. Therefore, alternative therapies have to be considered. Hydroxyurea (HU) has been used for (palliative) treatment of CML over decades. However, the effects of HU on TKI-resistant sub-clones have not been examined so far.
Aims: The aim of this study was to evaluate the effects of HU on CML subclones carrying *BCR-ABL1*^{T315I} mutations (isolated or in compound-configuration) *in vitro* and *in vivo* and to explore cooperative effects between HU and ponatinib.
Methods: Four *BCR-ABL1*^{T315I}+ CML patients were treated with HU (1-3 g/day) for 2 to 18 months. White blood counts (WBC), differential counts, and *BCR-ABL1* transcript levels were reported. The *BCR-ABL1*^{T315I}/*BCR-ABL1* ratio was determined by mutation-specific, ligation-dependent, PCR and next generation sequencing. In *in vitro* studies, primary CML cells, the CML cell lines K562, KU812, KCL-22, and KCL-22^{T315I} as well as Ba/F3 cells expressing *BCR-ABL1*^{WT} (Ba/F3p210^{WT}), or mutant *BCR-ABL1* (Ba/F3p210^{T315I}, Ba/F3p210$^{T315I/E255K}$, Ba/F3p210$^{T315I/F311L}$, Ba/F3p210$^{T315I/F359V}$, Ba/F3p210$^{T315I/G250E}$) were examined. Cell proliferation was quantified by ^{3}H-thymidine uptake. Apoptosis was determined by flow cytometry. Drug effects on competitive clonal growth were analyzed by mixing Ba/F3p210^{WT} (labeled with GFP) with Ba/F3p210$^{T315I/F359V}$ or Ba/F3p210$^{T315I/E255V}$ (labeled with tdTomato) at a ratio of 1:1. Then, cells were exposed to HU, pontinib, or

HU+ponatinib for 72 hours, and the percentage of viable cells in each sub-clone was analyzed by flow cytometry.
Results: HU treatment resulted in WBC stabilization in 3 of 4 patients, but failed to induce a molecular response. However, surprisingly, the percentage of *BCR-ABL1*^{T315I}decreased significantly in all 4 patients during HU treatment and was no longer detectable in 3 of 4 cases. Stem cell transplantation could be performed in 2 patients after 2-3 months. In one patient, stable disease over 18 months was obtained with HU-therapy. In one patient, the disease progressed rapidly despite temporary suppression of *BCR-ABL1*^{T315I}. In *in vitro* studies, HU was found to block the growth in all cell lines tested and in all primary cell samples (n=7) examined, with IC_{50} values ranging between 50 and 250 μM. Interestingly, cell lines exhibiting mutant *BCR-ABL1* were more sensitive against HU than cell lines expressing *BCR-ABL1*^{WT}. HU and ponatinib were found to synergize in inhibiting growth of all cell lines tested, including cells expressing *BCR-ABL1*^{T315I} or T315I-including compound mutations. Cooperative drug effects were also confirmed in primary CML cells (n=4). In cell mixing experiments, ponatinib was found to supress Ba/F3p210^{WT} cells but not Ba/F3p210$^{T315I/F359V}$ or Ba/F3p210$^{T315I/E255V}$ cells, whereas HU was found to exert stronger effects on cells expressing mutant *BCR-ABL1*, and the drug combination resulted in complete suppression of all sub-clones.
Summary/Conclusions: Our data show that HU exerts strong, sub-clone specific, anti-neoplastic effects in TKI-resistant CML cells *in vivo* and *in vitro*. In addition, HU and ponatinib produce synergistic growth-inhibitory effects on TKI resistant CML cells. Clinical studies are now warranted to define the exact value of the drug combination ponatinib+HU in TKI resistant CML.

ASSOCIATION OF BCL2L11 (BIM) DELETION POLYMORPHISM WITH MOLECULAR RELAPSE AFTER TYROSINE KINASE INHIBITOR CESSATION IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH DEEP MOLECULAR RESPONSE

S. Katagiri[1,*], T. Tauchi[1], Y. Tanaka[1], K. Ando[1], S. Okabe[1], M. Gotoh[1], Y. Ito[1], T. Umezu[12], K. Tadokoro[3], J.H. Ohyashiki[2], K. Ohyashiki[1]
[1]Department of Hematology, [2]Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, [3]BML, INC, Saitama, Japan

Background: The inhibition of BCR-ABL1 kinase with tyrosine kinase inhibitors (TKIs) has markedly improved the prognosis of chronic myeloid leukemia (CML). Recently, it has been recognized that some CML patients with deep molecular response (DMR) can maintain treatment-free remission (TFR) after TKI cessation. However, no predictive prognostic factor for successful treatment cessation has yet been identified. *BCL2L11 (BIM)* deletion polymorphism (intron 2) has been reported to be associated with an inferior response to TKI (Ng *et al.* Nature Medicine, 2012). We have previously reported that *BIM* deletion polymorphism may predict relapse after TKI discontinuation (Katagiri *et al.* Br J Haematol, 2013).
Aims: To further clarify the role of predictive biomarkers in molecular relapse after TKI cessation, we performed a long-term follow-up of CML patients with DMR after TKI cessation.
Methods: Patients with DMR receiving TKI treatment were included. Molecular relapse was defined as a loss of the major molecular response (MMR). The genomic DNA of patients was obtained from their whole blood samples using the EZ1 DNA Blood 350 l kit (Qiagen, Valencia, USA). Deletion polymorphism was detected by Q-Invader assay using primers designed to detect a deletion site (2,903 bp) (Ohyashiki *et al.* J Hematol Transfus, 2014).
Results: Forty-six CML patients (29 men;17 women; median age, 58.5 years) were included in this study (Sokal category; low: 32, intermediate: 10, and high: 2). Thirty-three patients discontinued imatinib, five discontinued nilotinib, and eight discontinued dasatinib. Ten patients were treated with IFNα before TKI treatment. The median duration from TKI initiation to cessation was 85.0 (range: 22–177) months; the median duration of DMR before TKI cessation was 43.0 (range: 5–131) months. Treatment-free remission was estimated to be 66.5% at 12 months, 61.5% at 24 months, and 58.5% at 36 months. Thirty-six CML patients were analyzed for the presence of *BIM* deletion polymorphism of which six exhibited *BIM* deletion polymorphism. All patients with *BIM* deletion polymorphism relapsed within 12 months after TKI cessation. A significant difference was observed only in *BIM* deletion polymorphism between the patients who maintained and those who lost MMR (p=0.0000528). No patient died during the follow-up period. No significant difference was observed in the second TKI therapy, prior IFNα therapy, and time to DMR between relapsing and non-relapsing patients.
Summary/Conclusions: The analysis of *BIM* deletion polymorphism in CML patients is expected to be useful for predicting their early molecular relapse after TKI treatment discontinuation.

[1]EFS BFC, Inserm UMR1098, University hospital Besancon,, University Franche Comte, Besancon, France, [2]Oncology, R&D, Cepheid, Sunnyvale, [3]Department of Laboratory Medicine, University of Washington, Seattle, [4]School of Medicine, Washington University, Saint Louis, [5]Karmanos Cancer Institute, Wayne State University, [6]Department of Pathology, Wayne State University School of Medicine and Detroit Medical Center University Laboratory, Detroit, [7]Molecular Pathology Laboratory, University of Iowa Carver College of Medicine, Iowa City, [8]Department of Pathology & Laboratory Medicine, Medical University of South Carolina, Charleston, [9]Division of Hematology, Department of Internal Medicine, The Ohio State University, Columbus, [10]Data Management and Analytics, [11]Medical and Scientific Affairs and Strategy, Cepheid, Sunnyvale, United States

Background: The ability to consistently detect low levels of BCR-ABL transcripts in patients with chronic myeloid leukemia (CML) is important in the assessment of treatment outcomes in patients on tyrosine kinase inhibitor (TKI) therapy. Particularly, BCR-ABL assays that are sensitive in the measurement of deep level response may aid in the identification of potential candidates for treatment discontinuation. Xpert® BCR-ABL Ultra detects the most common BCR-ABL transcripts below MR$^{4.5}$ (Molecular Response at 4.5-log reduction) or 0.0032%, which is widely accepted as the clinical threshold that defines candidates who can safely discontinue TKI therapy.
Aims: The present studies were designed to verify the limit of detection (LoD) for the Xpert® BCR-ABL Ultra assay below MR$^{4.5}$ on the international Scale (*IS*) in clinical samples for both the b3a2 and b2a2 transcripts.
Methods: To overcome the challenge of testing numerous replicates requiring large volumes of patient samples,, serial dilutions ranging from BCR-ABL/ABL levels of 10% to <0.001% (*IS*) were prepared as contrived samples using CML patient blood with initial BCR-ABL level >10% (*IS*) and pooled blood from CML negative patients, ranged from 10% to <0.001% (*IS*). Twenty-one replicates of each dilution were measured for%BCR-ABL/ABL (*IS*). Determination of the LoD was performed by the statistical analysis to identify the lowest concentration of%BCR-ABL/ABL (*IS*) per test that can be reproducibly distinguished from negative samples with 95% confidence. The acceptable precision for%BCR-ABL/ABL (*IS*) is defined as the ability to detect at least a 3-fold difference for all concentrations tested.
In addition, analytical LoD studies were performed using spike-in CML cell lines and cell-line derived RNAs, carrying either b3a2 or b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low BCR-ABL transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (*IS*)] with reporting below 0.05% (*IS*).
Results: Consistent results were observed in the both the diluted CML patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR$^{4.5}$ and below with a less than 2-fold difference at the LoD levels. With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (*IS*) (SD=~0.17 Log) to 0.0011% (*IS*) (SD=~0.4 Log). The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of ≥32,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.
Summary/Conclusions: These LoD evaluations demonstrate that the Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR$^{4.5}$ with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.

Background: Gaucher disease (GD) varies greatly in severity and organ involvement. Clinical characteristics are usually nonspecific and lead to late diagnosis with irreversible complications. Splenomegaly and thrombocytopenia are the two most common manifestations (Gaucher Registry, 2008), which reported 86% cases with moderate to severe splenomegaly and 60% thrombocytopenia at the time of diagnosis, thus demonstrating why patients are referred to hematology. A diagnosis of GD is considered after other diagnostic hypotheses have been ruled out. The consensus of international experts on the management of patients with GD established a diagnostic algorithm that is particularly intended for specialists (Mistry, 2010). Straightforward implementation of diagnostic algorithms to support medical specialties in Latin America for early diagnostic testing of GD is required.
Aims: To identify new cases of GD in a selected population with splenomegaly and/or thrombocytopenia referred to Hematology, Pediatric Hematology, Pediatrics, Genetics and Internal Medicine, using a selection algorithm for the general population (Mistry, 2010).

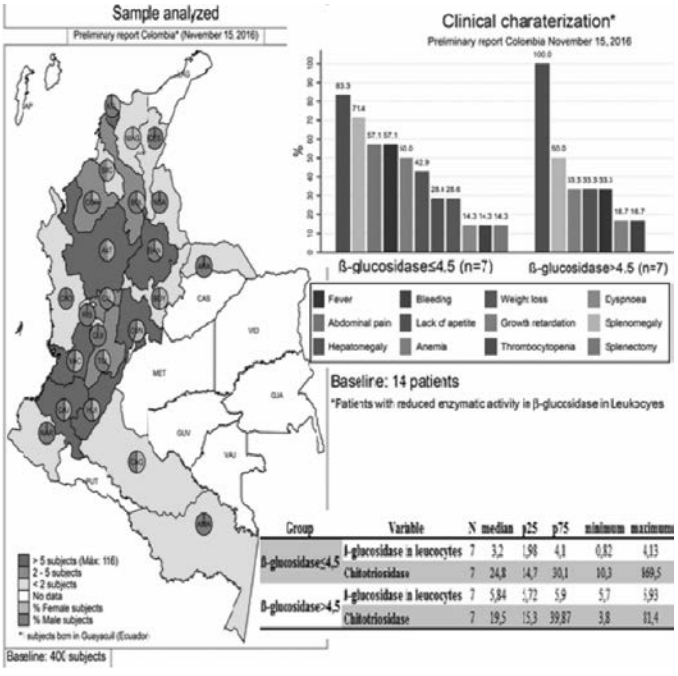

Figure 1.

Methods: Multicenter, descriptive study, in active recruitment process with non-probabilistic sampling by convenience. Currently, the study has 51 specialized medical centers in Hematology, Pediatrics and Internal Medicine in Colombia, approved by Ethics Committee (EC). The study has an expected duration of 24 months since EC approval for each center. Eligible subjects are those with three documented criteria: thrombocytopenia <150,000/cc plus anemia (hemoglobin <12g/dL in men and <11 g/dL in women) plus/or bone pain plus/or Monoclonal Gammapathy of Unknown Significance plus/or Polyclonal Gammapathy in subjects aged 30 years and older; and/or splenomegaly defined as palpable spleen ≥1cm below the costal rib or diagnosed by imaging, and/or Splenectomy by splenomegaly with no known cause. Subjects with prior diagnosis of GD, splenomegaly due to portal hypertension, hematologic malignancy, hemolytic anemia and thalassemia were excluded. Informed consent was obtained for all included subjects. Clinical information was collected from their medical history. The enzymatic activity of the β-glucocerebrosidase was performed in peripheral blood, using dried blood spots (DBS) and/or leukocytes. In subjects with reduced enzymatic activity in DBS, confirmatory β-glucocerebrosidase enzymatic activity in leucocytes was determined. GBA1 gene was analyzed.
Results: Since Feb/14 to Nov/16, 400 subjects have been included (51.3% men) with a median age of 28.79 years (range, 0.01 to 91.67). Reduced enzymatic activity of β-glucocerebrosidase was identified in 14 subjects (50% women) with a median age of 12.68 years (range, 0.9 to 74.85). All subjects were non-Ashkenazi origin, with 82.8% thrombocytopenia, 49.5% splenomegaly and 4.33% splenectomy. Detailed population description is on Figure 1.
Summary/Conclusions: This study suggests that selection algorithm could be implemented in Colombia, supporting specialists in making decisions on diagnosis of Gaucher Disease. Further characterization of the population is ongoing.

Acknowledgements: This study was funded by Sanofi Genzyme Colombia and coordinated by Caimed Colombia.

IMPACT OF PEROXIREDOXIN 2, GLUTATHIONE PEROXIDASE AND CATALASE INHIBITION ON OXIDATIVE STRESS MODIFICATIONS OF RED BLOOD CELL MEMBRANE AND CYTOSOL

D. Melo[1], S. Ribeiro[2], A. Santos-Silva[2], S. Rocha[2,*]
[1]Faculdade de Ciências, Universidade do Porto, [2]UCIBIO, REQUIMTE, Laboratório de Bioquímica, Departamento de Ciências Biológicas, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, Porto, Portugal

Background: Several anemias are associated with oxidative stress, namely, sickle cell anemia, β-thalassemia, glucose-6-phosphate dehydrogenase deficiency and hereditary spherocytosis. Red blood cells (RBC) are continuously exposed to oxidative stress, mainly due to their primary function as oxygen carriers; therefore, the erythrocytes are equipped with an efficient antioxidant system, however, when its capacity is overwhelmed, the cell is exposed to reactive oxygen species (ROS), triggering oxidative modifications. The antioxidant system includes several enzymes, such as peroxiredoxin 2 (Prx2), glutathione peroxidase (GPx) and catalase (CAT); in spite of their roles in cell defense being known, the interplay between these peroxidases is still unclear. The recent report of conoidin A, as a specific Prx2 inhibitor, offers the possibility to further explore the roles and contribution of these enzymes to antioxidant defense.
Aims: We aimed to study the importance of Prx2, GPx and CAT inhibition on defense against oxidative stress in normal erythrocytes.
Methods: We performed *in vitro* assays (*n*=3) with RBCs from healthy volunteers, inhibiting Prx2, GPx and CAT, either individually, two-by-two or all three; conoidin A, mercaptosuccinic acid and sodium azide were used as specific inhibitors of Prx2, GPx and CAT, respectively. Since the RBC membrane is a major target of ROS, we evaluated membrane lipoperoxidation (LPO) and membrane bound haemoglobin (MBH), as well as, cytosol's total antioxidant status (TAS), by spectrophotometric methods.
Results: Concerning TAS we found a trend towards decreasing values with enzyme inhibition (one or more); the lowest value of TAS was observed when all three enzymes were inhibited and, when only two enzymes were inhibited, the lower values were obtained for pairs that included CAT inhibition; when only one enzyme was inhibited, GPx inhibition showed the lowest TAS. Regarding LPO, a trend towards increasing values with enzyme inhibition was observed; the lowest value was obtained when all enzymes were active, and the highest when all of them were inhibited; when only one enzyme was inhibited, CAT inhibition showed the highest LPO value and when two enzymes were inhibited, LPO was highest for the pairs that included GPx. MBH was increased for all enzyme inhibitory conditions, when compared to the condition with all enzymes active, excepting when CAT was inhibited.
Summary/Conclusions: In conclusion, inhibition of these antioxidant enzymes, either alone or simultaneously, leads to oxidative stress modifications within the RBC, as showed by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or with other enzymes) presented more impact on oxidative modifications than Prx2 inhibition. Our data strengthens the importance of these enzymes in RBC's

antioxidant homeostasis, and suggests that inhibition or injury to one (or more) compromises erythrocytes, which might influence clinical presentation in oxidative stress associated anemias.

MOLECULAR BASIS OF PKLR MUTATIONS IN PATIENTS WITH PYRUVATE KINASE (PK) DEFICIENCY: THE FIRST REPORT FROM SOUTHEAST ASIAN POPULATION

S. Riolueang[1,*], K. Tachavanich[2], S. Ekwattanakit[3], V.S. Tanphaichitr[2], H. Kanno[4], V. Viprakasit[5]
[1]Siriraj-Thalassemia Center, [2]Department of Pediatrics, [3]Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, [4]Department of Transfusion Medicine and Cell Processing, Tokyo Women's Medical University, Tokyo, Japan, [5]Department of Pediatrics, of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Recently we have identified a new form of transfusion dependent hemolytic anemia due to *KLF*1 mutations causing a *trans*-acting deactivation of pyruvate kinase genes (*PKLR*). Mutations of *PKLR per se* can affect red blood cells metabolism and cause a wide range of clinical manifestation from fetal anemia leading to hydroptic fetus, severe neonatal jaundice requiring multiple exchange blood transfusions, chronic to fully compensated hemolytic anemia. Understanding of the molecular basis of pyruvate kinase deficiency (PK def.) might be useful to predict clinical phenotypes and suggest appropriate clinical management of future patients. Moreover, an interaction of *PKLR* and *KLF1* mutations in such patient has not been explored.
Aims: This study aim to identify the mutation of patients with PK def. for the first time in Southeast Asian populations.
Methods: Seven unrelated patients; 6 from Thailand and 1 from Indonesia have been enrolled after inform consent. We have measured the PK activity of all patients and their parents and siblings using a standard biochemical technique as we have described earlier. A complete genomic analysis of all *PKLR*'s exons (NM_000298.5) including exon-intron boundaries were selectively amplified and followed by direct Sanger sequencing.

Table 1.

Table 1 Summary of baseline hematology, clinical phenotypes, PK activities and PKLR mutations in 7 Southeast Asian families with PK deficiency

Cases	sex	Hct (%)	Hb (g/dl)	Rbc (x10⁶/ml)	MCV (fL)	MCH (pg)	MCHC (g/dl)	RDW (%)	Retic (%)	Phenotype	PK activity (U/gHb (normal >18.5±4.0))	PK activity (% of normal range)	PKLR genotypes (NM_000298.5) allele 1	allele 2

NA; not available, HA; hemolytic anemia, all mutation are described in HGVS nomenclature, In PK-1, the PK activity was performed after bone marrow transplantation (BMT)

Results: Seven index PK def. patients as confirmed by enzyme activities, age range 9-35 yrs old, were identified (Table 1). Three patients presented with severe hemolytic anemia and required regular blood transfusion; every 3-4 weeks in two (PK-1 and PK-3) and every 10-12 weeks (PK-2) in which one patient (PK-1) has been successfully treated with bone marrow transplantation and became transfusion-free. Three patients (PK-5, -6 and -8) had moderately severe hemolytic anemia and required blood transfusion occasionally. Only one patient (PK-7) from Indonesia had well-compensated anemia and never required blood transfusion. All but one had PK activities lower than 50% of normal range but these activities did not correlate with clinical severity. We found 11 different mutations in 5 compound heterozygotes and 1 homozygote as shown in Table 1. Four mutations appeared to be novel as they were not been reported in any public databases (c.1269+3A>G; c.353A>G =p.N118S; c.865C>T =p.R289W; c.1618G>T =p.G540X). One mutation (c.941T>C=p.I314T) seemed to be recurrent since it was found in two families; one homozygous and one compounded with N118S. Beside nucleotide mutations, we found a 5006 bp deletion from intron 3 to exon 10 affecting PKLR gene. To detect these mutations in family members and further cases, we developed a long range GAP-PCR analysis to amplify the breakpoint fragment and directly sequenced to determine deletion extends and also ARMS-PCR (C.1641T>TA), PCR-RFLP (c.941T>C), mismatched PCR-RFLP for c.1403C>G, c.1463G>A and IVS9(+3)A>G). Interestingly, one index patient (PK-4) was found with only one known missense mutation (R488Q), however we could not find any mutation in KLF1 of this patient suggesting that she might have other unidentified *cis* mutation involved gene regulation of *PKLR*. Due to a limited number of patients, there was no clear genotype-phenotype correlation found in our studied population.
Summary/Conclusions: Seven confirmed cases of PK def. are reported herein. They showed a wide variation of clinical severity. Molecular basis of PKLR mutations was proven to be beneficial to provide a definitive diagnosis of PK def. and might help suggesting clinical presentation in future cases.

PRELIMINARY RESULTS OF GAU-PED STUDY: PREVALENCE OF GAUCHER DISEASE IN PAEDIATRIC PATIENTS SELECTED BY AN APPROPRIATE DIAGNOSTIC ALGORITHM

W. Morello[1,*], M. Filocamo[2], M. Stroppiano[2], M. Di Rocco[3], F. Fedeli[4], G. Russo[5], D. Sperli[6], F. Furlan[7], A. Pession[1]
[1]Pediatric Hematology and Oncology Unit, Sant'Orsola-Malpighi University Hospital, Bologna, [2]Centro di Diagnostica Genetica e Biochimica delle Malattie Metaboliche, [3]Department of Pediatrics, Unit of Rare Diseases, Gaslini Institute, Genoa, [4]Pediatric Hematology, Ospedale Niguarda, Milano, [5]Pediatric Hematology and Oncology Unit, Azienda Policlinico-Vittorio Emanuele Università di Catania, Catania, [6]Pediatric Hematology and Oncology Unit, S. O. "Annunziata", Cosenza, [7]Pediatric Department, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disease characterized by the deficient activity of beta-glucocerebrosidase (GBA). GBA deficiency results in the accumulation of glucosylceramide in different organs, causing tissue damage. Typical GD features are splenohepatomegaly, peripheral blood cytopenias (mostly thrombocytopenia and/or anemia), growth retardation, bone involvement, gammopathies, increased risk of malignancies and, in some patients, neurological manifestations. Since symptoms are non-specific, the diagnosis can be delayed for years or missed. Enzyme replacement therapy (ERT) with recombinant β-glucocerebrosidase is safe and effective in preventing and/or reversing many clinical manifestations. However, if the diagnosis is delayed for years, major complications cannot be reversed. A useful screening method for GD is based on measuring enzyme activity on a Dried Blood Spot (DBS), while the gold standard test is still considered GBA activity in cellular homogenates. A pediatric algorithm has been proposed to promote timely diagnosis and early access to ERT (figure 1).

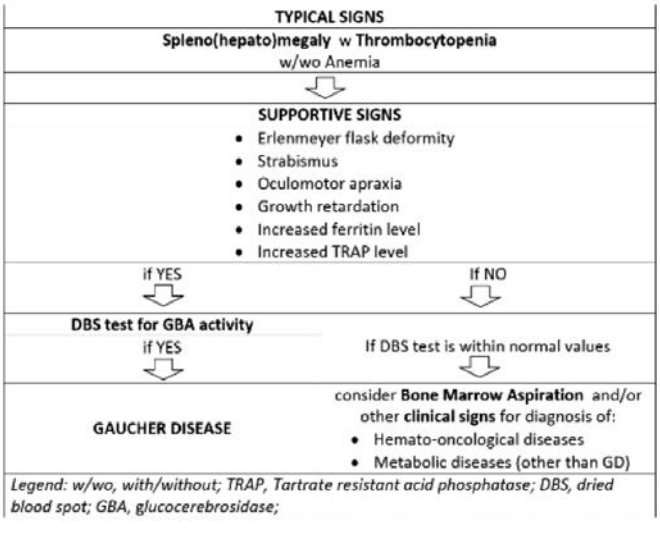

Figure 1 - Diagnostic approach for Gaucher disease in children (modified from *Di Rocco M et Al, Ped Blood & Cancer 2014;61:1905-09)*

Figure 1.

Aims: Since pediatric patients with splenomegaly and cytopenias are usually referred to pediatric hematologists, we have designed the GAU-PED study to

evaluate the prevalence of GD among children referred to the haematology paediatric units and selected according to the above mentioned diagnostic algorithm. Here, we report a preliminary analysis of GAU-PED trial.
Methods: The GAU-PED study involves 53 centers in the context of the AIEOP Study Group, the Italian clinical research consortium in paediatric hematology and oncology. Patients referring to the pediatric hematology and oncology units for splenomegaly with or without hepatomegaly and cytopenia (thrombocytopenia and/or anaemia), where other causes of splenomegaly has been excluded, are tested for GBA activity though a DBS sample. Only patients with DBS showing a GBA activity below normal values are recalled to confirm GBA enzyme deficiency using the gold standard GBA analysis in cell omogenate. For every tested patient, clinical information are also collected.
Results: After parental consent, a total of 25 DBS have been collected from 11 centers, in the first 12 months of study accrual. DBS values under 4.4 pmol/punch_1/h_1were found in 9/25 patients (36%). These patients have been recalled for the conventional enzymatic test. The diagnosis of GD has been confirmed in 5/9 patients (55%), with a prevalence of GD of 20% (95% CI, 8.8-39.1%) equal to 5/25 patients in the tested population. In all 5 patients the genetic analysis has been consistent with GD. Three patients were males and 2 females. The mean age at diagnosis was 8 years (range 2-13 years). The median time from the initial clinical presentation and diagnosis has been 12 months (range 6-50 months), while the mean time between the DBS test and the diagnosis has been 2 months. ERT has been started in all GD patients.
Summary/Conclusions: Our preliminary results support the use of DBS as screening test for GD in a selected population of children with splenomegaly and/or thrombocytopenia considered at increased risk for the disease. The use of an appropriate diagnostic algorithm is useful to increase awareness of GD among pediatric hematologists and to shorten the time to diagnosis. Taking into consideration the long life expectancy of pediatric GD patients, the early diagnosis will have a strong impact on health and quality of life.

CIRCULATING MICROPARTICLES IN CONGENITAL AND ACQUIRED HAEMOLYTIC ANAEMIA

W. Barcellini[1,*], V.M. Sciumbata[1], J.A. Giannotta[1], A. Zaninoni[1], V.B. Valli[1], G. Merati[2], E. Trombetta[3], V. Ferri[1], L. Pettine[1], A. Cortelezzi[14], A. Artoni[2]
[1]UOC Oncoematologia, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [2]UOC Ematologia non tumorale e Coagulopatie, [3]UOC Laboratorio Centrale di Analisi Chimico Cliniche e Microbiologiche Dipartimento dei Servizi, Servizio di Citofluorimetria, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [4]Università degli Studi, Milano, Italy

Background: Microparticles (MPs) are small particles budding from cells, which contain variable amounts of proteins, miRNA and cytosol from the parental cell. MPs play a role both in physiological and pathological conditions such as signal transduction, cell activation, thrombosis and cancer. Thrombotic events are a possible complication of haemolytic conditions, both congenital and acquired. Elevated levels of circulating MPs have been described in several haemolytic conditions, including sickle cell anaemia, thalassemia intermedia, haemolytic uremic syndrome, and thrombotic thrombocytopenic purpura.
Aims: To evaluate platelet MPs (PMP), tissue factor expressing MPs (TFMPs), endothelial MPs (EMPs) and microparticles expressing single antigens (CD41, CD144 or CD142) levels in in other haemolytic anaemias, such as hereditary spherocytosis (HS), elliptocytosis (HE), stomatocytosis (HSt), red cell enzymatic defects, congenital dyserithropoietic anaemia (CDA), autoimmune haemolytic anaemia (AIHA), and paroxysmal nocturnal haemoglobinuria (PNH).
Methods: To determine MPs, whole blood was collected into 0.109 M sodium citrated vacutainer tubes. Platelet Free Plasma (PFP) was prepared by double centrifugation at 2500 g for 15 min and stored frozen at -80°C until assayed. For MPs analysis 25 µl of PFP was incubated with annV-APC, CD41-FITC, CD142-PE and CD144 PerCp-Cy5.5 in Hepes buffer in the presence of 15 mM CaCl2 and 1 u/ml of r-Hirudin for 30 min. Samples were diluted with 500 µl Annexin V binding buffer and 25 µl of Flow-Count fluorospheres were added to express MP count as absolute numbers. MPs analyses were performed on a BD FACS Canto cytometer using Megamix-Plus SSC to define the MPs gate.
Results: MPs levels were evaluated in plasma of 43 patients followed-up for a median time of 9 years (range 2-34) and compared with normal controls. The median age of patients (15 male and 28 female) was 53 years (range 22-87), 9/43 (21%) had been splenectomized and 13/43 (30%) were treated at the moment of the study (steroids/immunosuppressors for AIHA, and eculizumab for PNH). Table shows Hb levels, PLT and WBC counts of the different haemolytic conditions, along with LDH and reticulocyte values. In AIHA, the number of EMP was negatively correlated with Hb levels (p<0.05), and PMPs positively with reticulocytes and LDH (p<0.05 for both); CD41+ MPs, CD142-PE+ MPs, PMPs, TF-MPs, and EMPs positively correlated with disease duration (p<0.05). In membrane defects the following positive correlation were observed: CD41+ MPs and PMPs with platelet values and EMPs with LDH (p<0.05 for all). In PNH, annV APC and CD144+ MPs were positively correlated with reticulocyte counts (p<0.05). In CDAs, the number of annV APC and PMPs negatively correlated with Hb (p<0.05). Finally, the number of annV APC was increased in PKD compared with controls (p=0.023), and positively correlated with disease duration (r=0.999, p<0.001); PMPs and TF-MPs were elevated too, although not significantly. The number of MPs here investigated were comparable between splenectomized and not splenectomized, and between naive and treated cases.

Table 1.

	AIHA (n=18)	Membrane defects (n=10)	PNH (n=7)	CDAs (n=5)	PK deficiency (n=3)	Controls (n=9)
Hb (mg/dL)	11.3 (6.7-15.4)	11.3 (9.7-16.4)	10.7 (7.6-12.7)	9.7 (7.7-10.5)	11.3 (6.7-15.4)	NR

TF-MPs/µL	30* (7,6-86)	22* (9,2-51)	21 (15-51)	20 (8,2-35)	75 (59-399)	43 (11-145)
EMPs/µL	12,3 (1,9-43)	11,1* (3,7-19,3)	9,5* (2,7-16,1)	9,5 (2,7-24,2)	17,4 (14,8-70,7)	20 (7-48)

Values are expressed as median (range). NR = Normal Ranges (Hb: 13.6-16.7 g/dL; LDH: 240-480 U/L; PLT : 130-400 10^9/L; reticulocytes: 16-84x10^9/L; WBC: 4,8-10,8 10^9/L).
*= p< 0,05 versus controls

Summary/Conclusions: These preliminary results suggest that MPs levels are abnormal in both congenital and acquired haemolytic conditions. MPs levels correlate with the degree of anaemia and haemolysis and with the duration of disease.

E1079

THE PREVALENCE, ETIOLOGY AND PROGNOSTIC IMPACT OF ANEMIA IN OLDER POPULATION

S.S. Michalak[1], J. Rupa-Matysek[2], L. Gil[2,*]
[1]Family Medicine Clinic, MEDKOL, Zielona Gora, [2]Department of Hematology and Bone Marrow Transplantation, Poznan University of Medical Sciences, Poznan, Poland

Background: The population of people aged ≥60 years is growing rapidly. Anemia represents a common condition among the elderly, however its prevalence and causes are not well known.
Aims: The aim of the study was to evaluate the prevalence, severity and etiology of anemia in the population aged ≥60 years. Risk factors for the development of anemia including concomitant diseases and treatment, were analysed. The association between anemia and hospitalization or all-cause mortality during follow-up was determined.
Methods: Retrospective analysis was performed on 981 Caucasian, outpatient patients aged ≥60 in Poland over 2013-2014 (median age 68, range 60-99 years, 60% females). The prevalence of anemia, defined according to WHO criteria, by gender, age groups (60-69, 70-79, and ≥80) and anemia etiology were studied. Data on the incidence of common comorbidities (coronary artery disease, heart failure, diabetes, chronic obstructive pulmonary disease, chronic kidney disease, chronic liver diseases, cancer, thyroid diseases), hospitalization, treatment used and all-cause mortality were analysed.
Results: The prevalence of anemia in the studied population was 17.2% and was higher in men than women (20.4% *vs* 15.2%, p=0.038). Anemia was present in 10.3% of patients aged 60-69, in 20.1% of those aged 70-79 and in 35.6% of patients ≥ 80 years. Incidence rates of anemia increased significantly with age (60-69 *vs* 70-79 years, p<0.001; 60-69 *vs* ≥80 years, p<0.001, 70-79 *vs* ≥80 years, p<0.001). Anemia was mild in 69.8% of patients, but a severe form was found significantly more often among men aged ≥80 years (p=0.03). Analysis of the etiology of anemia revealed three predominant types: anemia of chronic disease (33.1%), unexplained anemia (28.4%) and deficiency anemia (22.5%, including iron deficiency 13%). In comparison to patients without anemia, those with anemia were older (p<0.001), had a higher prevalence of comorbidities (p<0.001) and were more often hospitalized (p<0.001). In the multivariate logistic regression model, factors increasing the risk of anemia were: age ≥80 years (OR=2.29; 95%CI 1.19-4.42; p=0.013), the number of comorbidities (2 diseases OR=2.85; 95%CI 1.12-7.30; p=0.029, 3 diseases OR=6.28; 95%CI 2.22-17.76; p=0.001, 4 diseases OR=4.64; 95%CI 1.27-17.01; p=0.021) and the number of hospitalizations (OR=1.34; 95%CI 1.13-1.58; p=0.001). At the end of the 2-yr follow-up, the cumulative survival among patients without anemia in relation to the group with anemia was 90.76% *vs* 78.08% and the difference was statistically significant (p<0.001). In multivariate model, factors that significantly increased the risk of death in study population were anemia (HR=3.33; 95%CI 1.43-7.74; p=0.005), cancer (HR=3.31; 95%CI 1.47-7.49; p=0.004) and heart failure (HR=2.94; 95%CI 1.33-6.51; p=0.008).
Summary/Conclusions: In patients ≥60 years the incidence of anemia increases with age and male gender, number of comorbidities and frequency of hospitalization. The high rate of unexplained anemia indicates the necessity for detailed hematologic diagnosis. The occurrence of anemia among people aged ≥60 years has an adverse impact on survival.

E1080

PIEZO1 MECHANOTRANSDUCTIVE PROTEIN MUTATIONS IN RBCS: WHEN THE PHENOTYPE IS BEYOND HAEMOLYTIC ANAEMIA

D. Mota[1,*], S. Marini[1], T. Nascimento[1], P. Bernardo[1], L. Relvas[1], A. Oliveira[1], E. Cunha[1], J. Ribeiro[1], C. Bento[1], T. Magalhães Maia[1], M.L. Ribeiro[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Piezo proteins are integral membrane proteins with many transmembrane domains broadly expressed, including erythrocytes (RBCs). PIEZO1 proteins play an important role as an osmoreceptor, maintaining RBCs ionic homeostasis, functioning as a mechanically activated cation channels. Mutated PIEZO1 proteins have been linked to hereditary xerocytosis (HX), which is characterized by RBCs dehydration with mild to moderate compensated haemolytic anaemia and iron overload. As these clinical features are present in many different clinical conditions, the diagnosis always needs a high level of suspicion. Nowadays, besides peripheral blood smear (PBS) observation, molecular analysis, searching for mutations in PIEZO1 gene, became a tool in the diagnosis of HX.
Aims: Describe 26 patients with HX associated with PIEZO1 mutations belonging to 13 unrelated families, raising awareness of the highly variable phenotype of this patients, and the need of a highly grade of suspicion along with the morphologic evaluation of the PBS.
Methods: Collection of clinical and laboratory data on our 26 patients with HX and hyperferritinemia due to 10 different identified mutations in PIEZO1. Sanger sequencing was used to identify mutations affecting PIEZO1, encoded by *FAM38A* gene, and to confirm transmission according to the presence of disease phenotype. In all patients were excluded other known causes of hyperferritinemia (HF) and haemolytic anaemia.
Results: Of the 26 patients identified as having PIEZO1 mutations, 13 were probands and 13 were identified by family studies. Median age at diagnosis was 43 years (1-80), with female predominance (n=14; 53.9%). 4/13 probands had family history of HX (n=1) or HF (n=2). The common feature of our entire cohort of patients was the presence of xerocytes in PBS. 13/26 patients had reticulocytosis with a median reticulocyte count of $101x10^9$/L (28.1-557.3), 18/26 patients have HF with a mean value of ferritin of 556ng/mL (161-6617) and 9/26 had both. Of the 26 patients, four had splenomegaly and six gallbladder lithiasis (5/6 cholecystectomized), two of them have both. Only 5 patients presented with anaemia (Hb <12g/dL), 2 macrocytic and 3 normocytic. One patient was microcytic because he also was a β-thalassemia carrier. We detected heterozygous missense mutations in all 26 patients.
Summary/Conclusions: HX is a dominant disorder of RBCs dehydration presenting a great phenotypic variability. As shown in our cohort of patients, the anaemia may not be the main feature, in fact, the presence of xerocytes in PBS and HF were the most frequent characteristics of our patients. We would like to emphasise that in the genomics era the identification of xerocytes in the PBS keeps playing an important role for this diagnostic. Not only because, unlike other haemolytic anaemias, in HX there is a contraindication to splenectomy due to the increased risk of thrombotic events, but also because this patients present an iron overload that is not proportional to the degree of hemolysis. This iron overload may be related to a defective iron homeostasis dependent on PIEZO1 function not strictly related with Xerocytosis.

MODELLING PYRUVATE KINASE DEFICIENCY IN HUMAN PROGENITORS USING CRISPR/CAS9

S. López-Manzaneda[1,2,*], R. Torres[3], E. Olivier[4], A. García-Torralba[1,2], R. Sanchez-Dominguez[1,2], O. Alberquilla[1,2], J. Mountford[4], J.C. Ramírez[5], J.A. Bueren[2,6], J.C. Segovia[1,2]
[1]Cell Differentiation and Cytometry Unit. Hematopoietic Innovative Therapies Division, CIEMAT/CIBERER, [2]Unidad Mixta de Terapias Avanzadas, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, [3]Molecular Cytogenetics Group, Human Cancer Genetics Program, Spanish National Cancer Research Centre – CNIO, Madrid, Spain, [4]Scottish National Blood Transfusion Service and ICAMS, University of Glasgow, Glasgow, United Kingdom, [5]VIVEbioTECH, San Sebastian, [6]Hematopoietic Innovative Therapies Division, CIEMAT/CIBERER, Madrid, Spain

Background: Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD produces chronic non-spherocytic hemolytic anemia, which can be fatal during early childhood and may result in lifelong transfusion dependence that in some instances persists despite therapeutic splenectomy. Although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. We developed a gene therapy strategy in a PKD mouse model using a lentiviral vector (LV) carrying a codon-optimized version of the PKLR cDNA (coRPK). This vector has been recently designated as Orphan Drug for the treatment of PKD by the EMA and FDA (EMA: EU/3/14/1330; FDA: DRU-2016-5168).
Aims: To test the efficacy of the therapeutic LV, we have proposed an alternative to patient-derived PKD-hematopoietic progenitors. In particular, we have generated CRISPR/Cas9 system tools to knock-out the PKLR gene in healthy hematopoietic progenitors from healthy cord blood samples
Methods: Up to six different gRNAs were specifically generated to cleave the exons 8, 9 and 11 of the PRLR gene. All gRNAs contain at least 3 mismatches with the coRPK present in the therapeutic LV, to avoid the cleavage of the therapeutic transgene. Two gRNAs cleaved the PKLR gene both in 293T cells and primary $CD34^+$ cells. In order to identify and select edited cells, Cas9-gRNAs components were cloned into a Cas9-2A-ZsGreen1 plasmid.
Results: Cord Blood $CD34^+$ cells were electroporated, sorted and differentiated *in vitro* along the erythroid lineage. Significantly, the pyruvate kinase activity in *ex vivo* differentiated erythroid cells was impaired in gene edited cells as compared to non-edited samples.
Summary/Conclusions: Gene edit of wt CD34+ progenitors allow us to generate cells with RPK impaired. The decrease of PK activity validates this approach as a human model for PKD.

PHYSIOPATHOLOGY OF HEREDITARY XEROCYTOSIS : PIEZO1 GAIN OF FUNCTION MUTATIONS IMPACT HEMOGLOBIN OXYGEN AFFINITY

L. Kiger[1], C. Guitton[2], K. Ghazal[3], M. Feneant-Thibault[4], L. Bendelac[5], F. Galacteros[6], V. Proulle[7], L. Garçon[8], V. Picard[5,*]
[1]IMRB U955, INSERM, Créteil, [2]Service de Pédiatrie, [3]Service de biochimie, APHP, Hopital Bicêtre, [4]Service de biochimie, [5]Service d'hématologie biologique, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, [6]Centre de Reference des maladies constitutionnelles du Globule rouge, APHP Hopital Mondor, Créteil, [7]Service d'Hématologie, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, [8]Service d'hématologie biologique, CHU, Amiens, France

Background: Dehydrated hereditary stomatocytosis, also called hereditary xerocytosis (HX) is a dominant non-spherocytic chronic hemolytic anemia characterized by an increased cation leak through the red cell membrane, associated with dehydration and shortened red cell survival. Clinically, most patients present a totally compensated hemolysis, with a normal hemoglobin level contrasting with a high reticulocytosis. In most cases, HX is caused by missense mutations activating Piezo1, a mechanosensitive ion channel. However, the pathophysiology of this compensated hemolysis remains largely unclear.
Aims: We studied the hemoglobin oxygen affinity parameters in HX patients and in hereditary spherocytosis (HS) subjects as controls.
Methods: Fourteen patients from 5 described and 4 unreported families with a HX diagnosis and 15 HS subjects were included. Diagnosis was based on ektacytometry and EMA assay. PIEZO1 and KCNN4 coding regions were analyzed by Sanger sequencing in all HX patients. Hemoglobin oxygen affinity was evaluated using p50 measured on venous blood on a Hemoxanalyser or a Radiometer blood gas analyzer. 2,3 diphosphoglycerate (2,3 DPG) levels were measured using a commercialized kit and expressed as a molar ratio 2,3 DPG/hemoglobin.
Results: All the 14 HX patients carried one or two missense mutations in PIEZO1, no gene variation was identified in KCNN4. Five families (9 subjects) have already been reported, with identified mutations in exon 18, 21, 42 or 51. Five subjects from 4 new families carried new mutations in exons 14, 16 and 29 and 51 for which bioinformatic softwares showed a high likelihood of pathogenicity. For all HX patients, p50 values were under the normal range (mean 21,1, range 19,7-23,4, normal range 25-29 mmHg), contrasting with HS patients for whom p50 was found to be in the normal range (mean 26,1, range 24,6-28,8 mmHg). This indicated a significant increase in the hemoglobin affinity for oxygen restricted to PIEZO1 mutated HX. Of note, p50 was not correlated with the Hb level (mean 139, range 112-180 g/L in HX patients *versus* 125, range 93-142 g/L in HS patients). Intracellular red cell 2,3 DPG level could be measured in 7 HX patients from 4 families, it was found decreased in all of them (0,43+/-0,06, normal 0,9+/-0,19), providing a pathophysiological basis for the increased hemoglobin oxygen affinity we observed.
Summary/Conclusions: The increased hemoglobin affinity for oxygen observed in HX patients reflects the decrease in the 2,3 DPG level. This may be a consequence of a high ATP requirement and an increased glycolytic activity in HX red cells at the expense of the 2,3DPG shunt in order to maintain the cell ion homeostasis. High hemoglobin affinity for oxygen may induce a relative tissue hypoxia and consequently a high reticulocytosis, providing a clue to explain the compensated hemolysis frequently observed. However, the links between PIEZO1 mutations, red cell enzymatic activity and erythropoiesis need to be clarified and a proteomic and a metabolomic approach is under investigation. Of interest, on a clinical point of view, HX diagnosis is sometimes difficult and this low p50 value, easily measured on venous blood, represents a useful new diagnosis tool for HX.

Gene therapy, cellular immunotherapy and vaccination

SAFETY AND EFFICACY OF MULTI-PATHOGEN-SPECIFIC T CELLS IN A HUMANIZED MODEL OF INVASIVE ASPERGILLOSIS: A PROOF OF CONCEPT STUDY

A. Papadopoulou[1,*], K. Koukoulias[12], M. Alvanou[1], E. Athanasiou[1], N. Savvopoulos[1,2], T. Vyzantiadis[3], E. Siotou[1], M. Gounis[1], P. Kaloyannidis[4], M. Yiangou[2], A. Anagnostopoulos[1], E. Yannaki[1]
[1]Gene and Cell Therapy Center- Hematology Dpt- BMT Unit, George Papanicolaou Hospital, [2]School of Biology, Department of Genetics, Development and Molecular Biology, [3]School of Medicine, 1st Department of Microbiology, Aristotle University of Thessaloniki, Thessaloniki, Greece, [4]Adult Hematology & Stem cell Transplant, King Fahad Specialist Hospital, Dammam, Saudi Arabia

Background: Viral infections, most commonly by cytomegalovirus (CMV), Epstein-Barr virus (EBV), polyoma virus type I (BK), and fungal infections, mainly by Aspergillus Fumigatus (Asp), are leading causes of transplant-associated mortality in patients undergoing allogeneic hematopoietic stem cell transplantation. Standard treatment with antiviral and antifungal pharmacological agents, is often ineffective or toxic and may lead to resistance. Due to these limitations, adoptive immunotherapy with antigen-specific T cells has emerged as an attractive alternative. Towards unleashing its full potential and treat multiple viral and fungal infections by a single T-cell product, we developed a rapid, simplified and minimally laborious protocol for the generation of multipathogen-specific T cells (mp-STs) that simultaneously target CMV, EBV, BK and Asp, from healthy donors.
Aims: Due to the lack of mouse models recapitulating the clinical condition of multiple opportunistic infections in transplanted hosts, we here aimed to test the *in vivo* safety of produced mp-STs and provide a proof of concept of their efficacy in a humanized model of invasive aspergillosis (IA).
Methods: mp-STs were generated from healthy donors by pulsing $1.5x10^7$mononuclear cells with viral (CMV: IE1, pp65; EBV: EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp pepmixes (Crf1, Gel1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of $1.5x10^7$of immunomagnetically isolated CD3+cells (donor lymphocyte infusions-DLI) or mp-STs were infused in myelo/immuno-ablated NSG mice which had been intranasally inoculated with Asp conidia or left uninfected. Mice were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assessed by histology and immunohistochemistry.
Results: We generated $23±5x10^7$ cells mp-STs (12-fold expansion). All cell lines were polyclonal expressing central and effector memory markers and specific against Asp [spot forming cells (SFC)/$2x10^5$cells: 315±82] and the targeted viruses, if derived from seropositive donors [SFC/$2x10^5$cells, CMV: 637±267; EBV: 744±158; BK: 578±118). To first address the safety issue, we asked whether mp-STs can induce acute graft-versus-host disease (aGvHD) in myelo/immuno-ablated mice. While DLI-treated mice developed clinically and histologically confirmed aGvHD and succumbed by day 20, mp-ST-mice survived free of aGvHD until the day of sacrifice (d28). To assess the *in vivo* functionality of mp-STs against IA, conditioned and Asp-inoculated mice, received mp-STs (n=5), DLI (n=4) or were left untreated (IA control, n=6). All IA- and DLI-mice succumbed to histologically evidenced IA at a median day 6, whereas 60% of mp-ST-mice survived until sacrifice, at day12. While the day-12 survivors presented high T-cell engraftment in the lung (% $CD3^+/CD45^+$: 14±7) with no histological evidence of IA, the two mp-ST-non-survivors died from IA in the absence of T-cell engraftment. Non-specific DLI failed to control IA despite T-cell presence in 3/4 DLI-mice (%$CD3^+/CD45^+$spleen: 58±12, lung: 3±1) which succumbed early, before aGvHD development.
Summary/Conclusions: Overall, engrafted mp-STs effectively controlled IA without evidence of alloreactivity. Based on the robust specificity of our mp-STs against all targeted pathogens and the clinical efficacy of virus-specific T-cells, we expect that our "four in one" T-cell product has the potential to also fight the targeted viruses and become a powerful tool for the treatment of multiple, life-threatening post-transplant infections.

DONOR LYMPHOCYTE INFUSION IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES LEADS TO DIVERSITY OF LEUKEMIA-ASSOCIATED-ANTIGENS-SPECIFIC T CELL RESPONSES AND TO REDUCTION IN REGULATORY T CELL FREQUENCY

S. Hofmann[1], M. Schmitt[1], M. Götz[2], H. Döhner[2], M. Wiesneth[3], D. Bunjes[2], J. Greiner[2,4,*]
[1]Clinic for Internal Medicine V, University of Heidelberg, Heidelberg, [2]Clinic for Internal Medicine III, University of Ulm, [3]Institute of Clinical Transfusion Medicine and Immunogenetics Ulm, German Red Cross Blood Transfusion Service Baden-Württemberg–Hessen and Institute of Transfusion Medicine, Ulm, [4]Department of Internal Medicine, Diakonie Klinikum, Stuttgart, Germany

Background: Cytotoxic T-cell (CTL) responses against malignant cells play a major role in maintaining remission and prolonging overall survival in patients with hematologic malignancies after allogeneic stem cell transplantation (allo-SCT) and/or donor lymphocyte infusions (DLI). Graft *versus* leukemia (GvL) effects after allogeneic stem cell transplantation and/or DLI are considered to be T cell-mediated. Many groups described specific T-cell responses against several leukemiaassociated antigens (LAA) in different hematological malignancies. However, T cell responses after allo-SCT and DLI are not well characterized.
Aims: In this study, we analyzed LAA-specific T cell responses after allo-SCT and DLI. To this end, we assessed the frequency and diversity of LAA-specific CD8+ T cells using ELISpot analysis and tetramer assays in 12 patients (5 patients (pts) with acute myeloid leukemia, 2 pts with chronic myeloid leukemia, 3 pts with multiple myeloma and 2 pts with chronic lymphatic leukemia) before and after DLI. Epitopes derived from PRAME, $NPM1^{mut}$, RHAMM, WT-1 and other LAA were tested. Moreover, the frequency of regulatory T (Treg) cells was measured and the course of cytokine profiles before and after DLI was analyzed. These immunological findings were correlated to the clinical course in the respective patients.
Methods: In ELISpot and tetramer assays, an increase in frequency and diversity of LAA-specific T cells was observed in all patients. Cytokine assays using ELISA for the detection of more than 10 cytokines before and after DLI were employed.
Results: Importantly, there was a significant increase from 0 to 7 LAA-derived T cell epitopes (P=0.03) in clinical responders (R) when compared to non-responders (NR). These positive results in R *versus* NR where confirmed by tetramer-based flow cytometry assays, where an increase in frequency from 0.5 to 2.3% in the R group of LAA-specific T cell/all CD8+ T cells was observed. Interestingly, the frequency of Tregs in clinical responders decreased significantly from a median 72,9% to 54,6% (P=0.008) while the frequency of Tregs stayed stable over time in non-responding patients. T cell subset analysis did not reveal significant differences before *versus* after DLI administration. In cytokine assays using ELISA we found a significant increase of IL-4 after DLI.
Summary/Conclusions: Taken together, we detected an increase of specific CTL responses against several LAA after allogeneic stem cell transplantation and donor lymphocyte infusion. Moreover, this study suggests that broader LAA epitope-specific T cell responses as well as decreasing numbers of Tregs contribute to clinical outcome of patients treated with DLI.

GENE-MODIFIED NK-92MI CELLS EXPRESSING A CHIMERIC CD16/CD64-BB-Z RECEPTOR EXHIBIT ENHANCED CANCER-KILLING ABILITY IN COMBINATION WITH THERAPEUTIC ANTIBODY

Y. Chen[1,*], F. You[1], J. Li[1], X. Tang[2], G. An[1], H. Meng[1], L. Yuan[3], L. Yang[1]
[1]The Cyrus Tang Hematology Center, [2]Department of Hematology, Soochow University, Suzhou, Jiangsu, [3]Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Natural killer (NK) cells play a pivotal role in monoclonal antibody-mediated immunotherapy through an antibody-dependent cell-mediated cytotoxicity (ADCC) mechanism. NK-92MI is an interleukin-2 (IL-2)-independent cell line, which was derived from NK-92 cells with superior cytotoxicity to a wide range of tumor cells *in vitro* and *in vivo*. However, the Fc-receptor (CD16), which usually mediates ADCC, is absent in NK-92 and NK-92MI cells.

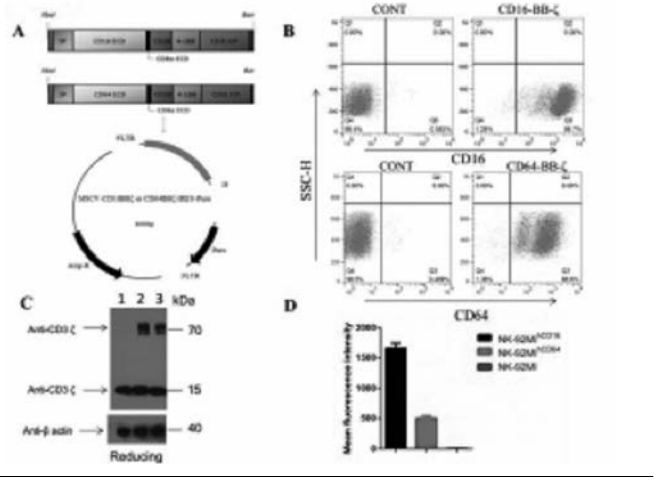

Figure 1. NK-92MIhCD16 and NK-92MIhCD64 functional validation in vitro and characterization. A. Schematic representation of the CD16-BB-ζ and the CD64-BB-ζ receptor constructs. B. Exogenous CD16 or CD64 expression on surfaces of NK-92MI cells are shown. C. Immunoblot analysis of CD3ζ fusion protein expression in NK-92MIhCD16 or NK-92MIhCD64 cells.

Aims: To apply NK-92MI cell-based immunotherapy in cancer, we designed and generated two chimeric receptors which can bind the Fc portion of human immunoglobulins in NK-92MI cells.
Methods: The construct included the low-affinity Fc receptor CD16 (158F) or the high-affinity Fc receptor CD64, with the addition of the CD8a extracellular domain, CD28 transmembrane domains, two costimulatory domains (CD28 and 4-1BB), and the signaling domain from CD3ζ. The resulting chimeric receptors, termed CD16-BB-ζ and CD64-BB-ζ, were utilized to generate chimeric receptor-modified NK-92MI cells, which were named NK-92MI^{hCD16} and NK-92MI^{hCD64} cells, respectively.
Results: We found that NK-92MI^{hCD16} and NK-92MI^{hCD64} cells significantly improved cytotoxicity against CD20-positive non-Hodgkin's lymphoma (NHL) cells in the presence of rituximab.
Summary/Conclusions: These results suggest that the chimeric receptor-modified NK-92MI cells could potentially enhance the clinical responses mediated by currently available anticancer monoclonal antibodies (mAbs).

Seràgnoli, Bologna, [10]Università Vita-Salute San Raffaele and IRCCS Istituto Scientifico San Raffaele, Milan, Italy, [11]Hematology, Hospital Universitari i Politècnic La Fe de Valencia, Valencia, Spain

Background: The PharmaFlow automated flow platform has achieved 85% clinical correlation with AML samples with its novel Native Environment assay. Recently, novel Bi-specific antibodies (BsAbs) or analogous constructions acting through the formation of an immunologic synapse between T-cells (CD3) and a tumor-associated surface antigen (TAA) have been used as immunotherapy leading to T-cell activation and serial lysis of tumor cells.
Aims: The aim of the present study is develop and *in vitro* assay with multiples variables to better quantify the activity of bispecific antibodies and reflect the interpatient variability.

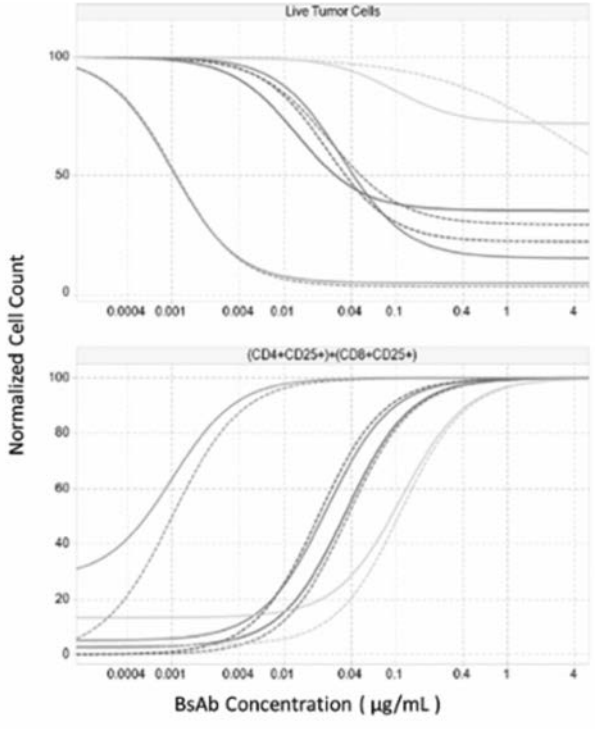

Figure 1.

Methods: For this purpose, different fresh whole Bone Marrow (BM) or Peripheral Blood (PB) were tested with their corresponding BsAbs at 8 different concentrations in different time points (24h-144h). In this sense, we tested 31 AML BM samples (5 paired BM and PB) with the CD123XCD3 (Creative Biolabs) and 7 CLL and 3 B-ALL samples with Blinatumumab (Amgen). When appropriate, basal quantification of TAA was performed by flow cytometry (FCM). The PharmaFlow platform efficiently count by FCM how many tumor cells are killed by every activated T-cells, here called effective E:T ratio. For each sample, 8-colour FCM staining was performed to simultaneously analyze the leukemic population, activated CD4 and CD8 T-cells and the residual normal cells. EC_{50} or E_{max} was calculated to evaluate potency or efficacy. Kinetics of activity was measured repeating the dose response curves in 3 different days.
Results: Most of the samples present both T-cell activation (CD25+) and an effective lysis of tumor cells after BsAbs exposure in a time and dose dependent manner (Figure 1), even starting with low basal E:T ratios (<1:100). For AML, basal quantification of CD123 by FCM density does not reflect a correlation with the *in vitro* response. By contrast, differences in T-cell cytotoxicity or leukemic immunoresistance were observed between samples in terms of EC_{50} or E_{max}, even more marked between CLL samples. The integration of effective E:T ratios, EC_{50}, E_{max}, and kinetics allow us to generate an *in vitro* response model and select those samples with higher T-cell cytotoxicity after the different BsAbs exposure. Interestingly, many of the samples for all the BsAbs leave a significant proportion of live cells, even at the higher BsAb concentrations or with a remarkable expansion of activated T-cells that suggest the use of immunecheckpoint to unblock this immnunoresistant status.
Summary/Conclusions: We have developed an automated flow cytometry assay for bispecific antibodies screening that keep intact both basal effector to target (E:T) ratios and Native environment using whole blood or bone marrow samples. In this context, the PharmaFlow platform selects different *in vitro* T-cytotoxicity effects across patients identifying best patient candidates for adoptive antitumor immunotherapy with BsAbs. The integration of Effective E:T ratios and pharmacological parameters better predict the *in vitro* response of BsAbs. Because of the high capacity of the PharmaFlow platform, additional antibodies constructions alone or in combinations with immunomodulatory agents could be tested to identify the better agents or immunotherapeutics combinations in hematological diseases.

E1087

HUMANIZED CD7 NANOBODY-BASED IMMUNOTOXINS EXHIBIT PROMISING ANTI-T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA POTENTIAL

Y. Yu[1,*], J. Li[1], X. Zhu[2], X. Tang[3], Y. Bao[4], Y. Huang[1], L. Yuan[5], L. Yang[1]
[1]The Cyrus Tang Hematology Center, Soochow University, Suzhou, [2]Department of hematology, The Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, [3]Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, [4]Binhu Hospital, the First People's Hospital of Hefei Group, Hefei, [5]Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Nanobodies, or named as VHHs, are derived from heavy-chain-only antibodies that circulate in sera of camelids. Their exceptional physicochemical properties, possibility of humanization and unique antigen recognition properties make them excellent candidates for targeting delivery of biologically active components, including immunotoxins. In our previous efforts, we have successfully generated the monovalent and bivalent CD7 nanobody-based immunotoxins, which can effectively trigger the apoptosis of CD7 positive malignant cells.
Aims: To pursue the possibility of translating those immunotoxins into clinics, we humanized the nanobody sequences (designated as dhuVHH6), as well as further truncated the *Pseudomonas* exotoxinA (PE) derived PE38 toxin to produce a more protease-resistant form which is named as PE-LR, by deleting majority of PE domain II.
Methods: Three new types of immunotoxins, dhuVHH6-PE38, dVHH6-PE-LR, and dhuVHH6-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in *E. coli* and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.
Results: Flow cytometry results revealed that all immunotoxins still maintained the ability to bind specifically to CD7-positive T lymphocyte strains without binding to CD7-negative control cells. Laser scanning confocal microscopy found that these proteins can be endocytosed into the cytoplasm after binding with CD7-positive cells, and that this phenomenon was not observed in CD7-negative cells. WST-8 experiments showed that all immunotoxins retained the highly effective and specific growth inhibition activity in CD7-positive cell lines and primary T-cell acute lymphoblastic leukemia (T-ALL) cells. Further *in vivo* animal model experiments showed that humanized dhuVHH6-PE38 immunotoxin can tolerate higher doses and extend the survival of NCG mice transplanted with CEM cells without any obvious decrease in body weight. Further studies on NCG mice model with patient-derived T-ALL cells, dhuVHH6-PE38 treatment significantly prolonged mice survival with around 40% survival improvement. However, it is also noticed that despite dhuVHH6-PE-LR showed strong anti-tumor effect *in vitro*, its *in vivo* anti-tumor efficacy is disappointed.

Summary/Conclusions: We have successfully constructed a targeted CD7 molecule modified nanobody (CD7 molecule improved nanobody) immunotoxin dhuVHH6-PE38 and showed its potential for treating CD7-positive malignant tumors, especially T-cell acute lymphoblastic leukemia.

E1088

STATINS MAY IMPROVE CAR-NK IMMUNOTHERAPY IN MM BY PREVENTING LOSS OF BCMA EXPRESSION ON MM CELLS

G. Suñe[1,*], L. Perez-Amill[1], A. Urbano-Ispizua[1], B. Martín-Antonio[1]
[1]Hematology, Hospital Clinic/IDIBAPS/Josep Carreras Leukemia Research Institute, Barcelona, Spain

Background: Chimeric Antigen Receptor (CAR) modified immune cells targeting BCMA against multiple myeloma (MM) has appeared as a feasible immunotherapy strategy to treat MM patients. However, high doses of CAR immune cells are required to achieve a response. Cord blood derived NK cells (CB-NK) is a feasible source of obtain NK cells to modify with a CAR against BCMA. We previously observed that MM cells exposed to CB-NK are able to transfer MM proteins, such as BCMA, both to CB-NK and to adjacent MM cells non-exposed to CB-NK. Furthermore, statins, which are toxic for MM cells, by altering the lipid composition of tumor cell membrane are involved in cell-cell communication. We hypothesized that statins could prevent the loss of BCMA expression which occurs in MM cells after CB-NK exposure, allowing infusing a lower CAR immune cell dose in MM patients
Aims: To evaluate the effect of statins on MM cell proliferation, on the CB-NK immune response against MM, and on BCMA expression in MM cells after CB-NK exposure.
Methods: The cytotoxicity of statins against MM cells was determined *in vitro* and *in vivo* in a murine MM model; furthermore, their impact in CB-NK cytotoxicity against MM was also determined *in vitro*. BCMA expression on MM cells after CB-NK exposure was analyzed by confocal microscopy and by flow cytometry. FACS sorting experiments were performed to analyze BCMA transfer between CB-NK exposed MM cells to neighboring non-exposed CB-NK MM cells.
Results: Atorvastatin and Fluvastatin treatment (1μM) decreased MM cell line (ARP1, RPMI, KMM1) proliferation. No effect was detected for U266 MM cells and for K562 non-MM cells. *In vivo* studies, showed that mice treated for three days I.P with Fluvastatin (1mg/kg) showed significant decreased MM disease progression. Blocking of BCMA decreased CB-NK cytotoxicity against MM cells. Furthermore, pretreatment of MM cells with Fluvastatin (3 μM) increased CB-NK cytotoxicity against all MM cell lines; no impact was observed against K562 non-MM cells. Co-culture experiments showed that, as soon as 30 minutes, CB-NK exposure led to a BCMA transfer from MM cells to CB-NK and to the extracellular milieu leading to a loss of BCMA expression on MM cells. Fluvastatin pretreatment prevented loss of BCMA expression. After two days of co-culture, alive MM cells still showed decreased BCMA surface expression, and surprisingly, increased intracellular BCMA expression. Fluvastatin pretreatment partially avoided the loss of BCMA surface expression and the increased intracellular BCMA expression. Furthermore, FACS sorting experiments showed that MM cells exposed to CB-NK, transferred BCMA to neighboring non-CB-NK exposed MM cells which was partially inhibited with Fluvastatin pretreatment.
Summary/Conclusions: Our findings show that besides the anti-MM activity of statins alone, they avoid the loss of BCMA expression on MM cells after immune cell exposure. Preventing loss of BCMA expression on MM cells might improve the efficiency of CAR immunotherapy against BCMA, suggesting the potential of statins as an adjuvant in CAR-NK immunotherapy against MM

E1089

DENDRITIC CELL VACCINATION COMBINED WITH LENALIDOMIDE AND PROGRAMMED DEATH-1 (PD-1) BLOCKADE HAS SYNERGISTICALLY INDUCED A MARKED TUMOR REGRESSION IN A MURINE MYELOMA MODEL

S.-H. Jung[1,*], M.-C. Vo[2], H.-J. Lee[2], T.J. Lakshimi[2], S. Yang[2], H.-J. Kim[1], J.-J. Lee[1]
[1]Department of Hematology-Oncology, [2]Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: There is an emerging evidence that the maximal benefit of dendritic cell (DC)-based cancer immunotherapy may be achieved by combination with other therapies that act to immunomodulation and tumor microenvironment.
Aims: In this study, we tried to obtain the best efficacy of immunotherapy using DC vaccination in combination with lenalidomide and PD-1 blockade in a murine myeloma model.
Methods: After establishing myeloma-bearing mice, five treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) DCs + lenalidomide, 4) DCs + PD-1 blockade, and 5) DCs + lenalidomide + PD-1 blockade. After treatment, preclinical response and *in vitro* immunological responses were evaluated.
Results: DCs combined with lenalidomide and PD-1 blockade showed the best tumor regression among the study groups. These anti-tumor effects have meaningfully related to the decrease of immuno-regulatory populations, such as myeloid-derived suppressor cells (MDSCs), M2 macrophages, and regulatory T cells (Treg) and the increase of effector immune cell populations, including $CD4^+$ and $CD8^+$ T cells, natural killer (NK) cells, and M1 macrophages, accompanied with the activation of cytotoxic T lymphocytes (CTLs) and NK cells in the splenocytes from the treated mice. Moreover, the level of immunosuppressive cytokines, such as TGF-β and IL-10, was significantly reduced in tumor microenvironment.
Summary/Conclusions: DC vaccination in combination with lenalidomide plus PD-1 blockade has synergistically induced a strong antitumor immunity by modulating tumor microenvironment in a murine myeloma model. This protocol will become a promising translational approach to improve the efficacy of immunotherapy in the field of MM.

B- AND T-CELL IMMUNE REPERTOIRE PROFILING WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING

J. Eberlein[1], T. Harrison[1], J. Sims[2], I. McKittrick[1], M. Wemmer[1], D. Fugere[1,*], L. Griffin[1], B. Culver[1], L. Johnson[1], B. Kudlow[1]
[1]ArcherDX, Boulder, CO, [2]Q2 Solutions, EA Genomics, Morrisville, NC, United States

Background: NGS-based analysis of the immune repertoire (IR) is a powerful tool to monitor disease, adaptive immune responses to disease, vaccination and therapeutic interventions. IR characterization by NGS usually requires large primer panels to cover its extensive combinatorial diversity, and a complex system of synthetic controls to account for differential amplification efficiency across segment combinations. Anchored Multiplex PCR (AMP™) uses molecular barcoded (MBC) adapters and gene-specific primers (GSPs), enabling NGS-based immune chain mRNA interrogation from a single side. This eliminates the need for opposing primers that bind within the highly variable V-segment, eliminating clone dropout due to somatic hypermutation.
Aims: Our goal was to develop an NGS assay based on AMP that would enable IR characterization utilizing a minimal set of unidirectional GSPs and to reduce amplification bias through the use of MBC adapters.
Methods: Upon developing our AMP-based NGS assay, we validated its quantitative reproducibility and sensitivity using mRNA isolated from PBMCs of healthy donors, B-cell chronic lymphocytic leukemia donors and formalin-fixed paraffin-embedded (FFPE) tissue.
Results: We developed the AMP-based NGS assays, Immunoverse™ IGH and TCR, for B-cell and T-cell receptor sequencing, respectively. Both assays demonstrated high reproducibility between replicates with quantitative clone tracking down to 0.01%. The ability to determine isotype, clonotype and IGHV mutational status in a single assay was demonstrated. Preliminary TCR assay data indicates that CDR3 sequence capture is possible from FFPE tissue with clonotype calling being driven by input quantity, T-cell content, and, to a lesser degree, mRNA quality.
Summary/Conclusions: AMP-based NGS with MBC quantification and error-correction is a powerful method to characterize the immune repertoire.

E1091

SYNERGISTIC ANTITUMOR IMMUNITY BY DENDRITIC CELLS IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN A MURINE MYELOMA MODEL

S.-H. Jung[1,*], S. Yang[2], H.-J. Lee[2], M.-C. Vo[2], T.J. Lakshimi[2], H.-J. Kim[1], J.-J. Lee[1]
[1]Department of Hematology-Oncology, [2]Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: Pomalidomide (Pom) plus dexamethasone (Dex) could be considered one of the new treatment options in patients with relapsed and/or refractory multiple myeloma (MM). Recently, several diverse agents would be combined to improve the therapeutic efficacy of immunotherapy.
Aims: In this study, we investigated the preclinical efficacy of combined therapy with dendritic cells (DCs) and Pom-Dex in a murine myeloma model.
Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) Pom + Dex, and 4) DCs + Pom + Dex. After vaccination, preclinical and *in vitro* immunological responses were evaluated.
Results: Among four treatment groups, DC combined with POM and DEXA strongly inhibited tumor growth, compared with other groups. *in vitro* immunological analyses revealed that these enhanced anti-tumor effects were closely associated with the decrease of regulatory cell populations, such as regulatory T cells (Tregs) and type 2 macrophages (M2), and the increase of effector cell populations, including activated CD4 T cells, and type 1 macrophages (M1), accompanied with the activation of cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells in the splenocytes from vaccinated mice.
Summary/Conclusions: This study suggested thay DC combined with POM and DEXA synergistically enhance the anti-tumor immunity in a murine myeloma model, by skewing immuno-suppressive status toward immuno-supprotive status in tumor microenvironment.

ALTERATIONS IN T-CELL SUBPOPULATIONS AFTER CO-CULTURING WITH MSCS DERIVED FROM DIFFERENT DONORS

N. Kapranov[1,*], Y. Davydova[1], I. Galtseva[1], N. Petinati[1], N. Drize[1], L. Kuzmina[1], E. Parovichnikova[1], V. Savchenko[1]
[1]Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Study of interactions between lymphocytes and mesenchymal stromal cells (MSCs) *in vitro* revealed increase of HLA-DR expression on T-cells after co-cultivation with some MSCs samples. On lymphocytes derived from one donor the elevation of HLA-DR was observed after co-cultivation with half of MSCs samples (group A), on the others the HLA-DR expression level did not change (group B). MSCs were divided into two groups based on HLA-DR rise on lymphocytes. Study of T-cell subpopulations after interactions with MSCs could explain ineffectiveness of some MSCs as an immunomodulating agent in clinical applications.
Aims: The aim of the study was to discriminate variations in T-cell subpopulations, co-cultured with MSCs from two groups.
Methods: MSCs were isolated from bone marrow of 13 donors for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^5 cells per flask, and then 10^6 allogeneic lymphocytes from single donor were added to all MSCs cultures. For lymphocytes activation 5mg/ml phytohemagglutinin (PHA) was added to half of these cultures. Lymphocytes were removed from MSCs. Than MSCs were removed from the bottom of the flask by trypsin and expression of HLA-DR on their surface was measured by flow cytometry. Activation markers CD25, CD38, CD69, HLA-DR and PD-1 were studied by flow cytometry as well as distribution of naïve and effector T-cells were analyzed on 4th day of cultivation. $p<0.05$ was considered statistically significant; all data are presented as medium ± SEM.

Table 1.

Table. Subpopulations of lymphocytes that differ between group A and group B.

Subtypes of T-cells	Subpopulation	Control samples without MSCs	Group A	Group B
Non-activated lymphocytes 4 days				
CD4	HLA-DR+	8.46±1.0%	20.4±1.7%*	7.4±0.4%
	EM	29.8±1.6%	20.2±1.2%*	16.6±0.9%*
	TM	0.9±0.2%	1.2±0.2%	0.34±0.02%*
	CD127-/CD25-	17.4±5.1%	18.9±1.9%	12.4±2.0%*
Activated lymphocytes 4 days				
CD4	HLA-DR+	90.3±1.6%	72.1±3.6%	29.7±9.3%*
	CM	64.1±9.5%	53.4±2.7%	32.7±5.5%*
	TM	0.9±0.3%	1.8±0.2%	0.27±0.13%
	PD-1+	65.4±5.7%	44.5±5.6%*	17.6±3.2%*
CD8	HLA-DR+	89.0±2.5%	76.2±4.6%	35.0±13.1%*
	CM	57.7±9.3%	35.8±2.6%*	15.1±6.0%*
	EM	6.8±1.1%	16.4±2.3%*	10.1±1.5%
	TE	8.6±2.1%	6.2±0.7%	14.1±2.8%*
	PD-1+	53.3±7.8%	23.4±3.5%*	10.6±2.6%*

* indicates data in group A or B that significantly differs from control samples

Results: Expression of HLA-DR on lymphocytes after 4 days of cultivation without MSCs did not change compared to 1st day. When lymphocytes were co-cultured with some MSCs samples expression of HLA-DR was higher. Elevated percentage of HLA-DR positive cells correlates between CD4+ and CD8+ cells (R^2=0.932). Thus samples of MSCs were divided into two groups: in group A proportion of HLA-DR lymphocytes were 3 times greater than in group B. Subpopulations of lymphocytes co-cultured with MSCs from group A and B were compared. Subpopulations which significantly differed between groups A and B are presented in the table. In lymphocytes co-cultured with MSCs there were higher number of naïve cells compared to control (47.4±3.5% and 54.9±2.0% for group A and B *vs* 36.9±1.4% for lymphocytes cultured without MSCs, $p<0.001$). Group B showed lower number of EM and TM cells. Differences between groups were more pronounced when lymphocytes were activated. In group B proportion of HLA-DR CD4+ and CD8+ cells was significantly lower, compared to group A and control samples. At the same time the number of CM and PD-1+ CD4+ cells was lower in group B, but number of TE was increased. Investigation of HLA-DR expression on MSC after co-culturing with lymphocytes showed higher level of fluorescence signal (MFI) in group A then in group B (635±130 *vs* 289±18, p=0,03). These data indicated that MSCs from group A had become more immunogenic after interaction with lymphocytes and could not show immunomodulating properties in same way as MSCs from group B.
Summary/Conclusions: The immunomodulatory properties of MSCs depend on the donor. This could explain why administration of MSCs is not always successful. Preliminary study of MSCs prior to their administration may be used to predict their efficiency in the future.

GRANULOCYTE COLONY STIMULATING FACTOR AND ERYTHROPOIETIN ENTERALLY GIVEN FOR NEONATES RECOVERING FROM GIT SURGERIES: RANDOMIZED CONTROLLED TRIAL

G. Gad[1], R. El-Farrash[1,*], H. Abdelkader[2], S. Fahmy[3]
[1]Pediatrics Department, [2]Pediatric Surgery Department, Faculty of Medicine-Ain Shams University, [3]Ministry of Health, Cairo, Egypt

Background: Feeding intolerance is a common problem among neonates recovering from surgery for congenital abnormalities of the gastrointestinal tract (GIT) such as small bowel atresia, omphalocele or gastroschisis. Feeding intolerance is a multifactorial process, but one of the important reasons is congenital maldevelopement of the small bowel villi. Disuse atrophy of the small bowel mucosa following several days of post-operative enteral fasting is one factor that can contribute to feeding intolerance. The human fetus swallows over 200 ml/kg/day of amniotic fluid and such swallowing is essential for normal small bowel development. Growth factors found in the amniotic fluid have been shown to promote proliferation of fetal intestinal cells. These growth factors include epidermal growth factor, granulocyte colony stimulating factor (G-CSF) and erythropoietin (EPO). We postulated that infants recovering from surgeries for congenital obstructive bowel abnormalities could be provided with physiologic quantities of recombinant human G-CSF and EPO by the intermittent orogastric or nasogastric administration of 20 mL/kg/day of sterile isotonic solution that contained cytokine concentrations comparable to what they would have ingested from amniotic fluid in utero.
Aims: is to test a hypothesis suggesting that feeding tolerance could be improved in neonates recovering from surgeries for congenital obstructive bowel abnormalities by enterally administering recombinant human G-CSF and EPO included within simulated amniotic fluid solution.
Methods: This double-blinded randomized controlled clinical trial was conducted on 40 neonates recovering from GIT surgeries for congenital bowel abnormalities. Hemodynamically unstable babies, and those with any contraindication to enteral feeding were excluded. Neonates were randomly divided postoperatively into 2 groups; 20 neonates received the test solution (called Simulated Amniotic Fluid-like solution given Enterally; SAFE); 20 neonates enterally received distilled water (control). Treatment was started postoperative and the test solution (or distilled water) was discontinued when enteral intake reached 100cc/kg/day. Feeding tolerance and adverse effects of treatment (if any) were assessed.
Results: All the studied neonates tolerated the received solution well without side effects that could be attributed to its intake. The study group showed better feeding tolerance as reflected by earlier achievement of 50, 100, 120 and full enteral feeds with higher enteral caloric intake 7 days after SAFE administration and higher rate of weight gain ($p<0.05$). No significant increase was found in the level of WBCs count, hemoglobin and hematocrit values either pre-initiation or 7 days after administration of SAFE ($p>0.05$).
Summary/Conclusions: This study provides further insights on the improvement of neonatal outcomes and help to decrease morbidities from post-operative malnutrition and feeding intolerance. Enteral administration of rhG-CSF and rhEPO may play a critical role in preventing villous atrophy, thereby, reducing feeding intolerance in neonates recovering from surgeries for congenital bowel abnormalities.

GENE EDITING OF HUMAN HEMATOPOIETIC PROGENITORS TO CORRECT PYRUVATE KINASE DEFICIENCY

S. Fañanas-Baquero[1,2,*], I. Orman[1,2], A. Gouble[3], R. Galetto[3], L. Poirot[3], J.A. Bueren[12], O. Quintana-Bustamante[1,2], J.C. Segovia[1,2]
[1]Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas/Centro de Investigación Biomédica en Red de Enfermedades Raras (CIEMAT/CIBERER), [2]Advanced Therapies Unit, Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD, UAM), Madrid, Spain, [3]CELLECTIS, Paris, France

Background: Pyruvate Kinase Deficiency (PKD) is a rare erythroid metabolic disease caused by mutations in the *PKLR* gene which encodes the erythroid specific Pyruvate Kinase (RPK) enzyme. The defective enzyme fails to produce normal ATP levels and consequently, erythrocytes from PKD patients show an energetic imbalance and are susceptible to hemolysis. Site-specific hematopoietic stem cell gene therapy would be the safest approach to treat PKD patients. In this study, different gene editing approaches have been explored to correct PKD, either by the Knock-in of a *PKLR* cDNA sequence in the second intron of the gene, or by the site-specific correction of specific mutations.
Aims: In the Knock-in system, that previously showed to correct the PKD phenotype of PKD-iPSC lines, a recombination matrix carrying codon optimized exons 3-11 of the *PKLR* cDNA and a puromycin selection cassette was inserted in the second intron of the *PKLR* gene assisted by TALEN nucleases.
Methods: Thus, the therapeutic matrix together with specific TALENs as DNA plasmid or mRNA, for the second intron of PKLR were electroporated in purified $CD34^+$ cells from healthy cord bloods. Cells were then expanded and puromycin selected to enrich the population for gene edited ones.

Results: Although a high toxicity and low efficiency were observed with the electroporation technique used, up to 96% colony forming units showed the specific integration. Experiments directed to improve efficacy and reduce toxicity were then conducted. A high percentage of gene edited HPCs were detected by shortening the cell expansion and puromycin selection periods. Importantly, gene edited HPCs were detected after infusion in immunodeficient (NSG) mice. More recently, site-specific correction has been developed aiming at the correction of PKD patient's specific mutations.
Summary/Conclusions: Overall, we showed that gene editing in engraftable HPCs is feasible, although the efficiency of the procedure should be further improved prior to consideration of these strategies in the clinic.

BLAST KINETICS AFTER NON-ENGRAFTING HAPLOIDENTICAL MICROTRANSPLANTATION IN PATIENTS WITH REFRACTORY ACUTE MYELOID LEUKEMIA

Z. Emarah[1,2,*], S. Shamaa[1,2], M. El-Zaafarany[1,2], N. Essa[3,4], M. Khalaf[5]
[1]Medical Oncology Unit, Oncology Center, Mansoura University, [2]Medical Oncology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, [3]Clinical Hematology Unit, Oncology Center, Mansoura University, [4]Clinical Hematology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, Mansoura, [5]Clinical Hematology Department, Hematology and Oncology Hospital, Maadi Armed Forces Medical Compound, Cairo, Egypt

Background: Multiple trials have showed that granulocyte colony-stimulating factor (G-CSF) –mobilized donor peripheral-blood stem cells (GPBSCs) based on allo-graft can be effective in mediating graft-versus-leukemia (GVL) effects and promote hematologic recovery without triggering of acute GVHD.
Aims: To analyze the safety and efficacy of non-engraftment haploidentical cellular therapy for patients with refractory acute myeloid leukemia by assessment of bone marrow blast and hematopoietic cells percent kinetics.
Methods: Seven patients (4 males 57.1%, 3 females 42.9%) with refractory acute myeloid leukemia were enrolled into this Phase I/II study. They were treated with chemotherapy including fludarabine 30mg/m^2, cytarabine 1gm/m^2, etoposide 100mg/m^2, endoxan 750mg/m^2 followed by infusion of haploidentical unmanipulated GPBSCs 24 hour after last chemotherapy infusion. Morphologic assessment of bone marrow blast kinetic by bone marrow aspiration conducted before therapy, D14 and D30 after therapy. Hematopoietic cells percent kinetics (Hematologic recovery) was assessed by Complete blood count every day till Day 40.

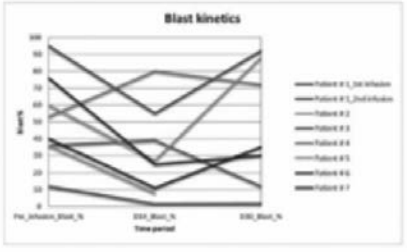

Figure 1. Blast kinetics, pre-infusion, D14 and D30 blast % for individual patients.

Figure 1.

Results: At day +30, 6 patients were evaluable for response and one patient had died. One patients out of 7 showed PR, then developed CR after a second microtransplantation and the patient who died showed PR at D14 marrow evaluation (8% blast). So collectively objective response rate was 28.6%. The patient who developed CR was consolidated with an HLA-matched sibling transplant at day +75 from the 1st microtransplantation (day +50 from 2nd microtransplantation).Three patients attain neutrophil recovery with median time 29 (range, 13-40) days, while the other four patient did not. Two patients attain platelet recovery with median time 34.5 (range, 29-40) days, while the other five patient did not. The cellular therapy did not elicit statistically significant changes in bone marrow blast% over time, F(2, 10)=1.558, p=.258, partial η2=.238., with bone marrow blast% decreasing from pre-infusion blast% (M=60%, SD=22.4%) to D14 blast% (M=39.5%, SD=24.47%) then increased to D30 blast% (M=54.8, SD=33.5%), in that order. Less than four previous chemotherapy, fludarabine-free previous chemotherapy and response naïve patients are the factors associated with good response to microtransplantation. There was a strong positive correlation between patient age (statistically significant), CR1 duration (statistically non-significant) and blast% at D30, r=.842 and .693, p=.036 and p=.307 respectively. There was a moderate negative non-statistically significant correlation between CD34+ cell dose and blast% at D30, r=-.498, p=.315.
Summary/Conclusions: The use of G-CSF primed halo-identical microtransplantation appears to be a biologically active therapy in patients with refractory AML, especially in patients received less than four previous chemotherapy, fludarabine-free previous chemotherapy, response naïve and young age patients.

E1096

ALTERATIONS IN T-CELLS SUBPOPULATIONS AFTER CO-CULTIVATION WITH MULTIPOTENT MESENCHYMAL STROMAL CELLS

Y. Davydova[1,*], N. Kapranov[1], I. Galtseva[1], N. Petinati[1], N. Drize[1], L. Kuzmina[1], E. Parovichnikova[1], V. Savchenko[1]
[1]Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Lymphocyte population depends on immunological state of organism and varies in different diseases and during treatment. Multipotent mesenchymal stromal cells (MSCs) are widely used for cell therapy due to their immunomodulatory properties. Administration of MSCs is not always effective. Immunomodulatory properties of MSCs could be induced by different cytokines, *e.g.* IFN-γ. After injection MSCs interact with activated and non-activated lymphocytes. Changes in lymphocytes subpopulations characterize the influence of MSCs on immunological state.
Aims: The aim of the study was to determine the distribution of naïve and effector cells in lymphocytes co-cultured with MSCs.
Methods: MSCs were derived from bone marrow of 13 donors (7 male and 6 female aged 22 to 62 years, median 27 years). MSCs were co-cultured with allogeneic lymphocytes in a ratio of about 1:10 for 4 days and their basic properties were analyzed over time. Lymphocytes were activated by adding to the culture medium 5mg/ml of PHA (PHA-lymphocytes). Some MSCs were treated for 4 hours with 500 U/ml IFN-g (gMSCs). Activation markers CD25, CD38, CD69, HLA-DR and PD-1 were studied by flow cytometry as well as distribution of naïve and effector cells were analyzed on 1st, 2nd, 3rd and 4th days of cultivation.
Results: By the fourth day of incubation the proportion of naive CD4+ cells reduced by 30% (from 47.5±3.0% to 32.8±3.3%) in cultured lymphocytes. It did not happen in lymphocytes co-cultured with MSCs and gMSCs (p=0.001). At the same time in cultured lymphocytes to the fourth day the number of CD4+ effector memory cells increased in 1.8 times from 19.5±1.9% to 34.6±4.2%, which did not occur when co-cultured with both MSCs and gMSCs (p=0.001). Thus, co-culturing with MSCs or gMSCs prevented naive T-lymphocytes transition into effector cells. The proportion of CD4+/PD-1+ cells increased from 8.2±1.1% to 10.9±0.7% by the 4th day of cultivation. When co-cultured with MSCs and gMSCs the proportion of these cells did not change (p=0.0125). The proportion of HLA-DR+ both on CD4+ and CD8+ cells in lymphocytes remained unchanged for 4 days. When co-cultured with MSCs and gMSCs for 4 days there was a consistent increase in the proportion of CD4+/HLA-DR+ (6.1±0.7% to 15.6±1.1%, p=0.005) and CD8+/HLA-DR+(from 9.7±0.8% to 26.0±3.7%, p=0.024). So allogeneic MSCs induced peptide presentation on lymphocytes. The proportion of CD4+ central memory cells increased in PHA-lymphocytes from 37.4±4.4 at 1st day to 68.2±6.5 at 4th day. MSCs inhibited this increase - the proportion CD4+ central memory cells increased from 24.4±2.7% to 46.6±4.5% (p=0.047). Thus the interaction of PHA-lymphocytes with MSCs inhibited their activation and preserved naïve state.
Summary/Conclusions: The composition of lymphocyte population changes during cultivation. The proportion of naive cells reduced, while the number of effector cells and the proportion of PD-1+ increased, indicating lymphocyte activation probably due to the presence of xenogeneic serum in the culture medium. Co-cultivation with MSCs maintained lymphocytes in not activated state. The interaction of activated lymphocytes with MSCs inhibits their activation and preserves naïve state. IFN-γ priming did not enhance MSCs inhibitory effect on lymphocyte activation. It is shown that MSCs both support naïve lymphocyte condition and have an inhibitory effect on their activation.

OPTIMIZATION OF TRANSDUCTION CONDITIONS WITH GMP LIKE LENTIVIRAL VECTORS FOR THE GENE THERAPY OF PYRUVATE KINASE DEFICIENCY

S. Navarro[1,2,*], O. Quintana-Bustamante[1,2], C. Trigueros[3], M. Villanueva[1,2], S. López-Manzaneda[1,2], J.A. Bueren[1,2], J.C. Ramirez[3], J.C. Segovia[1,2]
[1]Unidad Mixta de Terapias Avanzadas, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, [2]Hematopoietic Innovative Therapies, CIEMAT/CIBERER, Madrid, [3]VIVEbioTECH, San Sebastian, Spain

Background: Pyruvate kinase deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD is the most common erythroid inherited enzymatic defect causing chronic nonspherocytic hemolytic anemia. PKD is associated with reticulocytosis, splenomegaly and hepatic iron overload, and may be life-threatening in severely affected patients. To-date, allogeneic bone marrow transplant represents the only curative treatment for severely affected patients but has been employed infrequently. Splenectomy confers reduced transfusion-dependence in many patients, but 10-15% of PKD patients remain transfusion-dependent despite splenectomy, which confers increased lifelong susceptibility to systemic infections. Preclinical gene therapy studies conducted in pyruvate kinase deficient mice have shown the safety and the efficacy of a new CPcoRPKW-17 therapeutic lentiviral vector that has been granted orphan drug designation (EMA: EU/3/14/1330; FDA: DRU-2016-5168).

Aims: In order to develop a gene therapy clinical trial for PKD we are optimizing transduction procedures compatible with a clinical application
Methods: Using a GMP-grade lentiviral vector production according to manufacturing process of the CMO VIVEbioTECH (www.vivebiotech.com) using a solid phase bioreactor iCLELLis. These viral batches have been tested for transduction efficiency in healthy cryopreserved cord blood CD34+ cells comparing different viral concentration and one or two transduction rounds.
Results: Increased doses of virus concentration revealed, as expected, increasing levels of transduction that ranged 40-90% both by scoring transduced colony forming units and by flow cytometry analysis in hematopoietic progenitors maintained for 15 days in liquid culture. Analysis of vector copy number (VCN) by qPCR ranged from 0.5 to 3 VCN/cell, demonstrating good transduction efficiency, compatible with a clinical application. Two cycles of transduction showed an increased level of transduction at limiting concentrations of the viral vector, improving the VCN up to 2-fold.
Summary/Conclusions: Transduction optimizations are being carried out in order to reduce the amount of viral vector needed to achieve optimal transduction efficiencies.

E1098

INTERACTION OF MULTIPOTENT MESENCHYMAL STROMAL CELLS WITH LYMPHOCYTES REDUCES THEIR IMMUNO PRIVILEGED PROPERTY
N. Petinati[1,*], N. Kapranov[2], Y. Davydova[2], I. Galtseva[2], M. Bakshinskayte[3], N. Drize[1], L. Kuzmina[4], E. Parovichnikova[4], V. Savchenko[5]
[1]Physiology of Hematopoiesis Lab., [2]Lab. of Immunophenotyping, National Research Center for Hematology, [3]Biology Department, sub Department Immunology, Moscow State University im. Lomonosov, [4]Bone Marrow Transplantation Department, [5]National Research Center for Hematology, Moscow, Russian Federation

Background: Multipotent mesenchymal stromal cells (MSCs) are widely used for cell therapy of autoimmune diseases and graft-versus-host disease. MSCs have long been reported to be hypoimmunogenic or 'immune privileged'. The treatment of MSCs with interferon-g (IFNg) increases their immunomodulating properties, but induce HLA-DR expression on their surface. When administered intravenously MSCs interact with activated and non-activated lymphocytes. It is impossible to follow the fate of MSCs in the recipient's organism. The only way to study the changes in the properties of MSCs after intravenous administration is *in vitro* model.
Aims: The aim of the study was to investigate the properties of MSCs after interaction with lymphocytes.
Methods: MSCs were isolated from 13 bone marrow samples used for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^5 cells per flask and a day later 500 units/mL of IFN-g were added for 4 hours to half of the cultures (gMSCs). Some cultures were seeded with 10^6 allogeneic lymphocytes, to half of these cultures 5mg/ml phytohemagglutinin (PHA) was added for lymphocytes activation (PHA-Lymphocytes). For each of the MSCs cultures the mean fluorescent signal intensity level (MFI) of CD90 PE, CD54 APC, HLA-DR APC was measured. Relative expression level (REL) of *IDO1, CFH, PTGES, IL6, CSF1, ICAM-1* was analyzed in MSCs by RT-PCR. MFI and REL were investigated on the 1st, 2nd, 3rd and 4th days of cultivation.
Results: HLA-DR expression on MSCs increased when co-cultured with lymphocytes and after IFNg treatment. PHA-lymphocytes induced HLA-DR expression significantly greater than IFNg licensing. IFNg increased the viability of MSCs when co-cultured with lymphocytes. Immunomodulating properties of MSCs were amplified both after IFNg priming and interaction with lymphocytes, so did not dependent on IFNg source (exogenous or secreted by lymphocytes). The elevated expression ICAM1 on manipulated MSCs may indicate an increase in their adhesive properties. IFNg treatment and interaction with lymphocytes induced in MSCs the increase in relative expression level (REL) of factors involved in immunomodulation (*IDO1, CFH, PTGES, IL6, CSF1*).
Summary/Conclusions: The data suggest that IFNg treatment enhances the immunomodulatory effects of MSCs in the case of intravenous injection into the body. Interaction with lymphocytes of the recipient causes the same change in the properties of MSCs as their pre-treatment of IFNg. However, this treatment stabilizes the MSCs, while maintaining their viability. Based on the results of this work it can be recommended to use: 1. autologous or obtained from the donor hematopoietic cells MSCs; 2. the short-term pre-treated with IFNg MSCs for cell-based therapy for immune modulation in order to increase MSCs survival.

SPECIFICATION OF MURINE HEMOGENIC ENDOTHELIAL HEMATOPOIETIC PRECURSORS CEASES ABRUPTLY BY E10.25 AND CONSTITUTES A FUNCTIONALLY HETEROGENEOUS POPULATION
M. Ganuza Fernandez[1,*], B. Hadland[2,3], A. Chabot[1], G. Kang[4], I. Bernstein[2,3], S. McKinney-Freeman[1]
[1]Experimental Hematology, St. Jude Children's Research Hospital, Memphis, [2]Clinical Research Division, Fred Hutchinson Cancer Research Center, [3]Department of Pediatrics, University of Washington School of Medicine, Seattle, [4]Department of Biostatistics, St. Jude Children's Research Hospital, Memphis, United States

Background: Hematopoietic stem cells (HSCs) arise from hemogenic endothelial (HE) precursors between embryonic day 10.5 (E10.5) and E12.5 of murine development, primarily in the aorta-gonad-mesonephros (AGM) region and the umbilical (UA) and vitelline arteries (VA). The window of specification of HE has not yet been defined in any mammalian system.
Aims: To determine the precise window of specification of HE hematopoietic precursors and interrogate at the single cell level their functional heterogeneity.
Methods: Dams pregnant with *Cdh5+/ERT2-CreROSA26Confetti/+*embryos were treated with tamoxifen (TAM) at E7.5, E8.5, E9.5, E10.5 or E11.5. Here, TAM induces the permanent and random labeling of endothelial cells and their progeny with one of the *Confetti* allele fluorescence reporters (YFP, GFP, CFP or RFP). The blood of resulting adult *Cdh5+/ERT2-CreROSA26Confetti/+*offspring was then examined for the presence of *Confetti*+ cells by flow cytometry. Clonal *ex vivo* assays: VE-Cadherin+CD45- cells, which contain HE, were isolated by FACS from E9.5, E10.5 or E11.5 embryos and co-cultured at limiting dilution *ex vivo* with either OP9 stromal cells (OP9) or AGM-derived endothelial cells engineered to express Myr-AKT (AA-ECs), which both support hematopoietic output from HE *ex vivo*. Co-cultures were scored for hematopoietic colony formation, which were then analyzed for hematopoietic re-plating activity and by flow cytometry for hematopoietic cell surface markers.
Results: To estimate the temporal window of TAM activity, CD45.2+ *ROSA26ERT2-Cre/Confetti* bone marrow (BM) cells were transplanted into CD45.2+CD45.1+ recipients treated with TAM three, two, one or zero days before transplant. Only the PB of recipients treated on the same day of transplant showed *Confetti*+cells, indicating that TAM actively labels cells for less than 24 hours. Analysis of 10 weeks old *Cdh5+/ERT2-CreROSA26+/Confetti* mice revealed that only mice exposed to TAM *in utero* at E8.5 and E9.5 had *Confetti*+ blood. Thus, specification of HE begins at E8.5 and is complete by E10.5. Next, E11.5 AGMs isolated from CD45.2+ *Cdh5+/ERT2-CreROSA26+/Confetti* embryos exposed to TAM at E10.5 were cultured as explants for three days under conditions that preserve ongoing HSC specification from HE, dissociated, and then transplanted into CD45.2+CD45.1+ mice. Remarkably, although the CD45.2+ chimerism was high (≈80%) in the blood of recipients, all CD45.2+ blood was negative for the *Confetti* label, further indicating that HE recruitment is complete by E10.5 and cannot be reactivated during explant culture. Limiting dilution co-culture of E9.5, E10.5, and E11.5 VE-Cadherin+CD45- endothelium revealed the frequency of functional HE to be 0.1, 1.1 and 0.19% at these time-points, respectively. Phenotypic analysis of primary hematopoietic colonies revealed heterogeneity in the hematopoietic output of individual HE, with only 9% of colonies producing phenotypic HSCs in AA-EC co-cultures. These data suggest the presence of HE precursors with distinct functional output or the existence of a continuum of HE at different stages of maturation.
Summary/Conclusions: We have defined the window of mammalian HE specification. The abrupt loss of ongoing HE recruitment at E10.25 suggests an active mechanism that terminates this process. We also observed large phenotypic and functional variability amongst individual HE precursors examined throughout ontogeny.

E1100

C-TYPE LECTIN-LIKE RECEPTOR 2 SPECIFIES A FUNCTIONALLY DISTINCT SUBPOPULATION OF MEGAKARYOCYTE-BIASED LONG-TERM HEMATOPOIETIC STEM CELLS
T. Kumode[1,*], H. Tanaka[1], R. Fujiwara[1], K. Sano[1], K. Serizawa[1], Y. Taniguchi[1], S. Rai[1], I. Matsumura[1]
[1]Hematology and Rheumatology, Kindai University Faculty of Medicine, Osaka, Japan

Background: Recent studies have supported the model in which hematopoietic stem cell (HSC) compartment consists of functionally distinct subsets with discrete self-renewal and differentiation potentials. However, their immunophenotypes and the functional diversities remain poorly understood. We previously reported that the authentically identified HSC population includes a subset of cells expressing the C-type lectin-like receptor 2 (CLEC2), which efficiently give rise to megakaryocyte progenitors (MkPs) and megakaryocytes bypassing the pathway from common myeloid progenitor (CMP) to megakaryocyte/erythrocyte progenitor (MEP) (21th Congress of EHA, # P356, 2016).

Aims: In this study, we analyzed *in vivo* dynamics of CLEC2^{high} HSCs to clarify their functional roles in adult hematopoiesis.
Methods: In this experiment, we defined Lin$^-$Sca1$^+$Kit^{high} CD150$^+$CD34$^-$ cells as HSCs and Lin$^-$Sca1$^-$Kit$^+$CD150$^+$CD41$^+$ as MkP, respectively. We performed transplantation assays using HSCs isolated from EGFP transgenic (CAG-EGFP) mice to trace donor-derived HSCs and their progeny excepting enucleated erythrocytes. In reconstitutional analysis, 5x10^{2}EGFP$^+$CLEC2^{high} and CLEC2^{low} HSCs were transplanted into lethally irradiated mice, respectively. Chimerism and lineage distribution of donor-derived cells were evaluated periodically by tracing EGFP. Secondary transplantation was performed by transferring 1x10^7 BM cells from the recipient mice 16 weeks after the 1st transplantation.
Results: Bone marrow analysis revealed that both EGFP$^+$CLEC2^{high}and CLEC2^{low} donor-derived HSC populations were detected for up to 12 weeks after transplantation. Also, these subsets were capable of generating all lineages of cells in transplanted mice. Interestingly, CLEC2^{high} HSCs generated CLEC2^{low} HSCs in the recipient mice as observed in the steady-state BM, and vice versa. Consistent with these reciprocal transition, both types of HSCs could effectively reconstituted hematopoiesis in the secondary recipients. However, CLEC2^{high} HSCs showed significantly reduced repopulating activity than CLEC2^{low} cells, especially at 12 weeks after transplantation (mean of EGFP$^+$ HSC proportion in the primary recipients with CLEC2^{high} HSCs *vs* CLEC2^{low} HSCs (each n=5): 21.1% *vs* 66.1% at 4 weeks (p=0.054); 2.14% *vs* 48.3% at 12 weeks (p<0.05). In addition, the recipient mice transplanted with CLEC2^{low} HSCs kept high chimeric levels of EGFP$^+$ CMP and MEP, while these levels decreased in the recipients with CLEC2^{high} HSCs. On the other hand, CLEC2^{high} HSCs yielded 2.8-fold more MkPs than CLEC2^{low} HSCs in short term grafts (1 to 2 weeks after transplantation) (p<0.05). Consistent with this finding, CLEC2^{high} HSCs yielded more CD41$^+$ platelets than CLEC2^{low} HSCs by 6.0-fold at 1 week after transplantation (p<0.05), which peaked 10 weeks earlier than in CLEC2^{high}-recipient mice. These platelets yielded through the transient expansion of MkPs were detected at a certain level 12 weeks after transplantation. Furthermore, treatment with fostamatinib (R788), a Syk kinase inhibitor that is an indispensable component for CLEC2 signaling, blocked more potent and rapid megakaryopoiesis in the CLEC2^{high}-recipients, indicating that CLEC2 signaling is essential for rapid and enhanced megakaryopoiesis from CLEC2^{high} HSCs.
Summary/Conclusions: Here, we showed that CLEC2 expression on HSCs demonstrates their oscillation for serving as a potent source of megakaryopoiesis, and found that CLEC2/Syk signaling would be involved in differential regulation between CLEC2^{high} and CLEC2^{low} HSC subtypes.

E1101

PRE-TRANSPLANT DEFECTS OF BONE MARROW ENDOTHELIAL CELLS MAY CAUSE THE OCCURRENCE OF POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y. Kong[1], M.-M. Shi[1,2,*], Y. Song[1,2], Y.-H. Chen[1], T.-T. Han[1], Y.-Q. Sun[1], Y. Wang[1], X.-H. Zhang[1], L.-P. Xu[1], X.-J. Huang[1,2]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Poor graft function (PGF) is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). PGF is defined as complete donor hematological chimerism with no residual or recurrent leukemia, but a hypo- or aplastic bone marrow (BM) with 2 or 3 of the following: (1) neutrophils ≤0.5×10^9/L; (2) platelets ≤20×10^9/L; and/or (3) hemoglobin concentration ≤70 g/L for at least 3 consecutive days after day +28 post-HSCT. The exact pathogenesis of PGF remains unclear. Mouse studies suggest that endothelial progenitor cells (EPCs), one of the major components in BM vascular microenvironment, modulate the proliferation, self-renewal and differentiation of hematopoietic stem cells(HSCs). In this regard, we previously reported that PGF patients had impaired BM EPCs post-HSCT (*BBMT* 2013; *BMT* 2016). Moreover, we recently reported that the impaired BM EPCs post-HSCT, which could be quantitatively and functionally improved by atorvastatin in vitro, may induce the occurrence of PGF (*Blood, 2016*). However, whether the BM EPCs in subjects with PGF are impaired pre-HSCT and the reconstitution kinetics of BM EPCs post-HSCT remains to be elucidated.
Aims: To investigate whether the BM EPCs in subjects with PGF are impaired pre-HSCT. To compare the reconstitution kinetics of BM EPCs, HSCs and their ROS levels in subjects with PGF and good graft function (GGF) post-HSCT.
Methods: A total of 115 patients who will receive allo-HSCT were prospectively recruited and randomly selected as training group (n=32) and validation group (n=83). The percentage of BM CD45-CD34+VEGFR2+ EPCs, CD34+ HSCs, and reactive oxygen species (ROS) levels in EPCs and HSCs were evaluated in all of the enrolled patients pre-HSCT by flow cytometry. Furthermore, 59 patients were monitored for the frequency and ROS levels of BM EPCs and HSCs at +1, +2 month post-HSCT by flow cytometry. In order to identify risk factors for PGF, pre-HSCT risk factors with a *P*<0.10 on univariate logistic analysis were included in the multivariate logistic regression analysis, and factors with a *P* <0.05 were considered independently associated with PGF.
Results: A total of 18 patients including 5 patients in training group (15.63%) and 13 subjects in validation group (15.67%) developed PGF post-HSCT. Both in training group and validation group pre-HSCT, significantly reduced percentage of BM EPCs were observed in PGF patients than those in GGF patients, whereas no significant differences were found in the percentage of BM HSCs between PGF and GGF patients. Meanwhile, similar ROS levels were demonstrated in BM EPCs and HSCs between PGF and GGF patients. Although there was no difference in transplanted CD34+ cell dose between the PGF and GGF groups, significantly lower percentages of BM EPCs and HSCs, whereas remarkably higher ROS levels were observed in BM EPCs and HSCs in PGF patients than those in GGF patients at +1 month and +2 month after allo-HSCT. Moreover, inverse correlations were observed between BM EPCs frequency and their ROS levels post-HSCT, as well as BM HSCs frequency and their ROS levels post-HSCT. Multivariate analyses revealed that the reduced BM EPCs and the disease status pre-HSCT were independent risk factors for the occurrence of PGF following allo-HSCT.
Summary/Conclusions: We identified that patients with impaired BM EPCs pre-transplant were at a high risk for the occurrence of PGF post-allotransplant. Moreover, persistent low percentage and high levels of ROS in post-transplant BM EPCs may hamper the hematopoietic reconstitution of engrafted donor HSCs in patients with PGF. Therefore, strategies to repair the impaired BM EPCs appear to be a promising therapeutic approach in patients with PGF after allo-HSCT.

EFFICIENT LYMPHOID DIFFERENTIATION OF HEMATOPOIETIC STEM CELLS REQUIRES CXCR4 DESENSITIZATION

C. Freitas[1], M. Wittner[2], J. Nguyen[1], V. Rondeau[1], J. Donadieu[3], F. Bachelerie[1], M. Espéli[1], F. Louache[2], K. Balabanian[1,*]
[1]INSERM U996, Clamart, [2]INSERM UMR_S1170, Villejuif, [3]Service d'Hémato-Oncologie Pédiatrique, Hôpital Trousseau, Paris, France

Background: The Warts, Hypogammaglobulinemia, Infections and Myelokathexis Syndrome (WS) is a rare immunohaematological disorder characterized notably by a chronic lymphopenia. It is mostly caused by inherited heterozygous autosomal gain-of-function mutations in *CXCR4*, which engender a distal truncation in the C-tail domain and lead to a desensitization-resistant receptor. Given that CXCR4 is widely expressed on non-hematopoietic cells and virtually on all leukocytes at multiple stages of development, one possibility could be that the WS-associated peripheral blood lymphopenia is a consequence of skewed production, differentiation or distribution of lymphocytes related to altered CXCR4-mediated signaling. Recently, we have been able to replicate the hematologic phenotype of WS using a knock-in mouse strain that harbors the WS-linked heterozygous *CXCR4^{S338X}* mutation causing a distal truncation of the last 15 residues of the C-tail domain (Balabanian et al., Blood, 2012). Mutant mice displayed lymphocytes with enhanced migration to Cxcl12, phenocopied severe lymphopenia and failed to maintain antibody titers after immunization (Biajoux et al., Cell Reports, 2016). First-line analyses of +/1013 mice suggested developmental defects at the pro/pre-B cell stage in the bone marrow (BM) and during the early double-negative stages of thymocyte maturation. However, whether impaired lymphopoiesis stems from an upstream cell-intrinsic hematopoietic defect remains to be established.
Aims: We took advantage of our relevant knock-in model and the access to blood samples from WS patients to investigate the impact of CXCR4 desensitization on BM and extra-medullary splenic hematopoiesis and recirculation of hematopoietic stem and progenitor cells (HSPCs).
Methods: The global hematopoietic development, including quiescence, cycling and survival properties of HSPCs, was examined in non-manipulated and BM-chimeric mice using flow-cytometric- and clonogenic-based assays. Cxcr4 expression and function were assessed using internalization, chemotaxis, *in vivo* homing and AMD3100-promoted mobilization experiments. Both multipotency and self-renewal abilities of HSPCs have been assessed using serial BM transplantation experiments. Immunophenotypic and clonogenic analyses of HSPCs were performed from blood samples of five WS patients and age-, sex-matched healthy donor volunteers.
Results: We showed that Cxcr4 desensitization is required for quiescence/cycling balance of murine short-term HSCs and their differentiation into multipotent (MPPs) and downstream lymphoid-biased progenitors (*i.e.* LMPPs and CLPs). Alteration in this negative feedback mechanism resulted in dramatic decrease of circulating HSPCs in five patients with WS. This was also evidenced in WS mice and mirrored by accumulation of HSPCs in the spleen, where enhanced extramedullary hematopoiesis occured.
Summary/Conclusions: Efficient Cxcr4 desensitization is critical for the lymphoid differentiation of HSPCs and its impairment is a key mechanism underpinning the lymphopenia observed in mice and likely in WS patients.

E1103

A SUBSET OF ADULT HSC DERIVES FROM GATA4-EXPRESSING PROGENITORS LOCATED IN THE PLACENTA AND LATERAL MESODERM OF MICE

A. Cañete Sánchez[1,*], R. Carmona[1], L. Ariza[1], M.J. Sánchez[2], A. Rojas[3], R. Muñoz-Chápuli[1]

[1]Animal Biology, Science Faculty, University of Málaga, Málaga, [2]centro Andaluz de Biología del Desarrollo, [3]andalusian Center of Molecular Biology and Regenerative Medicine, Sevilla, Spain

Background: GATA4 is a transcription factor expressed in mesoderm and endoderm during development. Members of the family such as GATA1-3, but not GATA4, are critically involved in hematopoiesis. An enhancer (G2) of the mouse *Gata4* gene directs its expression throughout the lateral mesoderm and the allantois, beginning at E7.5, becoming restricted to the septum transversum by E10.5, and disappearing by midgestation (Rojas et al., *Development*, 2005, 132:3405). Our previous work has shown that inactivation of *Gata4* using this $G2^{Cre}$ driver is lethal by midgestation (Delgado *et al.*, Hepatology, 2014, 59:2358). The anemia observed in the $G2^{Cre;}Gata4^{flox/flox}$ embryos was attributed to a failure in the expansion of the hematopoietic progenitors in the fetal liver. Interestingly, a small population of hepatic YFP^+ cells from $G2^{Cre;}R26R^{EYFP}$ embryos was positive for leukocyte and megakaryocyte markers, suggesting that a lineage of hematopoietic cells could derive from GATA4-expressing progenitors.
Aims: To study in our murine models the origin and properties of the hematopoietic lineage derived from progenitors expressing GATA4 under control of the G2 enhancer.
Methods: We analyzed hematopoietic organs of G2-$Gata4^{Cre;}R26R^{YFP}$ mice, adults and embryos, by flow cytometry, RT-PCR and confocal microscopy. Cells obtained from different tissues were cultured and transplanted to analyze *in vitro* and vivo potential.
Results: YFP+ cells represented about 20% of the hematopoietic system of adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. Adult YFP+ hematopoietic stem cells (Figure 1) constituted a long-term repopulating, transplantable population. Fetal YFP+ hematopoietic progenitors were much more abundant in the placenta than in the aorta-gonad-mesonephros area. These placental YFP+ progenitors were clonogenic in the MethoCult assay and fully reconstituted hematopoiesis in myeloablated mice (Cañete et al., *Haematologica*. doi: 10.3324/haematol.2016.155812. [Epub ahead of print]).

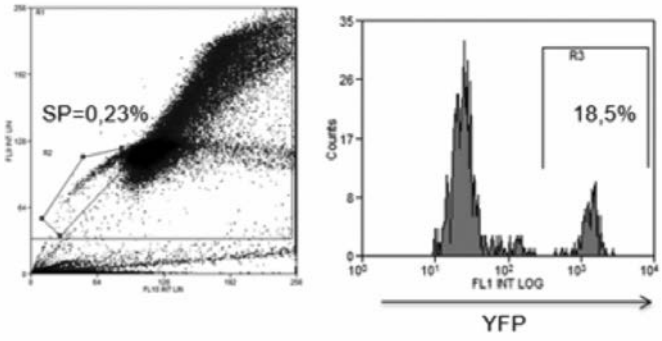

FIGURE 1: The side population of the bone marrow from $G2^{Cre;}$ $R26R^{EYFP}$ mice identified by Hoescht 22242 staining, which contains adult HSC, includes a fraction of YFP+ cells. (from Cañete et al., 2017)

Figure 1.

Summary/Conclusions: A lineage of adult hematopoietic stem cells in mice is characterized by the expression of GATA4 in their embryonic progenitors and probably by its extraembryonic (placental) origin. Both lineages basically showed similar physiological behavior in normal mice, but this finding raises a number of questions, for example: Does this hematopoietic stem cell subpopulation show a different response in physiopathological conditions? Does this subpopulation show a differential profile of gene expression? Does a similar heterogeneity exist in human HSCs? We are currently investigating the transcriptome of the G2-GATA4 linage HSC in order to answer these questions.

EXPLORING THE MECHANISM OF FOG1-DEPENDENT TRANSCRIPTIONAL REGULATION IN ERYTHROID CELLS

T. Fujiwara[1,*], K. Sasaki[1], K. Saito[1], S. Hatta[1], S. Ichikawa[1], M. Kobayashi[1], Y. Okitsu[1], N. Fukuhara[1], Y. Onishi[1], H. Harigae[1]
[1]Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: GATA-1 is a hematopoietic zinc-finger transcription factor, which controls the development of erythrocytes and megakaryocytes. Numerous proteins have been reported to be associated with GATA-1 to alter its activity. Among them, Friend of GATA-1 (FOG1), a nine-zinc finger protein, is expressed in a tissue-specific pattern that overlaps markedly with that of GATA-1. FOG1 is an essential coregulator of GATA-1 during hematopoiesis, which mediates transcriptional activation and repression of GATA-1 target genes; yet, the mechanisms by which FOG1 exerts its activating and repressing functions remain unknown.
Aims: We explored a novel role of FOG1 by forcibly expressing FOG1 in the human K562 erythroleukemia cells.
Methods: *FOG1* mRNA was cloned into Flexi HaloTag vector (Promega) and pBABE-puro retrovirus vector (Addgene), and FOG1 was overexpressed in K562 cells. Quantitative ChIP analysis was performed using antibodies against GATA-1, GATA-2, TAL1, FOG1, histone H3 acetylated-K4 (H3K4ac), H3K9ac, H3 trimethylated-K4 (H3K4me3), and H3K27me3. *PU.1* regulatory element was cloned into luciferase plasmid (pGL4.10, Promega) and mutation within the *cis*-element was introduced using a site-directed mutagenesis kit (Agilent). TAL1 loss-of-function analysis was conducted with specific siRNA. For transcription profiling, Human Oligo chip 25K (Toray) was used.
Results: Forced FOG1 expression in K562 cells induced the expression of erythroid genes (*HBA*, *HBB*, and *SLC4A1*), whereas repressed that of *GATA-2*, which have been reported to be FOG1-dependent GATA-1-target genes (Lee *et al*, Mol Cell 2009). On the other hand, FOG1 overexpression did not affect the expression of master regulators of erythropoiesis, such as *GATA-1* and *TAL1*. Next, we conducted microarray analysis to comprehensively characterize FOG1-regulated gene ensemble. The analysis demonstrated that 942 and 180 genes were upregulated and downregulated (> 2-fold), respectively, in the FOG1-overexpressed cells. Noticeably, we found that the expression of *PU.1*, known as a myelo-lymphoid-promoting transcription factor, was strongly downregulated by FOG1 overexpression, indicating that *PU.1* is another FOG1-dependent GATA-1 target. Because GATA-1 ChIP sequencing analysis identified a GATA-1 peak in the *PU.1* promoter (Fujiwara *et al*, Mol Cell 2009), which contained evolutionally conserved consensus GATA-binding motif (AGATAG), we performed a transient luciferase promoter analysis to test whether FOG1-mediated transcriptional repression of *PU.1* could be regulated at the GATA site located at its promoter. Co-transfection of the FOG1 expression vector significantly reduced the promoter activity of *PU.1*, and this effect was clearly diminished by disruption of the GATA motif, suggesting that this motif has an important role in FOG1-mediated transcriptional repression of *PU.1*. Quantitative ChIP analysis demonstrated increased GATA-1 chromatin occupancy at both FOG1-activated (globins, *SLC4A1*) as well as FOG1-repressed (*GATA-2*, *PU.1*) gene loci. However, while TAL1 chromatin occupancy was significantly increased at FOG1-activated gene loci, it was significantly decreased at FOG1-repressed gene loci. When FOG1 was overexpressed in TAL1-knocked down K562 cells, FOG1-mediated activation of *HBA*, *HBG*, and *SLC4A1* was significantly compromised by TAL1 knockdown, suggesting that FOG1 may require TAL1 to activate GATA-1 target genes. To estimate the molecular mechanisms by which FOG1 confers transcriptional repression, we evaluated the epigenetic landscape at FOG1-repressed gene loci. Quantitative ChIP analysis demonstrated that activating marks (H3K4ac, H3K9ac, and H3K4me3) were significantly decreased, whereas repressive H3K27me3 was not affected, by FOG1 overexpression.
Summary/Conclusions: Our results provide important mechanistic insight into the role of FOG1 in the regulation of GATA-1-regulated genes and suggest that FOG1 has an important role in inducing cells to differentiate toward the erythroid lineage rather than the myelo-lymphoid one by repressing the expression of *PU.1*.

E1105

THE STEM CELL ZINC FINGER 1 (SZF1) / ZNF589 PROTEIN INHIBITS TUMOR DEVELOPMENT IN A K562 XENOGRAFT MOUSE MODEL, BLOCKING CELL CYCLING AND INDUCING PREMATURE CELLULAR SENESCENCE

L. Venturini[1,*], C.-W. Lee[1], N. Jyotsana[1], M. Scherr[1], M. Heuser[1], M. Stadler[1], A. Ganser[1]
[1]Hematology, Hemostasis, Oncology, Stem Cell Transplantantion, Hannover Medical School, Hannover, Germany

Background: The stem cell zinc finger 1 (SZF1) / ZNF589 protein, a member of the family of Krüppel associated box domain-zinc finger (KRAB-ZNF) transcription factors, has an isoform exclusively expressed in CD34+ hematopoietic stem/progenitor cells (HSPCs), suggesting its role as epigenetic regulator of specific genes involved in hematopoiesis. The SZF1/ZNF589 gene exhibits a human-specific evolutionary nucleotide DNA-change leading to a complex molecular organization and to a protein structure peculiar for humans, as compared to all other primates, potentially conferring human-specific functional properties. SZF1/ZNF589 has recently been shown to control cell viability in the hematopoietic system. It is regulated by the HIF-1α hypoxia-induced transcription factor and is differentially expressed in a cytokine-dependent manner during hypoxia in CD34+ HSPCs (Venturini et al., Exp Hematol 2016; 44: 257-268). Thus, SZF1/ZNF589 may play a role in the maintenance of hematopoietic stem cell quiescence and survival, known to be influenced by the hypoxic state in the bone marrow niche.
Aims: We studied the effects of SZF1/ZNF589 overexpression *in vitro* and evaluated its tumor suppressor potential *in vivo*.

Methods: K562 (BCR-ABL positive chronic myeloid leukemia in blast crisis)-Luciferase-control or K562-Luciferase-SZF1/ZNF589 cells were directly injected into the femurs of NSG mice and tumor development was monitored by bioluminescence. Furthermore, K562 cells with or without SZF1/ZNF589 overexpression were studied by proliferation assay, cytomorphology, flow cytometry, cell cycle analysis, cyclin B1 expression and beta-galactosidase assay.
Results: K562-dependent tumor growth was efficiently inhibited in NSG mice transplanted with K562-Luc-SZF1/ZNF589-cells as compared to mice transplanted with K562-Luc-control-cells, leading to significantly prolonged survival, demonstrating a strong tumor suppressive potential of SZF1/ZNF589 *in vivo*. In vitro, overexpression of SZF1/ZNF589 dramatically inhibited proliferation of K562 cells which, instead of dying, became giant and dysplastic, without other significant morphological changes and in absence of polyploidy. Cell cycle analysis revealed a blockade in G2/M phase, with cyclin B1 accumulation characteristic for mitotic arrest. As suggested by morphology and beta-galactosidase assay, these cells were entering premature senescence.
Summary/Conclusions: SZF1/ZNF589 controls survival of hematopoietic cells mediated by mitotic arrest and premature senescence, exhibiting tumor suppressing functions *in vivo*.

E1106

THE FUNCTIONAL RELEVANCE OF DNMT3A SPLICE VARIANTS IN HEMATOPOIETIC DIFFERENTIATION

T. Bozic[1], J. Frobel[1], A. Raić[1], S. Heilmann-Heimbach[2], T.W. Goecke[3], E. Jost[4], W. Wagner[1,*]
[1]Stem Cell Biology and Cellular Engineering, Helmholtz-Institute for Biomedical Engineering, RWTH Aachen University Medical School, Aachen, [2]Department of Genomics, Institute of Human Genetics, Life & Brain Center, University of Bonn, Bonn, [3]Department of Obstetrics and Gynecology, RWTH Aachen University Hospital, [4]Clinic for Oncology, Hematology, and Stem Cell Transplantation, RWTH Aachen University Medical School, Aachen, Germany

Background: DNA methyltransferase 3A (DNMT3A) plays a pivotal role for *de novo* DNA methylation (DNAm) during development. It seems to be of particular relevance in hematopoietic differentiation because it is frequently mutated in acute myeloid leukemia or clonal hematopoiesis. So far, it is unclear how DNMT3A governs the multitude of lineage-specific DNAm patterns – it is conceivable that this can at least partly be attributed to alternative splicing of *DNMT3A*.
Aims: In this study, we followed the hypothesis that specific splice variants of *DNMT3A* impact on hematopoietic differentiation or DNAm patterns. Therefore we addressed the role of specific splice variants of *DNMT3A* in hematopoietic stem and progenitor cells (HSPCs).
Methods: Expression of *DNMT3A* splice variants was modulated in HSPCs: transcript 1+3 (Tr.1+3), transcript 2 (Tr.2), or transcript 4 (Tr.4) of *DNMT3A* were either knocked down by short hairpin RNA or constitutively overexpressed by lentiviral infection. Expression changes were validated by qRT-PCR. Subsequently, we evaluated the impact on colony formation potential (CFU assay), proliferation (CFSE assay), and the immunophenotype (CD34+ and CD133+). Global DNAm profiles were generated with the Infinium HumanMethylation450 BeadChip platform and gene expression profiles with the Human Affymetrix Gene ST1.0 platform.
Results: Downregulation of either Tr.2 or Tr.4 reduced the proliferation rate of HSPCs significantly (n=3, p<0.05). HSPCs maintained CD34 expression for a higher number of cell divisions upon knockdown of Tr.2 (n=3; p<0.05). In colony forming unit (CFU) assays downregulation of Tr.4 resulted in a clear bias towards erythroid colonies (n=3, p<0.05). Overall, CFU frequency was reduced by knockdown of *DNMT3A* transcripts, whereas it was increased by overexpression. Subsequently, we analyzed the impact of specific *DNMT3A* variants on the DNAm patterns: several CpG sites revealed significant differences in DNAm levels upon knockdown of Tr.2 and Tr.1+3 (8,905 and 352 CpGs, respectively; n=3, adjusted p-value <0.05). Notably, these patterns were regulated in the opposite direction upon overexpression of the same transcripts. Knockdown of Tr.4, which does not have the DNA-methyltransferase domain, did not evoke significant changes in DNAm. Furthermore, modulation of *DNMT3A* splice variants resulted in transcript-specific gene expression changes, which may at least partly be attributed to the DNAm changes.
Summary/Conclusions: Our results demonstrate that the various splice variants of *DNMT3A* have different functional sequel on HSPCs. Knockdown and overexpression resulted in opposite and transcript-specific DNAm changes. Thus, alternative splicing of *DNMT3A* is relevant for site-specific epigenetic modifications in hematopoietic development.

ERYTHROPOIETIN STIMULATES TRANSDIFFERENTIATION OF BONE MARROW PRO-B CELLS INTO BONE-RESORBING OSTEOCLASTS

N. Deshet-Unger[1], S. Hiram-Bab[2], N. Ben-Califa[1], A. Kolomansky[1,3], D. Gilboa[1], T. Liron[2], H. S. Oster[3,4], M. Mittelman[3,4], Y. Gabet[2], D. Neumann[1,*]
[1]Cell and Developmental Biology, [2]Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University, [3]Medicine A, Tel Aviv Sourasky Medical Center, [4]Tel Aviv University, Tel-Aviv, Israel

Background: Erythropoietin (EPO) is a crucial kidney-derived hormone responsible for erythropoiesis; however, its extra-erythroid effects are substantial and correlate with EPO receptor (EPO-R) expression in both hematopoietic and non-hematopoietic tissues. Bone turnover is regulated by the coupled actions of osteoblasts, the bone-forming cells, and monocyte-derived osteoclasts, which mediate bone resorption. In this regard, we have recently reported that EPO directly stimulates bone resorption *via* activation of EPO-R signaling in the monocytic lineage (Hiram-Bab et al., 2015). Monocyte differentiation into osteoclasts relies on monocyte-macrophage colony-stimulating factor (M-CSF) and the receptor activator of nuclear factor kappa B ligand (RANKL). B cells are also known to regulate bone metabolism, chiefly *via* paracrine signals. Osteoclasts and B cells arise from distinct myeloid and lymphoid progenitors, respectively, which are downstream of a common multipotent progenitor cell.
In the bone marrow (BM), Pro-B cells sequentially differentiate into Pre-B and immature B cells. Whether BM B cells can transdifferentiate into osteoclasts remains controversial, since osteoclast differentiation from residual monocytic precursors in the cultures was not excluded in earlier studies.
Aims: We set to determine whether B cells can transdifferentiate to osteoclasts and to assess the effect of EPO on this process.
Methods: Experiments were conducted on C57BL/6J or CD19-Cre;R26R-EYFP, 8-12-week-old female mice in accordance and with the approval of the Institutional Animal Care and Use Committee of Tel-Aviv University (M-14-043). BM cells were flushed from femurs, tibias, and pelvic bone and red blood cells were lysed. Cells were stained with labelled anti-mouse antibodies: PE-B220, FITC-CD19, PerCP-IgM, PeCy7-CD43, and APC-M-CSF receptor/CD115; and sorted by flow cytometry. Cells were then cultured in α-MEM containing 10% fetal bovine serum, M-CSF and RANKL. Multinucleated osteoclasts were stained for tartrate-resistant acid phosphatase (TRAP) and pit resorption was assessed.

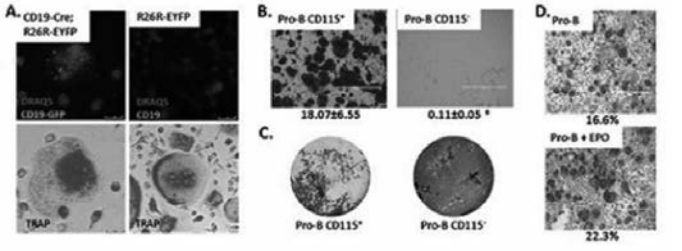

Figure 1.

Results: B cells isolated from BM of CD19-Cre:R26R-EYFP mice cultured with M-CSF and RANKL differentiated into TRAP$^+$ multinucleated osteoclasts that were also positive for EYFP, thus tracing back their B cell origin (Figure 1A). Next, we dissected which B cell precursor subtype possesses this osteoclastogenic capacity and found that only Pro-B (B220$^+$CD19$^+$CD43^{High}IGM$^-$), but not Pre-B (B220$^+$CD19$^+$CD43^{Low}IGM$^-$) nor immature B cells (B220$^+$CD19$^+$CD43$^-$IGM$^+$) could transdifferentiate into osteoclasts (16%±3.7 *vs.* 0.79%±0.28 and 0.48%±0.13 osteoclasts' area, respectively). Moreover, among the Pro-B cells, only those expressing M-CSF receptor (CD115) could transdifferentiate into functional osteoclasts (18%±6.55 *vs.* 0.11%±0.05 osteoclasts' area, respectively, Figure 1B and C). Using an anti-EPO-R specific antibody we detected EPO-R on the surface of B cells and noted that EPO enhanced the differentiation of the Pro B cells into osteoclasts by as much as 70% (p=0.04) (Figure 1D). **Figure 1: Osteoclastogenesis** *in vitro* **from sorted B cells. (A)** Transdifferentiation of 180,000 cells/well CD19-Cre;R26R-EYFP into osteoclasts. DRAQ5 (blue) and anti-GFP (green) for CD19-Cre;R26R-EYFP and CD19-Cre cells. Bottom - TRAP staining. Confocal images (x20 magnification) **(B)** TRAP staining of osteoclasts derived from the indicated sorted cells from BM (10,000 cells/well) and cultured with M-CSF and RANKL. Left – Pro-B cells expressing CD115 (B220$^+$CD19$^+$CD43^{High}IgM$^-$CD115$^+$). Right – Pro-B cells not expressing CD115 (B220$^+$CD19$^+$CD43^{High}IgM$^-$CD115$^-$). Data are mean±SEM of osteoclast area, n=5 mice in each group; *p<0.05. **(C)** Pit resorption area from the indicated sorted cells cultured on calcium phosphate-coated plates. **(D)** TRAP staining of osteoclasts derived from sorted Pro-B cells (B220$^+$CD19$^+$CD43^{High}IgM$^-$ cells; 180,000cells/well)±5U/ml EPO, n=7 mice in each group. Data are% osteoclasts of a representative image; EPO *versus* Control was 70% increase, p<0.05.
Summary/Conclusions: Taken together, our data suggest a new physio-pathological role for BM B-cell precursors in bone metabolism via their capacity to differentiate into functional osteoclasts, and a possible role for EPO in this process.

[1]Haematopoietic Stem Cell Biology Laboratory, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [2]Clinical Hematology Department, Coimbra Hospital and Universitary Centre, Coimbra, Portugal, [3]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [4]Department of Cell and Molecular Biology, [5]Department of Medicine, Huddinge, Center for Hematology and Regenerative Medicine, Karolinska Institute, Stockholm, Sweden, [6]Computational Biology Research Group, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Notch signaling is a highly conserved pathway important in multiple developmental processes. Canonical signaling through all Notch receptors converges on the Csl transcription factor recombination signal binding protein for immunoglobulin kappa J region (Rbpj). In haematopoiesis, Notch is critical for the emergence of definitive hematopoietic stem cells (HSCs) in the embryo and in thymic T cell development. Contrastingly, canonical Notch signaling has been shown to be dispensable for HSC homeostasis in the adult bone marrow (aBM). Recent studies have however suggested a role of Notch in promoting megakaryocyte (Mk) and erythroid (E) progenitor cell development as well as in suppressing granulocyte-macrophage (GM) progenitor expansion and acting as a tumor-suppressor in myeloid malignancies. However, these findings were largely made through genetic approaches potentially also affecting regulatory pathways distinct from canonical Notch signaling.
Aims: To unambiguously investigate the role of canonical Notch signaling in aBM myelopoiesis, in steady-state and following transplantation.
Methods: B6-SJLCD45.1, *Rbpj$^{fl/fl}$, Mx1-Cre*, *Vav-Cre* and *Vwf-eGFP* BAC mice were used. Flow cytometry (FACS) was applied for phenotypic analyses. Gene expression levels were measured by real-time reverse transcription-PCR. Mk/E and GM *in vitro* colony forming potentials were applied in mouse colony assays. For transplantation study, lethally irradiated recipients were competitively transplanted (1:1) and reconstitution assessed 7-9 weeks after transplantation.
Results: FACS staging of GM, Mk and E progenitors in aBM of *loxP*-flanked *Rbpj* mice crossed to both *Mx1-Cre* and the pan-hematopoietic *Vav-Cre* strains was applied. As expected, HSCs were unaffected. Not previously investigated, FACS analysis of distinct stages of GM, Mk and E progenitors revealed no defects, at any progenitor stage, in *Rbpj*-deficient mice. To demonstrate that this lack of a phenotype was not due to BM cells escaping *Rbpj* deletion, we FACS purified HSCs and all GM, Mk and E progenitor stages from *Rbpj*-deficient mice and verified a virtually complete deletion of *Rbpj* in all populations. In further agreement with canonical Notch signaling not being required for steady-state generation, maintenance or stepwise differentiation of adult GM, Mk and E progenitors, the number of GM, E and Mk colonies generated from unfractionated aBM cells as well as circulating platelet counts were also unaffected in *Rbpj*-deficient mice. We next sought to address whether we could uncover a role of the Notch pathway in regulation of GM, Mk and E progenitors by establishing BM chimeras in which *Rbpj*-deficient progenitors compete with wild type (WT) progenitors for replenishment and differentiation in lethally irradiated recipients. No deficiencies were observed in the replenishment of HSCs and any stages of GM, Mk and E progenitors in mice competitively transplanted with *Rbpj*-deficient as compared to control WT BM cells. Moreover, transplanted *Rbpj*-deficient and control progenitors contributed equally well to platelet reconstitution. We next investigated whether loss of canonical Notch signaling might nevertheless impact on expression of genes for key regulators the Mk and E lineages at distinct progenitor stages for these lineages, as previously implicated. Notably, transcript levels of genes encoding key Mk/E regulators were unaffected in *Rbpj*-deficient Mk/E progenitors. In previous studies, expression of Notch target genes in Mk and E progenitors in aBM has been implicated as reflecting activation through Notch signaling. However, since the expression of Notch targets might also be regulated by other pathways besides Notch pathway, we investigated whether the expression of key Notch target genes (*Hes1, Hes5, Nrarp* and *Gata3*) in Mk/E progenitors in aBM was dependent on canonical Notch signaling. Neither in HSCs or any Mk/E progenitor was the expression of these Notch genes negatively affected by *Rbpj*-deficiency, demonstrating that their low expression levels in aBM HSCs and Mk/E is independent of canonical Notch signaling.
Summary/Conclusions: Studies implicating canonical Notch signaling as a critical regulator of aBM Mk, E and GM progenitors potentially failed to target only canonical Notch signaling. Herein, we demonstrate that canonical Notch signaling is dispensable for generation and replenishment of Mk, E and GM progenitors in aBM in steady-state as well as following BM transplantation.

E1111

IDENTIFICATION OF NOVEL HUMAN HEMATOPOIETIC STEM CELL SUBPOPULATIONS VIA COMPREHENSIVE SURFACE MARKER ANALYSIS

T. Jiromaru[1,*], K. Miyawaki[1], Y. Mori[1], H. Iwasaki[1], T. Maeda[1], K. Akashi[1]
[1]Medicine and Biosystemic Science, Kyushu University, Fukuoka, Japan

Background: All hematopoietic cells are derived from hematopoietic stem cells (HSCs), which exhibit capacities for multilineage differentiation and long-term self-renewal. Human HSCs can be isolated by Fluorescence-activated cell sorting (FACS) with the combination of several surface markers, such as CD34, CD38, CD45RA and CD90. The HSC fraction reportedly consists of functionally heterogeneous subpopulations, including multi-potent and/or lineage-biased progenitors {Notta:2016hj} and HSC-like populations with reduced self-renewal capacity {Notta:2011bg}; however, prospective isolation of bona fide human HSCs is still challenging due, at least in part, to the lack of specific markers.
Aims: The goal of this study is to identify a novel HSC-specific surface marker(s) that enables prospective isolation of functionally-distinct HSC subpopulations.
Methods: We examined expression levels of 342 cell surface markers in the HSC fraction (Lin-CD34+CD38-CD45RA-CD90+) by FACS using commercially-available antibodies. Single-cell gene expression profilings of isolated subfractions were performed using Fluidigm C1 system in combination with Biomark. Differentiation potential of each HSC fraction was assessed by single-cell colony assays in methylcellulose. *in vitro* lineage tracing in liquid culture were performed to determine hierarchical relationships among subfractions.
Results: Among 342 cell surface proteins examined, only CD35, CD115 and CD215 were detected in the HSC fraction. We focused on CD35, which is also known as complement receptor type 1 (CR1), as its expression was most distinct among the three markers. CD35-positive population accounted for 15~50% of the human HSCs, defined as Lin-CD34+CD38-CD45RA-CD90+ cells, in adult bone marrow and cord blood. HSCs exhibited multi-lineage reconstitution capacity without lineage-biased differentiation in a single-cell colony assay regardless of the CD35 levels. CD35+HSCs gave rise to CD35-HSCs in lineage tracing experiments, suggesting that CD35+HSCs reside upstream of CD35-HSCs in the hierarchy of hematopoietic differentiation. Single-cell gene expression profiling of CD35-positive or -negative HSCs indicated that CD35+HSCs, but not CD35-HSCs, are phenotypically homogenous, expressing cell cycle-related genes and lineage-specific markers at low levels.
Summary/Conclusions: Our data suggest that HSCs can be further subdivided into subfractions based on CD35 levels. CD35 might be a useful marker to prospectively isolate the most primitive human HSC fraction. *in vivo* functional assays using xenotransplantaion models are currently underway, and the results will be discussed at the meeting.

E1112

DEVELOPMENT OF A 3-DIMENSIONAL CULTURE TO MIMICK THE BONE MARROW MICROENVIRONMENT AND RECAPITULATE DRUG RESISTANCE FOR IN VITRO STUDY

M. Karimpoor[1,*], E. Illangakoon[1], A. Reid[2], J. Khorashad[2], M. Edirisinghe[1]
[1]Biomechanical engineering/Pharmacy, University College London, [2]Department of Medicine, Imperial College London, London, United Kingdom

Background: Chronic myeloid leukemia (CML) is a haematological malignancy caused by acquisition of the *BCR-ABL1* oncogene. Demonstration of the central role of BCR-ABL1 kinase activity in CML pathogenesis led to the development of imatinib, an ABL1-specific tyrosine kinase inhibitor. Most patients on imatinib attain good clinical and molecular responses, despite the persistent presence of a low level of therapy-refractory leukaemia stem cells (LSCs), which reside in the bone marrow niche. However, in a significant minority of patients these cells eventually provide a reservoir for disease relapse and subsequent malignant progression. A greater understanding of the biology of imatinib-resistant LSCs could therefore be of significant clinical benefit. One of the proposed mechanisms of drug resistance in CML LSCs is close contact with the surrounding microenvironment, however an in-vitro model of the bone marrow matrix is currently lacking.
Aims: Development of a 3-Dimnsional culture using fibre scaffolds to mimick bone marrow microenvironment in order to study the mechanism of resistance to anti-leukaemia agents
Methods: Scaffold production: PMMA solution was prepared by dissolving PMMA in chloroform and adding appropriate amount of hydroxyapatite to polymer solution followed by pressurized gyration and collection of the PMMA fibres using a rod - collector. **2 Dimensional (2D) Cell culture:** K562 and HL60 cell lines were cultured and treated with or without imatinib or doxorubicin respectively.**3D Cell culture:** The same experiment was performed in the presence of scaffolds. **Co-culture of HS-5 with HL60 or K562 cells:** GFP$^+$ stromal cells HS-5 cells were added to PMMA-HA scaffold. K562 and HL60 cells were treated in the presence or absence of imatinib and doxorubicin in HS-5 cells plus scaffold environment respectively and were investigated for proliferation and viability 72h later.
Results: We produced a PMMA-based 3D scaffold and compared the growth of CML and AML cell lines grown in this scaffold in the presence and absence of cytotoxic or targeted therapy to that of cells grown in 2D culture. PMMA-HA scaffold was not toxic to the leukaemia cells as primary AML cells and also K562 cells grew in the presence of scaffold and also concentrated around the

fibres. Treatment of K562 or HL60 cells with imatinib or doxorubicin respectively resulted in a lower level of apoptosis in cells grown on the 3D scaffold compared to those grown in 2D culture. Further development of this 3D culture by adding stromal cells HS-5 to the scaffold reduced even further the sensitivity of K562 or HL60 to imatinib or doxorubicin, respectively.

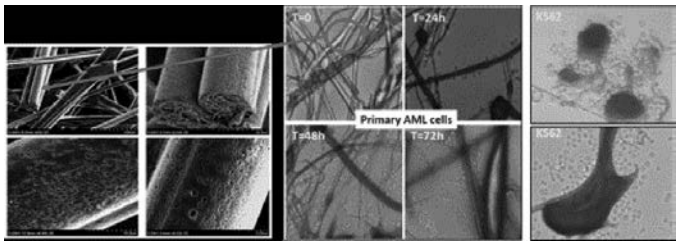

Figure 1.

Summary/Conclusions: The relative resistance to either imatinib or doxorubicin that we observed in cells grown in 3D culture supports a role for the bone marrow matrix in the protection of leukaemic cells against chemotherapeutic agents. A combination of the PMMA-HA with HS-5 cells made this system more similar to the bone marrow microenvironment as this is a model in which all the basic components of the bone marrow microenvironment such as scaffold, stromal cells and cytokines (secreted by HS-5) are present. The results of this study show adding extra complexity to the microenvironment changes the sensitivity of the cells to therapeutic agents, better recapitulating the situation observed in-vitro. Three dimensional cultures using the PMMA-HA/HS-5 model may prove useful in the investigation of therapy resistance in leukaemia and for the discovery of new agents capable of eradicating quiescent leukaemic stem cells.

WHOLE EXOME SEQUENCING REVEALED SEQUENTIAL GAIN OF MUTATIONS IN TWO CASES OF DONOR CELL HAEMATOLOGICAL MALIGNANCY AFTER HEMATOPOIETIC TRANSPLANTATION

J. Suárez González[1,2,*], C. Martínez-Laperche[2,3], M. Kwon[2,3], G. Rodríguez-Macías[3], A. Figuera[4], A. Balas[5], N. Martínez[6], P. Balsalobre[2,3], D. Serrano[2,3], M.Á. Piris[6,7], J.L. Vicario[5], J. Gayoso[2,3], J.L. Díez[23], I. Buño[1,2,3]
[1]Genomic Unit, Instituto de Investigación Sanitaria Gregorio Marañón y Hospital General Universitario Gregorio Marañón, [2]Instituto de Investigación Sanitaria Gregorio Marañón, [3]Department of Hematology, Hospital General Universitario Gregorio Marañón, [4]Department of Hematology, Hospital de la Princesa, [5]Departament of Histocompatibility, Madrid Blood Centre, Madrid, [6]Cancer Genomics, IDIVAL, [7]Department of Pathology, Hospital Marqués de Valdecilla, Santander, Spain

Background: The leukemic transformation of otherwise healthy donor stem cells provides a useful *in vivo* model to study the mechanisms involved in leukemogenesis.
Aims: We report two cases of donor cell derived haematological malignancy in which whole-exome sequencing (WES) was performed in bone marrow (BM) samples from recipient at different times after allogeneic hematopoietic stem cell transplantation (allo-HSCT) in order to study the dynamics of emergence of mutations that precede the development of donor cell leukemia (DCL) and donor cell myelodysplastic syndrome (DC-MDS).

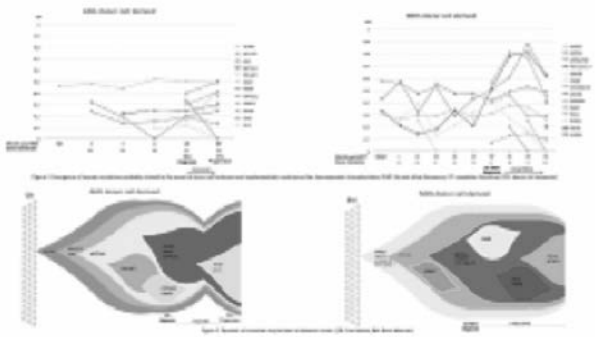

Figure 1.

Methods: Case 1: A 43-year-old female diagnosed with lymphoblastic leukemia-B t(1;19), who developed acute myeloid leukemia (AML) with normal karyotype, *NPM1*+of donor origin 16 months after unrelated cord blood transplantation (UCBT). Case 2: A 65-year-old male diagnosed with mantle cell lymphoma, who developed MDS 45,XX,-7,del(12)(p12) of donor origin, 57 months after allogeneic BM transplantation from his HLA-identical brother. WES (SureSelect-XT Human-exon 50Mb) was performed by next generation sequencing (Hiseq) on donor stem cells (SCs) infused as well as on BM samples from recipient after allo-HSCT. The exome of donor SCs and 5 BM samples, from case 1, were aligned to the human reference genome (GRCh 37/hg19) and donor SCs and 9 BM samples were aligned to GRCh 38/hg38 in the second case.
Results: WES analysis revealed progressive emergence of multiple somatic mutations probably related to the development of leukemia in bone marrow samples post allo-HSCT (Figure 1). Both SCs showed alterations that may be involved in leukemogenesis. (Case 1: *SH2B3* and case 2: *KMT2C, KMT2A, ARHGAP26* and monosomy 7). Somatic mutations, acquired over time, fall into genes that play well-established roles in signalling pathways. Mutations in leukemic subclones that disappear after chemotherapy were indentified, as well as the acquisition of new mutations in resistant subclones. We propose a possible model of leukemogenesis in these cases (Figure 2).
Summary/Conclusions: The present study reveals a process of sequential clonal expansions, promoted by the acquisition of additional somatic mutations in donor hematopoietic cells. Detection of heritable or acquired gene mutations in donor associated with predisposition to haematological malignancies could have clinical implications for the patients undergoing to allo-HSCT. Although the cause of donor cell derived haematological malignancy onset seems to be multifactorial, the infusion of a SCU with pre-leukemic potential in a context of residual toxicity in recipient as a result of pre-transplant chemotherapy, a post-transplant environment characterized by a decreased immune surveillance may well have played role in these cases. The study of a greater number of DCL cases by next generation sequencing could help to understand this process and to detect new mutations involved in the emergence of AML.

E1114

LEUKEMIC STEM CELL-RELATED MRNA EXPRESSION ANALYSIS USING A NOVEL FLOW CYTOMETRY-BASED ASSAY

B. Depreter[1,2,*], K. Vandepoele[3], B. De Moerloose[4], B. Denys[3], J. Philippé[1,3], T. Lammens[2]
[1]Department of Clinical Chemistry, Microbiology and Immunology, [2]Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent University, [3]Department of Laboratory Medicine, [4]Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent University Hospital, Ghent, Belgium

Background: Gene expression analysis of protein-coding (mRNA) and non-coding RNA in paediatric and adult acute myeloid leukaemia (AML) has become of paramount importance for therapeutic decision-making, revealing prognostic information and for the identification of novel therapeutic targets. AML is a clinically, phenotypically and molecularly heterogeneous haematological malignancy, with different leukemic cell populations organized in a hierarchical fashion, and leukemic stem cells (LSCs) residing at the apex herein. Unfortunately, gene expression profiling is commonly performed on unfractionated bulk samples, leading to 'expression averaging' of these heterogeneous leukemic cell populations. Multicolor flow cytometry (FCM) is capable of distinguishing heterogeneous cell populations based on the phenotypic characterization at a single-cell level. However, fluorochrome-conjugated antibodies are not available for intracellular RNA targets.
Aims: To evaluate the applicability of a novel flow cytometry-based technique, PrimeFlow™ RNA assay, to measure cell-of-interest RNA expressions in heterogeneous AML samples.
Methods: Technical assessment was performed using six neuroblastoma cell lines with varying levels of *MYCN* gene amplification. Correlation to expression data obtained by the gold standard RT-qPCR, performance in rare (0.1%) cell populations, effects of cryopreservation and off-target effects were evaluated. Next, diagnostic material of *de novo* AML patients was used to measure target gene (*Wilms' tumor 1* (*WT1*)) and reference gene (*RPL13a, GAPD*) expression. Expression analysis was performed in unfractionated bulk leukemic cells as well as blasts and rare subsets of leukemic cells, *e.g.* LSCs. FCM analyses were performed on a FACSCanto II (BD Biosciences) with set-up according to EuroFlow guidelines. Infinicyt™ (Cytognos®) was used for data analysis and mean fluorescence intensities (MFI) values (with/without normalisation) were interpreted. P-values < 0.05 were considered significant.
Results: mRNA expression quantified by PrimeFlow™ significantly correlated with data obtained by RT-qPCR and remained detectable in rare (0.1%) cell populations. *WT1* expression was shown to be statistically significantly higher in bulk leukemic cells of those patients characterized by *WT1* overexpression, as defined by RT-qPCR, showing a mean 52% MFI upregulation by PrimeFlow™ if WT1 overexpression was present, as shown by the gold standard RT-qPCR. Moreover, *WT1* overexpression could be detected within heterogeneous cell populations, *e.g.* the CD34+CD38+ cell population and the LSC (defined as CD34+CD38-), showing a 63% and 45% MFI upregulation, respectively, compared to patients with normal *WT1* expression levels, although only statistically significant in the former population. *GAPD* and *RPL13a* expression differed intra- and interpatient in the bulk (defined as CD34+) and both of the aforementioned populations. Interestingly, reference gene expression was consistently higher in CD34+/CD38+ cells compared to LSCs.

Summary/Conclusions: Key mRNA target expressions in AML, *e.g. WT1* gene expression, could be evaluated using PrimeFlow™ RNA assay, including rare and heterogeneous cell populations herein, *e.g.* LSCs. This study demonstrates that PrimeFlow™ is a technique of interest for the discovery of novel LSC-specific targets.

E1115

POTENTIAL PREDISPOSING GERMLINE MUTATIONS IN PATIENTS WITH CONCOMITANT MYELOID AND LYMPHOID MALIGNANCIES

F. Asmar[1,*], M. Munk Johansen[1], T.C. El-Galaly[2], H.E. Johnsen[2], C. Westmose Yde[3], D. El Fassi[4], K. Grønbæk[1]
[1]Department of Hematology, Rigshospitalet, Copenhagen, [2]Department of Hematology, University hospital of Aalborg, Aalborg, [3]Center of Genomic Medicine, Rigshospitalet, Copenhagen, [4]Department of Hematology, University Hospital Herlev and Gentofte, Herlev, Denmark

Background: Recent findings have suggested that mutations predisposing the development of either acute myeloid leukemia (AML) or chronic lymphocytic leukemia (CLL) may arise in pre-leukemic hematological stem cells. In addition, genes involved in epigenetic regulation, such as *TET2*, and RNA processing, such as *SFB31*, are mutated in both myeloid and lymphoid malignancies. This could indicate a possible genetic link between myeloid and lymphoid malignancies. Therapy related AML (t-AML) is a known complication to treatment with cytotoxic drugs such as alkylating agents and topoisomerase inhibitors. The susceptibility of developing t-AML has been associated with variation in DNA-repair pathways, drug metabolism and transport.
Aims: In this study, we aimed to investigate a possible common genetic origin of hematological cancers in patients with concomitant CLL and *de novo* AML or myelodysplastic syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.
Methods: The presence of concomitant lymphoid and myeloid malignancies in patients is rare, however we managed to include 3 patients with *de novo* AML and CLL, one patient with MDS and CLL, one patient with chronic myelomonocytic leukemia(CMML) and CLL, and two patients with t-AML and CLL. The patients' diagnoses were based on the evaluation of the morhophology, immunohistochemsitry, cytogenetics, and flowcytometry analysis in accordance to the WHO classification. For each patient mononuclear cells (MNCs) from blood or bone marrow were isolated using Ficoll gradient centrifugation and used for fluorescence activated cell sorting (FACS) of the malignant clones and the T-cells. Paired end exome sequencing (2x150) aiming for an average coverage of 50-100x was performed using either the HiSeq2500 or NextSeq500 platforms from Illumina. Raw sequencing data was processed using CASAVA-1.8.2. Mapping to the human genome (hg19/GRCh37 UCSC) was performed using CLC Biomedical Genomics Workbench (Qiagen) mapping cell software. Variants with a frequency of 5% or above were called.
Results: We identified possible pre-disposing germline mutations in all 7 patients by comparing variants between the myeloid malignant clone, CLL cells, and T cells, as well as using saliva to aid in characterizing the mutations as either germline or only present in the hematological compartment. In all the patients except one with *de novo* AML and CLL, we identified a potential damaging germline variant in a DNA-repair related gene, such as *ATM (*387dupA, D130fs*4), *SMARCAL1 (*2114C>T, T705I), *HELQ (*393_397delAGGTG, G132fs*16), *SWI5* (652C>T, R218*), *LIG1*(2168A>G, Q761R) and *PRKDC*(902G>A, C301Y). In the remaining patient with concomitant *de novo* AML and CLL, we identified a potential damaging germline variant in an epigenetic regulator believed to play a role in normal and malignant hematopoiesis, *KDM2B(*44delC, P15fs*92). Furthermore, we identified the somatic mutational landscapes of the malignant clones using T-cells as germline tissue for the patients with concomitant *de novo* AML/MDS/CMML and CLL and for the two patients with t-AML and CLL. The somatic mutational landscapes of the malignant clones in the *de novo* concomitant cases and the cases with CLL and t-AML were quite similar to what has previously been reported in isolated cases of disease. The myeloid and lymphoid malignant clones did not share any of the mutations, indicating development of two independent malignancies.
Summary/Conclusions: Our results suggest a possible role of germline variations in the susceptibility to development of concomitant *de novo* hematological cancers as well as t-AML. However, further studies including more patients are needed to confirm this hypothesis.

E1116

THE MUTATIONAL LANDSCAPE OF DNMT3A MUTATIONS IN CLONAL HAEMATOPOIESIS OF INDETERMINATE POTENTIAL. CHIPPING AWAY AT THE PROBLEM

S. Chaudry[1,*], T. Chevassut[1]
[1]Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Dysfunction of epigenetic modifiers contributes significantly to the pathogenesis of acute myeloid leukaemia (AML). One frequently mutated gene involved in epigenetic modification is DNMT3A (DNA methyltransferase-3-alpha). Approximately 22% of de-novo AML and 36% of cytogenetically normal AML are found to have DNMT3A mutations and around 60% of these mutations affect the R882 codon. In particular, the R882H mutation has been associated with a poor prognosis and survival outcomes for patients. A large number of DNMT3A mutations are present in clonal cells in healthy individuals with no characteristics of haematological malignancy and is termed as clonal haematopoiesis of indeterminate potential (CHIP).

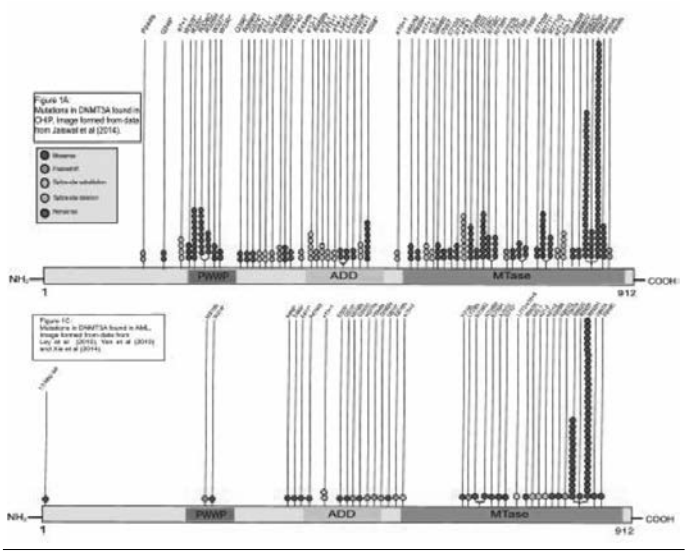

Figure 1.

Aims: We aimed to compare here the locations and types of mutations identified in AML and in CHIP in the DNMT3A gene by several different studies.
Methods: To review the mutations found in CHIP and AML, we carried out an extensive literature search of CHIP studies and AML studies that had mapped a large number of mutations in this gene. Mutations were collated to form several diagrams illustrating and comparing these findings.
Results: When DNMT3A mutations in CHIP were compared to mutations in AML the R882 residue was still found to be the most frequently mutated residue in both CHIP and AML. Figure 1 clearly illustrates the mutations in comparison to AML. However, only 13% of all reported mutations were found at the R882 residue in CHIP, while in AML 60% DNMT3A mutations are found at the R882H mutations.
Summary/Conclusions: Analysis of the mutational landscape of CHIP has clearly highlighted the role of DNMT3A mutations in clonal haematopoiesis in older healthy individuals, the significance of such preleukaemic clones is yet to be determined.

NEXT-GENERATION REFERENCE INTERVALS FOR PEDIATRIC HEMATOLOGY

J. Zierk[1,*], J. Hirschmann[2], D. Toddenroth[2], F. Arzideh[3], T. Streichert[4], R. Haeckel[5], H.-U. Prokosch[2], M. Rauh[1], M. Metzler[1]
[1]Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, [2]Chair of Medical Informatics, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, [3]Department of Statistics, University of Bremen, Bremen, [4]Department of Clinical Chemistry, University Hospital of Cologne, Cologne, [5]Bremer Zentrum für Laboratoriumsmedizin, Klinikum Bremen Mitte, Bremen, Germany

Background: Interpretation of hematology analytes in children is challenging due to extensive changes in hematopoiesis with age leading to pronounced sex- and age-specific dynamics. To facilitate clinical decision making based on quantitative hematology test results, reference intervals are used to classify samples according to upper and lower limits, and age-related change is represented using reference intervals partitioned into separate age groups. However, this approach can only approximate the continuous physiological dynamics of hematological analytes in childhood and does not enable appropriate quantification of test results in relation to the reference distribution. Conversely, percentile charts as used in anthropometric quantities (e.g. pediatric weight-for-age charts) would allow adequate appreciation of pediatric hematology test results. However, the ethical and practical challenges unique to pediatric reference intervals have restricted the creation of such percentile charts, and limitations in current approaches to laboratory test result display prevent their integration into clinical decision making.
Aims: To create percentile charts for hematology analytes from birth to adulthood using a data-mining approach and to demonstrate their integration into clinical care with benefits in clinical decision making.

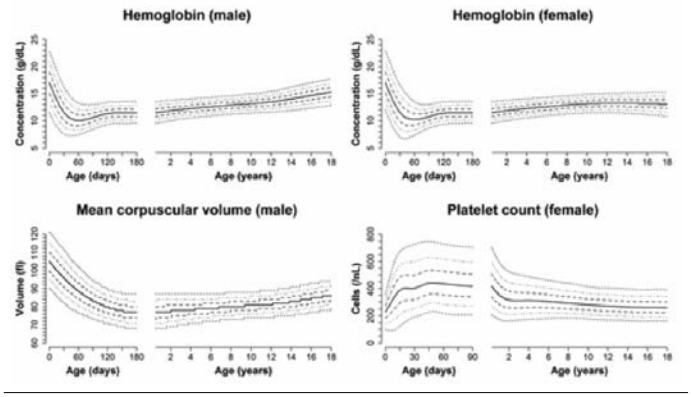

Figure 1.

Methods: We applied a data-mining algorithm to generate percentile charts for hematology analytes using laboratory data collected during the clinical care of patients. A total of 9,517,245 samples from 343,463 patients (72,614–337,011 samples per analyte) from 8 German tertiary care centers and 2 German laboratory service providers were examined. Percentile charts were calculated using an established statistical approach which extracts the proportion of samples from healthy individuals from the unfiltered input dataset containing both non-pathologic and pathologic samples. To evaluate the clinical benefit of hematology test result interpretation using percentile charts, accuracy and speed of pediatricians assessing eight different predefined clinical situations were measured in comparison to conventional test result representations.
Results: We created percentile charts for hematology analytes in girls and boys from birth to 18 years which can be used as common reference intervals. Results are provided for hemoglobin, hematocrit, red cell indices, red cell count, red cell distribution width, white cell count, and platelet count, example charts for hemoglobin, mean corpuscular volume, and platelet count are shown in the accompanying figure. A web application at www.pedref.org/hematology demonstrates hematology test result interpretation using percentile charts and z-scores with special consideration of pediatric dynamics. Comparison of pediatricians' decision times when assessing different clinical scenarios using percentile charts and conventional representations shows more correct decisions (75.9% *vs* 68.4%, p<0.01) which are made in shorter time (2.7 s *vs* 3.8 s, p<0.01) when using percentile charts.
Summary/Conclusions: The created percentile charts enable the appropriate differential diagnosis of changes in hematology analytes due to disease and changes due to physiological development. Integration of suitable forms of result reporting using the provided percentile charts into clinical decision making improves assessment of the unique dynamics in pediatric hematology.

E1118

GROWTH FACTOR INDEPENDENCE 1 (GFI1) REGULATES THE AML SUPPORTING FUNCTION OF MESENCHYMAL STROMAL CELLS

Y. Al-Matary[1,*], L. Botezatu [1], A. Thivakaran [1], R. Köster[1], J. Schütte [1], J. Göthert [1], U. Dührsen[1], B. Opalka[1], C. Khandanpour[1]
[1]University Hospital of Essen/ West centre of tumor, Essen, Germany

Background: Mesenchymal stromal cells (MSCs) harbor and support the function of normal hematopoietic stem cells. Less is known about their interaction with leukemic cells, *e.g.* in acute myeloid leukemia (AML). The prognosis of AML, a clonal malignant disease of the bone marrow (BM), is still poor with only 25% of patients living longer than 5 years.
Aims: In the current study, we investigated the interaction between MSCs and AML cells. and we also investigated the underlying molecular mechanism.
Methods: We used cell cultures using primary cells from human and mice and cell lines of MSCs and AML cells. Different Mouse models of human AML were used in our study to confirm the results obtained from human sample. MSCs were characterized by differentiation assay, flow cytometry and RT-PCR. Matrigel test was also applied in this study.
Results: MSCs from AML patients called AML-associated MSCs (AMSCs) or from murine models of human leukemia enhance significantly *in vitro* the growth of leukemic cells compared to AML cells growing without MSCs or in presence of MSCs from non-leukemic patients or mice. Among other, AMSCs increased entry of leukemic cells into the cell cycle, and at the same time protected the leukemia cells against exogenous toxic events such as chemotherapy or irradiation. The interaction between AMSCs and leukemia cells is dependent on cell-to-cell contact. *In vivo*, absolute and relative numbers of AMSCs and other stromal cells, *i.e.* endothelial cells and osteoblast lineage cells were highly expanded in the BM of mice modeling of human AML. AMSCs showed a higher efficiency of capillary tube formation in the matrigel assay than normal MSCs which gives an additional indication that AMSCs were polarized by leukemia cells towards a tumor-supporting state. On a molecular level, the polarization of MSCs towards an AML-supporting state depends on upregulated expression of the transcription factor Growth factor independence 1 (Gfi1). Loss of Gfi1 diminished the tumor-supporting state of AML-associated MSCs.
Summary/Conclusions: We conclude that leukemia cells polarize AMSCs towards a leukemia-supporting state in a Gfi1-dependent manner, which could open the way to new therapeutic approaches.

Hodgkin lymphoma - Clinical

BASELINE LEUKOCYTE AND EOSINOPHIL COUNTS PREDICT OUTCOME IN RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS TREATED WITH PD1 INHIBITION

I. Hude[1,2,*], S. Sasse[2], P.J. Broeckelmann[2], B. von Tresckow[2], J. Momotow[2], A. Engert[2], S. Borchmann[2]
[1]Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia, [2]German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (r/r) classical Hodgkin lymphoma (cHL), not all patients achieve a lasting response, with few complete remissions (CR) observed. Thus, identification of predictive biomarkers is important. Recently, two models using readily available differential blood count parameters have been suggested to predict outcome in melanoma patients treated with immune checkpoint inhibition.
Aims: In this study, we aimed to identify baseline differential blood count parameters associated with response and progression free survival (PFS) in r/r cHL patients treated with anti-PD1 antibody nivolumab.
Methods: We retrospectively investigated baseline differential blood count parameters and their association with response and progression free survival (PFS) in 30 r/r cHL patients treated with the anti-PD1 antibody nivolumab. All 30 patients had previously received multiple lines of treatment, including treatment with high dose chemotherapy followed by autologous stem cell transplant (ASCT) for r/r disease; the median number of prior treatment lines was 5 (2-11) and 21 patients received prior brentuximab vedotin. To investigate the association of baseline blood count parameters (white blood cell count (WBC), relative monocyte count (RMC), relative neutrophil count (RNC), relative lymphocyte count (RLC) and relative eosinophil count (REC)) with outcome after PD1 inhibition, we used the last differential blood count performed immediately prior to the first received dose of nivolumab.
Results: RMC, RNC and RLC did not have a prognostic impact on PFS, whereas higher WBC ≥ 7.78x10³/µl and lower REC<1.7% were associated with worse PFS in both univariate and multivariate analysis. We constructed a simple score to prognosticate PFS. By adding 1 point each for WBC ≥ 7.78x10³/µl and REC<1.7% to the score, we could clearly differentiate a low (score=0), intermediate (score=1) and high risk (score=2) group for disease progression (p<0.001). Only one PFS event occurred in the best prognostic group (n=10, median PFS (days): NA]) whereas 5 out of 11 patients in intermediate (median PFS (days): 365 [129-NA]) and 7 out of 9 patients in high risk group progressed (median PFS (days): 197 [50-NA]). Evaluation of best response achieved according to the initial risk score showed a trend towards higher CR-rates in low risk group, but was not significant.

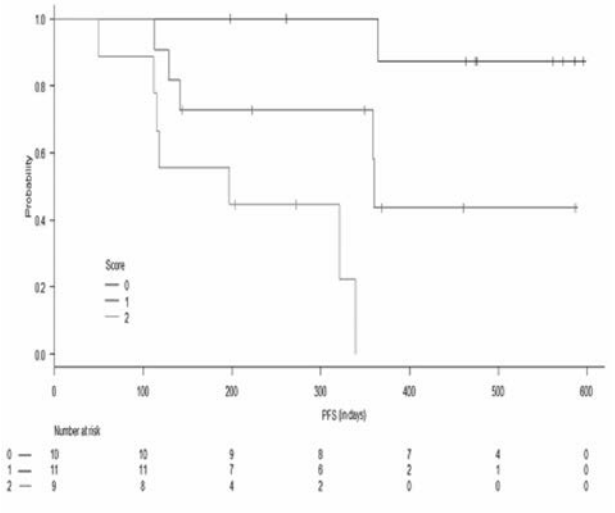

Figure 1.

Summary/Conclusions: Our simple prognostic model, mainly characterized by a normal to high REC, robustly discriminates three risk groups for PFS. Almost all patients in the low risk group achieved a durable remission without disease progression throughout the study period, despite often achieving just a partial response. In contrast, high-risk patients often progressed quickly despite initially achieving a partial or complete response. Further validation of this score which is easily available from routine clinical parameters in a larger cohort of patients and further investigation of its potential predictive impact is needed. Moreover, efforts to clearly understand a possible mechanistic role of eosinophils in cHL patients treated with PD1-inhibiton are warranted.

Background: The prognosis of HL primarily depends on clinical stage (CS) as well as limited-stage risk classification schemes and the International Prognostic Score (IPS), both of which delineate further prognostic subgroups within stages. B_2m is a well-established prognostic factor for several hematologic malignancies, but its role in HL is yet controversial. Between 1993 and 2016, several reports from other groups have yielded heterogenous results in small-to-medium-sized patient series of no more than 220 patients, frequently under variable treatment.
Aims: Our aim was to investigate the prognostic significance of serum b2m levels in HL.
Methods: We analyzed 864 patients with HL treated with ABVDeq CT/CMT (1990-2016) and selected solely based on the availability of pretreatment b_2m levels. B_2m [P1] levels (upper normal limit 2.4mg/L) were analyzed according to other baseline features and prognostic factors as well as according to the outcome: Freedom From Progression (FFP) was defined as time between treatment initiation and treatment failure (primary refractoriness, PR with switch to alternative CT or relapse); deaths of unrelated causes were censored. Overall Survival (OS) was measured from treatment initiation to death of any cause. ROC curves and sequential cut-offs (1.8-3.5 by 0.1 increments) were used to explore the potential impact of b_2m on FFP and OS.
Results: The median follow-up for currently living patients was 88 months. *Univariate Analysis:* FFP was significantly inferior in patients with higher b2m at all tested cut-off points. At 2.4mg/L (normal *versus* elevated) the 10-year FFP was 81% *vs* 71% (p=0.003). However, the best cut-off was the observed median value of this series, calculated at 2.1mg/L, with 10-year FFP rates of 84% *vs* 71% (p<0.0001). In early stages (IA/IIA) significant results were obtained at cut-offs between 1.8 and 2.1mg/L. The best cut-off was 1.9mg/L, a close approximation of the median b_2m level of early stage patients, with 10-year FFP of 89% *vs* 78% (p=0.003). In advanced stages, none of the cut-offs yielded statistically significant results (borderline at 2.0mg/L; 10-year FFP 77% *vs* 67%, p=0.057). *Multivariate Analysis:* B_2m levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs [hazard ratio (HR) 1.78, p=0.001 and 1.41, p=0.04 respectively) in the whole series of 864 patients. In early stages, b2m was a significant predictor of FFP at the cut-offs of 1.9mg/L and 2.1mg/L (HR 2.00, p=0.01 and 1.83, p=0.02 respectively), but only borderline at the cut-off of 2.4mg/L (HR 1.65, p=0.07). In advanced stages, b2m emerged as an independent prognostic factor for FFP at the cut-off of 2.2mg/L (HR 1.59, p=0.046 despite the lack of significance in univariate analysis), but was not significant at the 2.4mg/L cut-off. The 10-year OS was lower in patients with high b_2m levels (10-year rates 91% *vs* 76%, p<0.0001).
Summary/Conclusions: Higher serum b_2m emerged as a significant independent predictor of FFP at the cutoff of 2.0mg/L for the whole series and 1.9mg/L for early-stage patients. The prognostic significance in advanced stages was weaker (best cut-off 2.2mg/L). Serum b_2m was also highly predictive of OS. This is by far the largest report on the prognostic significance of b_2m in HL, highlighting the significance of the cut-off used to define "high" levels. Its significance is more pronounced in early stage disease. The optimal cut-off for the evaluation of serum b_2m in HL may be stage-dependent and appear to lie between 1.9 and 2.2mg/L, thus performing better than a "normal *versus* high" evaluation (cut-off 2.4mg/L).

E1121

THE PREDICTIVE VALUE OF INTERIM PET-CT IN ELDERLY PATIENTS WITH HODGKIN LYMPHOMA

O.S. Bentur[1,*], D.J. Eldad[2], E. Paran[3], D. Lavie[4], B. Nachmias[4], N. Dally[5], O. Gutwein[6], Y. Herishanu[7], N. Sarid[1], C. Perry[7], I. Avivi[7]

[1]Hematology, Tel Aviv Sourasky medical center, Tel Aviv, [2]Hematology, Rambam medical center and Rappaport Faculty of Medicine, Technion, Haifa, [3]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, [4]Hematology, Hadassah medical center and Faculty of Medicine - Hebrew University of Jerusalem, Jerusalem, [5]Hematology, Ziv medical center and Bar Ilan University Faculty of Medicine, Zefat, [6]Hematology, Assaf Harofe medical center and Sackler Faculty of Medicne - Tel Aviv University, [7]Hematology, Tel Aviv Sourasky medical center and Sakcler Faculty of Medicine - Tel Aviv University, Tel Aviv, Israel

Background: Hodgkin lymphoma (HL), a disease of mostly young patients, also peaks in the elderly. Despite the profound improvement in the clinical outcome of young patients, in the elderly, 5 year overall survival (OS) is estimated at only 40-55%. Interim PET-CT (iPET), known to be highly predictive for progression free survival (PFS) in young patients with HL, has not been sufficiently validated in elderly patients, nor have many other outcome predictors in HL of the elderly.
Aims: The objective of the present study was to evaluate the significance of iPET in elderly patients with HL.
Methods: All consecutive patients (age ≥60) diagnosed with HL between 1998-2016 were retrospectively reviewed in this multi-center study. Baseline characteristics as well as PET-CT results at diagnosis, interim analysis and end of treatment (EOT) were recorded and analyzed. PET-CT results were classified as no evidence of disease (NED), partial response (PR), stable disease (SD) and progressive disease (PD).
Results: Ninety five patients from 5 centers were identified. Median age was 71 (range 60-89) years. Subtype was nodular sclerosis in 48% and mixed cellularity in 23%. Sixty three (69%) patients had advanced disease and mean international prognostic score (IPS) was 3.5±1.4. Fifty nine (63%) patients received first line treatment with ABVD, in 13 (14%) chemotherapy was followed by involved field radiotherapy. At EOT, sixty seven (82%) patients achieved CR, 6 (7%) achieved PR, 10 (11%) were primary refractory and 2 (2%) died during treatment. Fifteen (16%) patients experienced relapse. Five year PFS and OS were 56% and 78%, respectively. ABVD treated patients had 5 year PFS and OS of 59% and 82% as opposed to 48% and 68% for all other regimens, but these differences were not statistically significant. Seventy two (76%) patients had undergone both iPET and EOT-PET. 50 patients had NED on iPET, 20 had PR, 1 SD and 1 PD. NED EOT-PET was achieved in 47/50 (94%) patients who had NED iPET, 12/20 (60%) patients who had PR iPET and none of the patients with SD/PD iPET (p<0.01). In patients with either NED or PR on iPET, relapse occurred in 11 (15%) patients and 5 year PFS and OS were 62% and 85%, respectively. The 5 year PFS of these patients differed according to the depth of response on iPET - 69% *vs* 45%, (p=0.02, fig.1) in patients achieving NED *vs* PR, while 5 year OS did not reach statistical significance, 90% *vs* 71% (p=0.08). Restricted analysis, evaluating only 59 patients who were treated with ABVD, showed similar results with 94% of NED iPET *vs* 45% of PR iPET achieving NED on EOT-PET (p<0.01). Outcome differed according to the depth of response in iPET with 5 year PFS rates of 74% *vs* 34%, in patients achieving NED *vs* PR, respectively (p<0.01). 5 year OS rates were 92% *vs* 76%, in patients achieving NED *vs* PR (p=0.1).

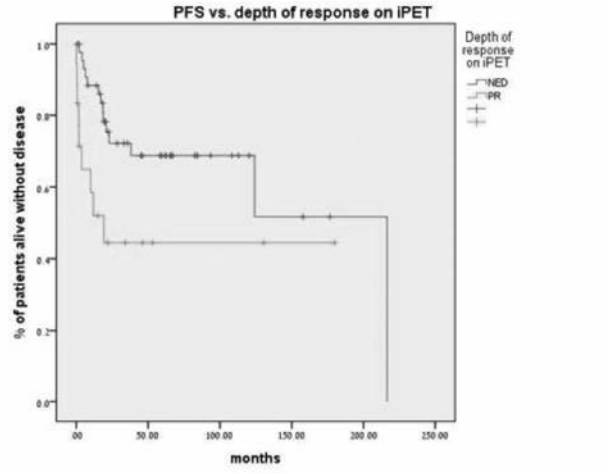

Figure 1.

Summary/Conclusions: We present a cohort of elderly patients with HL, most were treated with ABVD. Outcome was comparable or even superior to previously published cohorts. Traditional outcome measures for HL have not been extensively validated in the elderly. iPET and EOT-PET, known to be highly predictive for PFS in young HL patients, appeared to be highly predictive in elderly individuals. The improved prognosis, suggested by our results, may be related to the high rate of iPET which was used in this cohort. The importance of this tool in HL in the elderly is emphasized by the diminished prediction power of the traditional outcome measures in elderly HL patients.

E1122

HIGH-DOSE BENDAMUSTINE PLUS BRENTUXIMAB COMBINATION IS EFFECTIVE AND HAS A FAVOURABLE TOXICITY PROFILE IN THE TREATMENT OF REFRACTORY AND RELAPSED HODGKIN LYMPHOMA

C. Cerchione[1,*], M. Di Perna[1], R. Della Pepa[1], N. Pugliese[1], F. Pane[1], M. Picardi[1]
[1]Hematology, Ematologia e Trapianto/AU Federico II, Napoli, Italy

Background: The management of patients with refractory or relapsed Hodgkin lymphoma (HL), especially after autologous stem cell transplantation (ASCT), remains controversial. Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosage and the possible combinations for a synergistic effect. Brentuximab Vedotin is a CD30-directed antibody-drug conjugate, currently approved for the treatment of relapsed or refractory HL.
Aims: The objective of this retrospective observational trial was to evaluate efficacy and safety of salvage cytotoxic regimens in patients with refractory and/or relapsed HL. Three different regimens were evaluated.
Methods: From May 2011 to December 2016, 32 consecutive patients (19 M/13 F) with a median age of 31.7 years (range, 16-73) received a salvage regimen after failure of ASCT. Patients were by chance assigned to one of these three arms: standard dose bendamustine (90mg/sqm) days 1 and 2 plus standard DHAP schedule (every 4 weeks) x 3 cycles (Arm A, n= 10 cases), brentuximab single agent 1.8mg/kg (every 3 weeks) x 4-8 cycles (Arm B, n= 11 cases), high dose bendamustine (120mg/sqm) days 1 and 2 plus brentuximab 1.8mg/kg (day 3) x 4-6 cycles (Arm C, n= 11 cases). Each cycle in arm C was repeated every 28 days and growth factor support was systematically administered, in association with antimicrobial prophylaxis. The treatment efficacy in each arm was evaluated according to Revised Response Criteria for Malignant Lymphoma by Cheson *et al.* Any adverse event occurred was recorded and classified for type and grade using NCI-CTCAE criteria (v 4.0).
Results: In arm A, the overall response rate (ORR) was 40% (4/10 patients), with 4 (40%) complete remission (CR) and 6 (60%) progressive disease (PD). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (40%) and bone marrow aplasia in 1 patient (10%); extra-hematological toxicity was gastrointestinal toxicity of grade 2 in 6 patients (60%) and grade 1 in 3 patients (30%), In arm B, ORR was 63.6% (7/11 patients), with 5 (45%) CR, 2 (18%) partial response (PR) and 4 (36%) PD. Hematological toxicity was grade 2 neutropenia in 4 patients (36%), extra-hematological toxicity was grade 3 neuropathy in 2 patients (18%), In arm C, ORR was 100% (11/11 patients), with 11 CR followed by SCT (second autologous transplant, 6 cases; and haploidentical transplant, 5 cases) with persistence of complete remission in all patients at a median follow-up of 33.4 months (range, 12-60). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (36.3%); extra-hematological toxicities were increase of transaminase (grade 2) in 3 patients (27%) and cytomegalovirus (CMV) reactivation in 2 patients (18%), treated successfully with valganciclovir. Three patients had fever during infusion at first cycle, together with a skin rash, managed with corticosteroid injections, and a successful antihistamine plus corticosteroid prophylaxis in the next cycles of treatment.

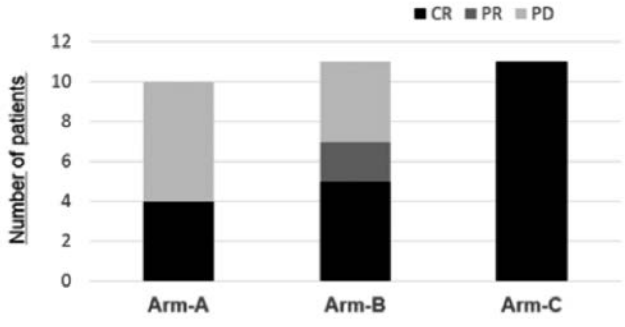

Figure 1.

Summary/Conclusions: High-dose bendamustine plus brentuximab has shown relevant efficacy and a relatively good safety profile in a setting of heavily pretreated patients with HL. Adequate monitoring of CMV reactivation is recommended. This combination could be considered as a bridge to second autologous or allogenic SCT. However, these results should be validated by controlled and prospective studies involving larger number of patients.

E1123

NEED OF HORMONAL THERAPY TO PRESERVE FEMALE FERTILITY IN HODGKIN E NON-HODGKIN LYMPHOMA PATIENTS FOLLOWING CHEMOTHERAPY: A TWO-CENTER SURVEY

O. Annibali[1,*], V. Tomarchio[1], M. Sampaolo[2], M. Tafuri[1], S. Cacciagiù[2], M. Becilli[1], D. Lupascò[2], M. Ciccarone[3,4], G. Gini[2]
[1]UOC Hematology, Stem cell Transplantation, University Campus Biomedico,

Rome, [2]Clinica di Ematologia, AUO Ospedali Riuniti Università Politecnica delle Marche, Ancona, [3]associazione Onlus Gemme dormienti, [4]Unità di ginecologia, Ospedale San Carlo di Nancy, Rome, Italy

Background: In the last decades, Hodgkin and Non-Hodgkin Lymphoma (HL-NHL) therapies have resulted in high cure rates and increased survival. However, younger patients (< 50 years), experienced severe late toxicities, such as, gonadal toxicity that can result in permanent sterility.
Aims: to evaluate different aspects of fertility (menstrual status, pregnancy, and menopause) in women with HL and NHL in reproductive age before and after chemotherapy.
Methods: By a phone interview we administered a questionnaire to the patients. The interview was composed of questions concerning reproduction (pregnancies, menses and abortion) and also menopausal status. The analyses were made using data collected in a cohort 109 women patients from two Italian hematologic centers. Statistical analysis was carried out in Graphpad® system, data were compared by the chi-square (P value <0.05 was consider to be statistically significant)
Results: the median age (in years) at the time of the treatment was 31 (range 16-49), 69/109 (63%) had HL and 40/109 (37%) NHL, 74/109 [ES1] (64%) of the patients had a stage I-II. All HL patients were treated with ABVD, whereas the remaining NHL patients were treated with R-CHOP (20%) or similar regimens (16%), respectively. Radiotherapy was delivered to the 62/109 (57%) of the sample. Complete Remission (CR) was obtained by the 101/109 (93%) and only 16/101 (16%) relapsed. Considering the gynecologic history of the patients there were no statistically significance difference between the regularity of menses and the event of an abortion pre and post treatment. As for pregnancies, 35% of patients had children before therapy and 17% after. Among these 109 patients, 68/109 (62%) received gonadotropin-releasing hormone (GnRH) analogues and/or oral contraception, while 41 (38%) were not treated with hormonal therapy. Among the 68 patients who received hormonal therapy regular menses recovered in 61/68 (90%) while in those of the control group a recover of menses was observed in 20/41 (48%). This difference was statistically significant (P<0.05). The same was observed as for early menopause. In this case excluding patients who had a natural menopause, a lower cases of early menopause was observed in those who received hormone therapy (8/65, 12% *vs* 23/38, 61%; P<0.05). Considering only the 81/109 (74%) patients who had regular menses after chemotherapy, 61/81 (75%) received hormonal therapy and 20/81 (25%) were not treated with hormonal therapy. Before treatment for lymphoma, 16% of patients belonging to the hormonal group had pregnancies *versus* 45% of the control group (P<0.05). Following therapy, pregnancies were observed in 23% of those receiving hormonal therapy *vs* 5% of the control group (P<0.05).
Summary/Conclusions: The use of hormonal therapy is fundamental not only to favor of pregnancies and motherhood but in particular to avoid the consequences of an irregular cycle or an early menopause with its symptoms and clinical implications.

E1124

25(OH)VITAMIN D SERUM LEVELS IN HODGKIN LYMPHOMA

A. Cuccaro[1,*], E. Galli[1], F. Visconti[1], I. Zangrilli[1], F. Corrente[1], S. Bellesi[1], U. Basile[2], S. Annunziata[3], V. Rufini[3], M. Balducci[4], F. D'Alò[1], S. Hohaus[1]
[1]Hematology, [2] Laboratory Medicine, [3]Nuclear Medicine, [4]Radiotherapy, Catholic University of Sacred Heart, Rome, Italy

Background: Vitamin D has pleiotropic effects on cellular differentiation, proliferation, apoptosis and angiogenesis in addition to maintaining serum calcium and skeletal homeostasis. Several studies suggest that low serum 25(OH)D levels may be associated with inferior outcome in solid tumors as colorectal and breast cancer, and in Non-Hodgkin lymphomas [Drake *et al*, J Clin Oncol 2010; 28:4191] as diffuse large B cell lymphoma [Bittenbring *et al*, J Clin Oncol 2014; 32:3243], and follicular lymphoma [Kelly *et al*, J Clin Oncol 2015; 33:1482]. 25(OH)Vitamin D levels have not been reported for Hodgkin Lymphoma (HL).
Aims: To evaluate vitamin 25(OH)D levels in patients with HL and analyze for associations with clinical characteristics and clinical outcome.
Methods: We studied 76 patients with cHL (40 females, 36 males, median age 33 years), diagnosed at our Institution between 2014 and 2016. Treatment consisted in ABVD (66 patients), BEACOPP d.e. (7 patients), and COPP (2 patients). One patient received only radiotherapy. Serum samples for vitamin D quantification were collected before the first day of chemotherapy. 25(OH)D was measured in patients' sera using a standardized clinical assay, the DiaSorin LIAISON 25-OH Vitamin D TOTAL. 25(OH)D levels were defined according to three conditions: deficient (<10 ng/ml), insufficient (10-30 ng/ml), and sufficient (>30 ng/ml).
Results: The median 25(OH)D level at diagnosis was 20.6 ng/ml (range: 5.5 to 42.3 ng/ml). 25(OH)D levels were considered normal in 8 (10.5%) patients, insufficient in 59 (77.5%) patients, and deficient in 9 (12%) patients. Looking at patient characteristics, 25(OH)D levels were lower in patients with age over 60 years (p=0.002), reduced performance status (ECOG>1) (p=0.01), stage IV disease (p=0.01), and IPS (Hasenclever) score >2 (p=0.002). Furthermore levels were lower in patients with hemoglobin below 10,5 g/dl (p=0.06). No association was found with gender, albumin level, B symptoms. In addition, there was a significant seasonal variation, with 25(OH)D levels to be lowest in the first quarter and highest in the third quarter (p=0.03). FDG-PET evaluation after 2 cycles of chemotherapy according to the 5-point Deauville scale was available in 66 patients. Vitamin D levels were not associated with interim PET response. With a median of 12 months follow-up of patients is still short. Patients with deficient levels (n=9) had a significantly worse PFS than patients with higher levels (n=67) (p=0.002). The probability of progression-free survival at 12 months was 87% (95% C.I., 75-94%) in patients with 25(OH)D levels>10 ng/ml, while patients with levels<10 ng/ml had a 12 months PFS of 47% (95% C.I., 12-76%). We included 25(OH)D levels, IPS (that includes age, stage and hemoglobin level), ECOG and season in a multivariate Cox analysis. Deficient 25(OH)D level had a borderline significance (HR 5.65, 95% C.I.,0.98-32.55; p=0.05).
Summary/Conclusions: 25(OH)Vitamin D serum levels are frequently low in patients with Hodgkin Lymphoma and are associated with patient-related and disease-related characteristics. Our preliminary analysis suggests that low 25(OH)D levels might be associated with worse prognosis.

E1125

NODULAR LYMPHOCYTE PREDOMINANT HODGKIN LYMPHOMA: A NEW RISK ADAPTED TREATMENT STRATEGY BASED ON RITUXIMAB

R. Della Pepa[1,*], M. Picardi[1], C. Giordano[1], I. Zacheo[1], N. Pugliese[1], C. Cerchione[1], F. Pane[1]
[1]Hematology, Federico II University, Naples, Italy

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare variant of Hodgkin's lymphoma (HL), that only accounts for 5% of all HL. Due to its rarity, consolidated and widely accepted guidelines of treatment still lack for this type of HL. Due to NLPHL cells expression of CD20, targeted therapy with Rituximab (R), a chimeric anti-CD20 monoclonal antibody, has been explored as a treatment option.
Aims: This study analyzed two different risk-adapted therapeutic strategies to cure patients newly diagnosed with NLPHL. The aim was to compare the efficacy and safety of the conventional chemotherapy plus irradiation *versus* the R-including treatment of patients with NLPHL.
Methods: Within a retrospective study, we collected the medical records of 24 consecutive adult patients with NLPHL, taken from the total of 484 patients with HL, who referred to our institution from 1 October 2001 to 31 July 2014. According to our institutional guidelines, the 12 patients diagnosed from October 2001 to November 2007 received a treatment based on ABVD with/without involved-field radiotherapy (IFRT). Treatment was modulated according to the stage. The 9 patients with stages I and II received 4 courses of ABVD plus IFRT, while 3 patients in stages III or IV received 6 cycles of ABVD. The subsequent 12 patients (diagnosis from December 2007 to July 2014) received R (375mg/m^2) alone or combined with ABVD. The stage-adapted strategy of therapy was applied for these patients, as well. The 5 patients with early favourable disease, according to the stage and baseline EORTC risk factors, received R as single agent (once per week for four consecutive weeks) followed by R maintenance (MR) (once every three months for 2 years); the 2 patients with early unfavorable stage were treated with R (once per month on day 1) plus 4 cycles of ABVD, while the remaining 5 advanced stage patients received R (on day 1 and 15) plus ABVD for 6 cycles. The primary end-point was DFS rate, and secondary end-points were ORR and treatment-related toxicity evaluation.

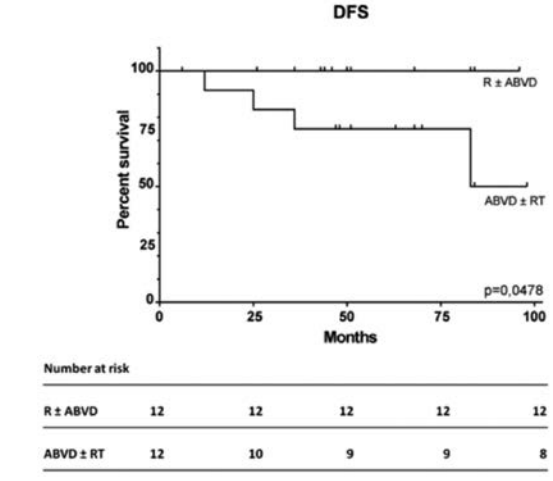

Figure 1.

Results: At final restaging, 4 weeks after the cycle of treatment or completion of IFRT, 23/24 patients (95.8%) were in CR while one patient showed refractory disease and was addressed to rescue therapy with autologous hematopoietic

stem cell transplantation (ASCT). Patients treated with R alone or R+ABVD had better DFS (p=0.04) than those treated with ABVD with/without IFRT. Specifically, the year Kaplan-Meier estimates for DFS were 100% for the R treated group *versus* 50% for those treated with ABVD with/without IFRT. Four patients in the latter group, showed insufficient response to the therapy: 1 refractory disease in the early stage group and 3 recurrent diseases in the advanced stage group were recorded. The median follow-up time of the entire cohort of patients was 4.3 years (range, 0.5-8.2 years). Over the study period, one patient died for infectious pneumonitis due to severe neutropenia following the last cycle of R-ABVD. Of the 9 patients treated with addition of IFRT, adverse events regarded mainly thyroid (4), bone (2), lung (1) and salivar glands (1). Nobody developed a secondary malignancy.

Summary/Conclusions: Our results confirm the value of R in NLPHL and show that R induction and maintenance combined with chemotherapy only in the presence of risk factors or in more advanced stages give excellent treatment results respect the conventional radio-chemotherapy either in term of ORR and of DFS while sparing long term toxicity usually seen in patients affected by classical HL who receive chemo and irradiation.

E1126

CASE-BASED LEARNING IN CONTINUING EDUCATION: IMPROVING HEMATOLOGIST/ONCOLOGIST EVIDENCE-BASED DECISIONS FOR PREVENTING HOGDKIN LYMPHOMA POST-TRANSPLANT RELAPSE

P. Repetto[1,*], C. Moskowitz[2]
[1]Oncology, Medscape, Groveville, [2]Oncology, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Several prognostic factors have been identified as associated with a higher rate of relapse after autologous stem cell transplant (ASCT) for patients with Hodgkin lymphoma (HL). Due to the rarity of this disease, many hematologists/oncologists (hem/oncs), especially those in the community setting, lack experience in correctly identifying patients who may be at risk of post-transplant relapse. Proper risk assessment and understanding of treatment options in the pre- and post-transplant setting are critical to ensure optimal longer progression-free survival for qualified patients.

Aims: Underlying clinical practice gaps and educational needs were identified and a study was conducted to determine whether an online, case-based educational intervention could improve knowledge, competence, and confidence of hem/oncs in managing patients with HL.

Methods: The educational format presented patient case scenarios (2) followed by a series of 4-5 questions that "tested" learner knowledge and competence before delivering the education focused on the optimal approach to the case using evidence-based medicine. Case questions assessed degree of patient risk for disease relapse or progression prior to ASCT and consolidation strategies, taking into consideration patients' prior received therapies. To assess educational effectiveness, participants served as their own controls by responding to a sample of same questions again after (post-assessment) exposure to the content. For all questions combined, the McNemar's chi-square test assessed differences from pre- to post-assessment. P values are shown as a measure of significance; P values <.05 are statistically significant. Cramer's V calculation determined the change in proportion of 184 participants who answered questions correctly from pre- to post- assessment and who qualified for the study.

Results: At post-assessment, there was a large effect to the education (V=0.442), indicating a sizable improvement in evidence-based choices and significant improvement in knowledge, competence, and confidence related to managing patients with HL, including: 138% relative improvement regarding the implications of type and number of prognostic factors on risk of HL relapse and benefit of consolidation brentuximab vedotin after ASCT (*P*<.001); 101% relative improvement in knowledge that a higher rate of relapse after ASCT is associated with a CR duration of less than 1 year, extranodal disease at relapse, and the presence of symptoms at relapse (*P*<.001); 5% relative improvement in knowledge regarding the efficacy of brentuximab vedotin in relapsed/refractory HL after ASCT (*P*<.001); Responses to a self-efficacy question indicated that 42% of hematologists became more confident in managing a patient on consolidation therapy for HL after participating in the education.

Summary/Conclusions: This study demonstrated the success of an online, case-based format using a predisposing pre/post assessment was effective in improving the evidence-based practice patterns of hem/oncs in the management of patients with HL. Despite the marked improvement in knowledge, competence, and confidence, hematologist education needs specific to accurate risk assessment, treatment selection, and adverse effect monitoring remain. The education gaps uncovered during this intervention and the evolving treatment landscape outside of the United States lay a foundation for future global education initiatives to bridge education gaps in HL.

E1127

QUANTITATIVE PET PARAMETERS PREDICTS OUTCOME IN PATIENTS WITH HODGKIN'S LYMPHOMA

I. Kriachok[1,*], O. Novosad[1], I. Pastushenko[1], T. Skrypets[1], T. Kadnikova[1], I. Tytorenko[1], E. Kushchevyy[1], K. Ulianchenko[1], K. Filonenko[1], Y. Stepanishyna[1], Y. Kmetyuk[2], O. Karpova[2], L. Mykhalska[3], O. Kindrakevych[3], G. Pylypenko[4], E. Lukjanec[4], V. Duma[4], V. Kozlov[5], L. Batyuk[5], O. Ryzhak[5], N. Strembitska[5], H. Chikalova[5], M. Chupryna[5], I. Kozlov[6]
[1]Oncohematology, National Cancer Institute, [2]Radiology, [3]Hematology, Clinical Hospital "Feofaniya", Kiev, [4]Hematology, Regional Oncology Center, Cherkassy, [5]Hematology, Regional Clinical Hospital, [6]Hematology, National Medical University, Odessa, Ukraine

Background: Positron emission tomography [18F] fluorodeoxyglucose (FDG-PET) has emerged as the standard response assessment after 1st line therapy for classical Hodgkin's lymphoma (HL). Quantitative PET parameters are not well established as a predictive factor for disease progression in HL.

Aims: Thus, the aim of this study was to test the hypothesis that tumor burden characterized by mean standardized uptake value (SUVmean), maximum SUV (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) could be independent prognostic factors.

Methods: We analyzed the relation of absolute value PET parameters, negative predictive value (negative PET scan and no treatment failure, NPV) and positive predictive value (positive PET scan and treatment failure, PPV) with event-free survival (EFS) or overall survival (OS). Quantitative PET parameters of the baseline (PET-1), interim (PET-2) and end of treatment (PET-3) PET-CT scans were investigated in the retrospective study. MTV was computed by using the 41% maximum SUV thresholding method, and the optimal cut-off for survival prediction was determined.

Results: Thirty one patients with HL with a stage I-II–51.6%, III-IV–48.4% consecutively admitted from April 2009 to December 2016, by 5 Ukrainian hematological centers were included in the analysis. Patients were staged at baseline, after 2-4 cycles of chemotherapy with PET/CT and at the end of chemotherapy. All patients were treated with ABVD, BEACOPP-14/esc. All 31 patients achieved CR or PR and 67,7% had a negative PET-2, while 16,3% had a positive PET-2. Patients with negative PET-2 and positive PET-2 had CR rates of 64,5% and 12,1%, respectively, which yielded a PPV of 26% and NPV of 74%. ROC analysis revealed that PPV and NPV are an important markers associated with EFS in patients with HL (Se=100%; Sp=100%; AUC=1.0). 3-year EFS was 100% for NPV patients and 12% for PPV patients, which was statistically significant (p<0.01). 3-year OS was 100% and 75% for NPV and PPV patients, respectively (p<0.01). Quantitative parameters at PET-1 and PET-2 were not statistically significant in predicting clinical outcome in this study. This may be due to the small sample size in our study. PET-3 was negative in 67,7% cases. ROC analysis showed that ∑MTV at PET-3 is an important marker associated with reduced EFS in patients with HL (Se=75%; Sp=100%; AUC=0.97, p<0.0001). 3-year EFS was 89% and 25% in patients with ∑MTV <4.75 and ∑MTV >4.75, respectively (p=0.005). Also, ROC analysis revealed that TLG at PET-3 was associated with decrease EFS in patients with HL (Se=75%; Sp=100%; AUC=0.97, p<0.0001). Multivariate analysis confirmed ∑MTV and TLG at PET-3 were the only significant variables for EFS with HRs of 1.07 [95% confidence interval(CI) 1.0–1.15, p=0.003] and 2.9 [95% (CI)0.9-1.03, p=0.05), respectively. The PET-3 SUVmax and SUVmean were not statistically significant in predicting EFS.

Summary/Conclusions: Quantitative PET parameters may play a predictive role for identifying patients at high risk of treatment failure. These results should be evaluated prospectively in larger cohorts with longer follow-up.

Background: Ibrutinib, a first-in-class, oral, covalent inhibitor of Bruton's tyrosine kinase, has demonstrated robust clinical activity and is approved in various B-cell non-Hodgkin's lymphomas. To assess the efficacy and safety of ibrutinib in patients (pts) with follicular lymphoma (FL), the DAWN study (FLR2002, NCT01779791) investigated single-agent ibrutinib in chemoimmunotherapy (CIT)-refractory FL pts. Ibrutinib may exert immune-modulatory effects on T-cell activity via inhibition of ITK, a key regulator of T-cell activity, possibly through inhibition of T-helper 2 (Th2)-polarized CD4 T-cells and activation of Th1 cells (Dubovsky, *et al. Blood* 2013). Here, we describe the effect of ibrutinib treatment on T-cells and cytokines in pts in the DAWN study.
Aims: To determine the effect of ibrutinib on circulating T-cells, chemokines, and cytokines in ibrutinib-treated CIT-refractory FL pts.

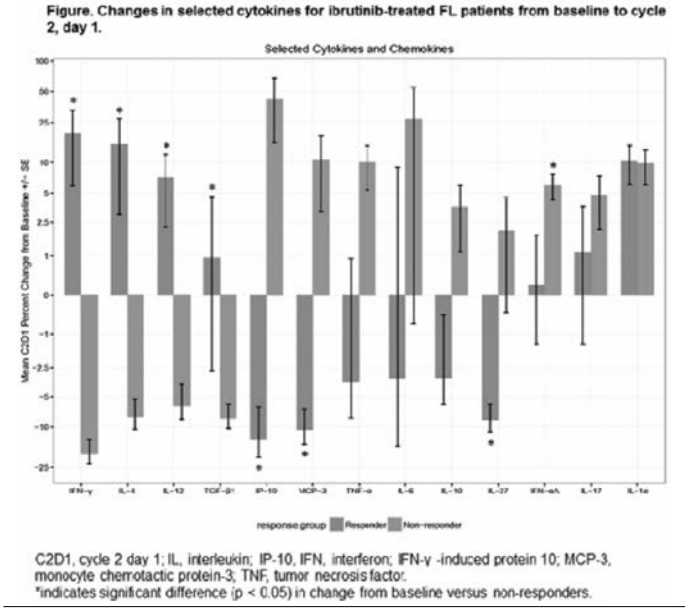

Figure 1.

Methods: The DAWN study was an open-label, multicenter, single-arm, phase 2 study of ibrutinib in pts with CIT-refractory (*i.e.*, ≥2 prior lines of therapy and progressive disease [PD] ≤12 months after last dose of a CIT regimen). All pts received ibrutinib (560mg QD) on a 21-day cycle until PD or unacceptable toxicity. The primary end point was Independent Review Committee (IRC)-assessed overall response rate (ORR) (complete response [CR] + partial response [PR]). Flow cytometry assessed T-cell subsets in peripheral blood at baseline (C1D1) and at cycle 3 (C3D1) for 57 pts (14 responders and 43 nonresponders); cytokine and chemokine analyses were performed at C1D1 and at cycle 2 (C2D1) for 50 pts (21 responders and 29 nonresponders).
Results: Results from the DAWN study have been presented previously (Gopal A, *et al.* ASH 2016). Briefly, 110 pts with a median age of 61.5 years and a median of 3 prior therapies were enrolled. Ibrutinib achieved an ORR of 20.9% (CR rate, 10.9%) and a median duration of response of 19.4 months. Flow cytometry analysis revealed significant downregulation of CD4+CD25+CD127-T_{regs} at C3D1 in 14 responders (CR + PR, mean decrease 17 to 12.9% CD4, p=0.02) but not in 43 nonresponders (SD + PD, 11.5 to 10.4% CD4, p=0.17). From a large panel of inflammation-related cytokines and chemokines, some of the most significant changes at C2D1 were the Th1 cytokines interferon (IFN)-γ and interleukin (IL)-12, both of which were increased in responders but decreased in nonresponders (p=0.0025 and p=0.035, respectively; **Figure 1**). Conversely, the chemokines IFN-γ-induced protein 10 (IP-10) and monocyte-chemotactic protein 3 (MCP-3) were decreased in responders but increased in nonresponders (p=0.022 and 0.016, respectively).
Summary/Conclusions: Here we show immunomodulatory effects of ibrutinib in pts with CIT-refractory FL, which may be related to response to therapy. In responding pts at early time points, downregulation of T_{regs} was observed, along with increases in Th1-associated cytokines IFN-γ and IL-12. This shift in T-cell population may be linked to the antitumor response; in nonresponders, these cytokines were decreased but T_{regs} were not. Chemokine changes observed also indicate variation in chemoattraction of T-cells and monocytes/macrophages. These data suggest that immunomodulatory effects of ibrutinib could play a role in its antitumor activity in FL, so combinations with other immune-oncology therapies may prove beneficial.

E1130

DYNAMO: THE CLINICAL ACTIVITY OF DUVELISIB IN PATIENTS WITH DOUBLE-REFRACTORY SMALL LYMPHOCYTIC LYMPHOMA IN A PHASE 2 STUDY

P.L. Zinzani[1,*], N. Wagner-Johnston[2], C. Miller[3], S. Tertreault[4], F. Passamonti[5], S. Lunin[6], H. Youssoufian[7], J. Porter[7], S. Prados[7], I. Flinn[8]

[1]Institute of Hematology Serágnoli, University of Bologna, Bologna, Italy, [2]Siteman Cancer Center, Washington University, St Louis, [3]Saint Agnes Hospital, Baltimore, [4]Florida Cancer Specialists -Tallahassee, Tallahassee, United States, [5]University Hospital Ospedale di Circolo, Varese, Italy, [6]Florida Cancer Specialist, Fort Myers, [7]Verastem Inc, Needham, [8]Tennessee Oncology, Nashville, United States

Background: Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib in a double refractory iNHL population, which included 28 patients (pts) with small lymphocytic lymphoma (SLL).
Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety duvelisib.
Methods: DYNAMO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25mg BID in 28-day treatment cycles until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs), and changes in safety laboratory values. *Pneumocystis jiroveci* pneumonia (PJP) prophylaxis was mandated for all pts.
Results: 129 pts with iNHL were treated on study. Of these, 28 pts with SLL received duvelisib with a median duration of exposure of 9 mo. (range 6.5-12). Median age was 65 years; 68% were male. Most SLL pts had an ECOG performance status score at baseline of 0 (43%), followed by 1 (54%) and 2 (4%). Most SLL pts had either Stage 3 (25%) or Stage 4 (61%) disease at baseline. Median time from last anticancer therapy to first dose of duvelisib was 3 months. SLL pts received a median of 3 prior anticancer regimens (range: 1-18); 43% of pts received ≥4 prior anticancer regimens, 29% ≥6 regimens. The ORR for SLL pts was 68% (95% CI: 48, 84) per IRC assessment. All responses (19) were PRs. Four (14%) pts had a best response of SD and 3 (11%) pts had a best response of PD. 2 pts were unevaluable for response. Per Investigator assessment, the ORR was 79% (including 1 CR). Median time to IRC response was 1.9 months (range 1.4-5.5). 93% of pts had a reduction in nodal target

lesions. Among the 19 SLL pts with a response per IRC, the median DOR was 9.9 months. The median PFS among all SLL pts was 11.3 months, while the median OS was not reached. The estimated probability of survival at 12 months was 83.9%. Among all pts treated (n=129), AEs were mostly Gr 1-2. Most common ≥ Gr 3 AEs were transient cytopenias (neutropenia [23%], anemia [12%], and thrombocytopenia [10%]), and diarrhoea (15%). 4 SLL pts had SAEs that led to discontinuation of duvelisib: NSCLC, neuroendocrine carcinoma of the skin, pseudomembranous colitis, and pneumonia. Two SLL pts has a fatal AE, 1 pneumonia and 1 viral infection.
Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory SLL population (68% ORR, median DOR 9.9 mo., 93% with a reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy appears to have a favorable benefit-risk profile in double refractory SLL. Updated clinical data will be available at the time of presentation.

WALDENSTROM MACROGLOBULINEMIA: UK REAL WORLD EXPERIENCE
D. El-Sharkawi[1,*], H. Renshaw[1], M. Lunn[2], D. Hughes[3], A. Rismani[1], S. D'Sa[1]
[1]Cancer Division, University College London Hospital (UCLH), [2]Peripheral Nerve Service, National Hospital for Neurology and Neurosurgery, [3]Haematology, UCL, London, United Kingdom

Background: There are few randomised controlled trials in Waldenström macroglobulinaemia (WM) due to its rarity and indolent nature. As a result, there is no standard treatment approach and management is variable.
Aims: The aim of this retrospective study was to review "real world" management of WM in the UK and correlate this with survival outcomes.
Methods: All patients with a diagnosis of WM seen at ULCH between 01/07/2002 and 31/12/2016 were included. Patient characteristics, presenting features, lines of treatment, responses and overall outcome were recorded. IPSSWM where available, was calculated at time of first treatment. Survival was estimated using Kaplan-Meier analysis from time of first treatment and *P* values calculated using the log-rank test.

Figure 1.

Results: A total of 211 patients were identified (116 M/ 95 F), median age 60 yrs (range 34-89). Presenting symptoms included anaemia, n=33; neuropathy, n=19; fatigue, n=18; hyperviscosity symptoms, n=13; lymphadenopathy; n=5; progression frommgUS, n=5; B symptoms, n=5; other, n=28; unknown, n=55. Mutated MYD88 was seen in 59 of 72 cases analysed (82%). Of these 59 cases, 13 were CXCR4 mutated. IPSSWM was known in 150 cases of whom 64 were in low, 63 intermediate and 23 high risk groups. Median follow-up from first appointment was 64 months (range 0-394). The median number of lines of therapy was 2 (range 0-9). Dexamethasone, rituximab and cyclophosphamide (DRC) was given to 62 patients upfront, 52 had other cyclophosphamide containing regimens *e.g.* CHOP +/- rituximab, 29 had Chlorambucil-based regimen, 14 R-bendamustine, 15 fludarabine-based with a minority getting R-cladribine (5) or R-bortezomib (4), 9 patients had no treatment at data cut-off. Notably, DRC was given to 1 patient before 2009, 28% of patients between 2009 and 2013, and 41% from 2013. In the 149 cases with known responses to first line treatment, 11% achieved a CR (7 patients with R-CHOP, 4 DRC, 2 fludarabine containing regimen, and 3 patients other treatment), 63% PR/ VGPR, 21% no response or PD and 5% stopped due to toxicity. For the 52 patients who had DRC chemotherapy, median PFS was 61 months. Of those patients who had at least 3 lines of chemotherapy (n=62), median time between 1st and 2nd line treatment was 10 months and 3 months between 2nd and 3rd line. Transplants were performed on 28 patients after a median of 2 lines of chemotherapy. Median overall survival (OS) has not been reached in the 195 patients with available data. Stratifying by IPSSWM shows median OS for the low risk group has not been reached, 11 years for the intermediate risk and 9 years for the high risk group, *P*=0.29 (Figure). Patients had a significantly reduced OS if they developed Bing Neel syndrome or high grade transformation compared to other known complications of WM. Despite differences in chemotherapy strategies over the past two decades, there was no difference in outcome in patients treated before 2005, between 2005-2009, 2009-2013 and 2013 onwards. Of the 34 deceased patients, the cause of death was unknown in 3 cases, due to PD in 16 and other causes in 15 cases.
Summary/Conclusions: The management of patients with WM in this large case series reflects the variability of treatment given over time and also geographically. UCLH treats both a local and tertiary referral patient population, thus it is not completely typical. Survival data confirms the IPSSWM is likely to still differentiate patients into prognostic groups but the overall prognosis is better than when first published. With the advent of targeted therapies, it is imperative to perform randomised controlled trials and to collect data prospectively in order to elucidate the optimal management. To this end, a WM Biobank and Registry has been set up at our centre.

E1133

CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF INDOLENT NON-HODGKIN'S LYMPHOMA ASSOCIATED WITH HEPATITIS C (IL + C)
S. Lepkov[1,*], I. Subortseva[2], G. Tumyan [3], P. Zejnalova[3], O. Kolomejtsev[3], Y. Ryabukhina [3], A. Semenova[3], N. Kokosadze[3], N. Kupryshina[3], I. Komarov[3], O. Malikhova[3], O. Ettinger[1], S. Borisovskaya[1], I. Lazarev[4], V. Ivanova[4], R. Ivashhenko[5], A. Kovrigina[2], I. Nikitin[1], Y. Kemizh[6]
[1]Russian National Research Medical University named after N.I. Pirogov, [2]National Research Center for Haematology, [3]National Research Center for Oncology named after N.N. Blochin, [4]City Clinical Hospital named after C.P. Botkin, [5]City Clinical Hospital named after V.M. Buyanov, [6]City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: According to the WHO classification (2008) hepatitis C virus is one of the causesof non-Hodgkin lymphoma. The incidence of chronic hepatitis C (HCV) in patients with indolent B-cell non-Hodgkin's lymphoma (IL + C) is 15%. Diagnosis of hepatitis C related lymphoma (IL + C) is established in cases where the tumor tissue of patients express proteins of hepatitis C virus. These proteins could idefined by immunohistochemistry (IHC).
Aims: The aim of this work was evaluation of the results of treatment of IL associated with hepatitis C in comparison with a control group of patients with IL without viral hepatitis markers.
Methods: The study included 107 patients with indolent lymphoma who were identified in the blood markers of hepatitis C.
Results: Histological types were follicular lymphoma - 74%, marginal zone lymphoma - 32%. The age of patients ranged from 28 to 82 years (median 50). Men / women ratio was 1: 1. Stage I + II were in 3%, III stage was in 24% of patients, IY stage was at 73% of patients. Primary extranodal lymphoma was diagnosed in 33% of patients. Extranodal lesions: splenic lesion -in 53% of patients, liver injury - 21% of the patients, the bone marrow - 62% of patients. LDH ≥ 450 IU / l was at 76% cases, ALT ≥40 IU / l was at 82% of cases, albumin <35 g / l was at 31% of patients. 57 patients were treated with interferon and Ribavirinum as a first-line treatment. Treatment lasted for 2 years after reaching the antitumor effect. 50 patients were treated with immunochemotherapy (R-CHOP, R-CVP) as a first-line treatment. Antiviral therapy was effective in 88% patients, immunochemotherapy was effective in 64% of patients. Median progression-free survival in patients with IL + C treated with antiviral treatment was 42 months, in patients with IL + C treated with immunochemotherapy - 19 months (p=0.00001). Five-year overall survival was 67% and 32%, respectively (p=0.0003). It was diagnosed disease relapses after immunochemotherapy in 39 patients. All the patients in the second-line was received antiviral treatment. Response to the ongoing antiviral therapy was achieved in 77% of cases. Median progression-free survival in relapsed lymphoma was 31 months.
Summary/Conclusions: Antiviral therapy in first-line and relapse of disease surpasses all the indicators of efficiency of treatment IL + HCV. In this category of patients preferred option is to conduct anti-viral treatment.

E1134

90Y-IBRITUMOMAB-TIUXETAN AS FIRST-LINE CONSOLIDATION IN COMPLETE RESPONSE FOLLICULAR LYMPHOMA PATIENTS. SINGLE CENTER ANALYSIS AFTER SIX YEARS MEDIAN FOLLOW-UP
M. Andrade-Campos[1,*], N. Espinosa Lara[2], P. Lievano Segundo[3], L. Lopez[4], T. Baringo[3], P. Giraldo[5]
[1]Translational Research Unit - Hematology, IIS-Aragon. CIBERER., [2]Hematology, [3]Nuclear Medicine, Miguel Servet University Hospital, [4]Hematology, Hospital Royo Villanova, [5]Translational Research Unit - Hematology, IIS-Aragon. CIBERER. IISCIII, Zaragoza, Spain

Background: Follicular lymphoma (FL) accounts for around 22% of all non-Hodgkin lymphomas. His natural history is characterized by multiple relapses and progressively shorter response durations after every new line of therapy for this is desirable to offer the best first-line approach to each patient. In the current guidelines several first line options are included: immunotherapy (Rituximab (R) x4 or Lenalidomide+/- R), immunochemotherapy (CHOP, RCVP, Bendamustine + R), radioimmunotherapy for elderly patients. Moving forward, the consolidation with radioimmunotherapy or extended dose immunotherapy

(R every 8 weeks for 4 or 12 doses) still appears as an optional part of the therapy (NCCN V3.2016). Radioimmunotherapy with 90Yttrium-ibritumomab tiuxetan (90Y-IT) is available in our institution since 2006 and more than 100 patients have been treated with RIT since then. Here an institutional analysis focus in their use as consolidation is presented

Aims: To analyze the experience with 90Y-IT as a consolidation therapy in patients in CR after first-line therapy.

Methods: A retrospective analysis was performed including all the patients that have received RIT with 90Y-IT. Inclusion criteria were: patients 18 years or older with a grade 1-2a follicular lymphoma, RIT was received as a consolidation therapy in complete response (CR) after a first-line therapy. Demographic and follow-up data were included. International working group (IWG) criteria of response was used. Progression free survival (PFS) was calculated from the date of RIT to the date of a confirmed relapse according IWG criteria, overall survival (OS) was calculated from the FL diagnosis to the last contact.

Results: A total of 31 FL patients have received 90Y-IT been in CR after a first-line of therapy and were included for the study. Mean age at diagnosis was 61.2 (29-86) years with a female predominance (19, 61.3% *vs* 12, 38.7%). 80.6% (26) with ECOG 0-1 and 19.4 ECOG 2. A third of them (10, 32.3%) were diagnosed with low tumor burden (stage I-II), 2 (9.7) of them presented extra nodal infiltration (subcutaneous and gut) and 12 (38.7%) showed bone marrow infiltration demonstrated by flow cytometer or biopsy. There were no patients with bulky disease. Stages: I: 7 (22.6%), II: 3 (9.7%), III: 9 (29.1%), IV: 12 (38.7%). As first-line therapy the patients received: Rx4: 11 (35.5%) cases, R-Cyclophosphamide vincristine prednisone (COPx4): 3 (9.7%) cases and 17 (54.8) R-cyclophosphamide doxorubicin, vincristine and prednisone (R-CHOPx4-6). The median follow-up was 58.0 (10-107) months. During this time only 5 (16.1%) of patients have relapsed and need another therapy. None of the patients that have received R-CHOP+90Y-IT have relapsed; the relapsed patients received Rx4 (4) and R-COP (1). The median PFS after 90Y-IT has not reached, the mean was 83.3 (71.7-94.98) months, see Fig 1. Four (12.9%) patients have died, none of them were relapsed and the mortality was due other causes. The median OS was not reached, the mean was 95.8 (85.6-106.1) months. As long-term events one 82 years old patient developed a colon cancer after 67 months of RIT, one 72 years old female a breast cancer after 17 months of RIT and one 71 years patient amgUS after 24 months of RIT, none of them related with mortality events.

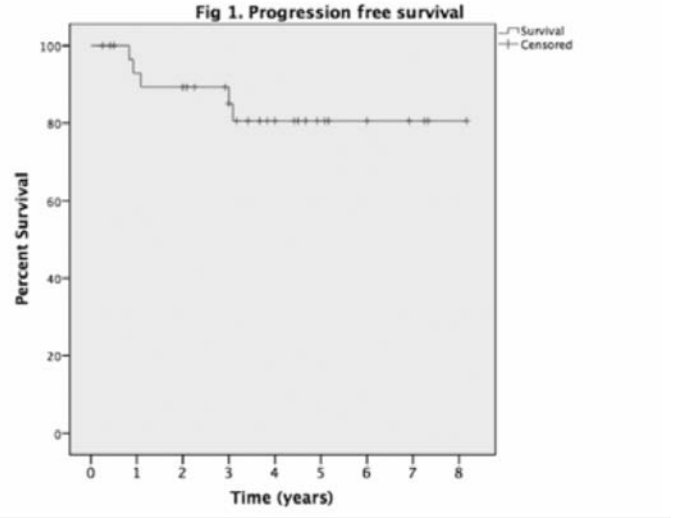

Figure 1.

Summary/Conclusions: The use of immunotherapy with rituximab or combined schedules with immunochemotherapy (R-COP and R-CHOP) followed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma patients. After ~6 years of follow-up: 63.6% (Rx4+RIT), 66.7% (R-COP+RIT) and 100% (R-CHOP+RIT) of patients continue with complete response and off of therapy.

E1135

ASSESSING RISK OVER TIME IN PATIENTS WITH SYMPTOMATIC WALDENSTRÖM MACROGLOBULINEMIA (WM). A STUDY ON 114 PATIENTS (PTS)

S. Guidez[1], J. Labreuche[2], J. Bakala[3], B. Royer[4], C. Delette[4], M. Joris[4], B. Hivert[3], H. Declercq[3], M. Verlay[3], J.P. Marolleau[4], A. duhamel[5], P. Morel[4,*]
[1]Service d'Hematologie, CHU Poitiers, Poitiers, [2]Department of Biostatistic, CHRU Lille, Lille, [3]Service d'Hematologie, CH Lens, Lens, [4]Service d'Hematologie, CHU d'Amiens, Amiens, [5]Department of Biostatistics, CHRU Lille, Lille, France

Background: By contrast, with follicular lymphoma (J Clin Oncol 2015;33:2516) or other chronic hematological malignancies (Blood 2009;114:1299; Blood 2016;128:902), few reports attempted to decipher the evolution of pts with WM, a disorder associated with delayed response to therapy in some pts.

Aims: To assess the prognostic role during the clinical course of initial international prognostic index (IPSSWM), response and progression (according to 6th International Workshop criteria).

Methods: We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1.91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively). Response rate after 1st line therapy was 70%. Sixty-two, 37 and 19 pts received a 2nd a 3rd and 4 to 6 lines of therapy respectively according to the 2nd International Workshop guidelines. Monitoring of serum monoclonal immunoglobulin concentration (SMIC) throughout the evolution of the disease was available in 106 pts. Informed consent was obtained according to the protocol submitted to the Institution Review Board

Results: Median survival after 1st line was estimated 79 months. It was estimated 69 and 65 months after 2nd line and 3rd line respectively. High IPSSWM (hIPSSWM *vs* low/intermediate) retained prognostic value for survival after 1st treatment initiation (SAFTI, p=0.0005). However, plot of hazard function showed a decrease of hazard ratio over time with a departure from the proportional hazard hypothesis (Grambsch and Therneau test: p=0.053). Consequently, Dxy concordance index obtained in multiple landmarks analyses decreased from 0.27 to 0.12, during the first 6 years of follow-up. In Cox model of SAFTI with time dependent covariate, onset of response (whatever cut-off in SMIC) had no prognostic value. By contrast, onset of progression and initiation of 2nd line therapy, retained prognostic values for SAFTI (p=0.0038 and p=0.004 respectively). Only 2 thresholds in SMIC defined a response status (observed between onset of response and progression) of prognostic value for SAFTI: namely >25% reduction in SMIC (*i.e.* minor response or better: p=0.041) and 50% (*i.e.* partial response or better: p=0.056). In similar Cox models with hIPSSWM, onset of progression (p=0.0034) and 2nd treatment initiation (p=0.0031) retained independent prognostic value beside hIPSSWM (p<=0.0026). Times elapsed from the initiation of 1st line therapy to 1st progression and to the initiation of 2nd line therapy had no prognostic value for subsequent survival. In similar Cox model of survival after 2nd line therapy with time dependent covariate no threshold in SMIC were found to be associated with a significant value of onset of response or response status. Neither onset of progression nor next treatment initiation had significant prognostic value. Similar results were observed after the 3rd line of therapy.

Summary/Conclusions: The prognostic value of initial IPSSWM decreased in part during the first 6 years of evolution. Onset of progression and 2nd treatment initiation provided additional prognostic information for predicting SAFTI. Therefore progression-free survival or time to next treatment may be satisfactory surrogate endpoint of SAFTI in WM. Further international collaborative studies are mandatory for this purpose. Assessing response in more advanced phase of the disease may require specific tools.

E1136

TIME TO NEXT TREATMENT ANALYSIS FOR EARLY AND ADVANCED STAGES OF MYCOSIS FUNGOIDES /SEZARY SYNDROME TREATED WITH BEXAROTENE AND PUVA IN COMBINATION

S. Rupoli[1,*], G. Goteri[2], G. Micucci[1], I. Federici[1], L. Canafoglia[1], P. Leoni[1], G. Brandozzi[3], F. Giantomassi[2], G. Mozzicafreddo[4], R. Alterini[5], M. Simonacci[6], L. Bugatti[7], S. Serresi[4], R. Santilli[4], A. Campanati[3], N. Pimpinelli[8]
[1]Clinica di Ematologia, [2]Istituto di Anatomia Patologica, [3]Clinica di Dermatologia, Ospedali Riuniti Umberto I- Salesi-Lancisi di Ancona, [4]Clinica di Dermatologia, I.N.R.C.A. Ancona, ancona, [5]Clinica di Ematologia, AOU Ospedale Careggi di Firenze, Firenze, [6]Clinica di Dermatologia, Ospedale di Macerata, Macerata, [7]Clinica di Dermatologia, Ospedale di Jesi, Jesi, [8]Clinica di Dermatologia, AOU Ospedale Careggi di Firenze, Firenze, Italy

Background: Bexarotene is a syntetic retinoid effective in early and advanced stages of Mycosis Fungoides (MF)/Sezary Syndrome (SS) both in monotherapy and combination schemes. Time to next treatment (TTNT) seems to be a clinically meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

Aims: We aimed to evaluate TTNT together with the usual time-to-event measures (OS and EFS) in our series of 21 refractory and/or relapsed patients with MF and SS treated with Bexarotene and PUVA in combination, that we recently published (Rupoli et al, *EJD 2016*). The follow-up of these protocols was prolonged up to February 2017.

Methods: We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We designed "mini" and "standard" protocols in which Bexarotene dose and PUVA administration were individually titrated, and tailored during induction and maintenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

Results: We enrolled 21 patients, 12 males and 9 females, with median age of 67 years (range, 30-77), of which 15 affected by early MF (13 with stage IB, 2 with stage IIA) and 7 by advanced disease (2 with stage IIB, 2 with stage IIIA, 1 with stage IIIB and 1 with stage IVA). Six patients had previously received PUVA therapy only, while fifteen patients had received other therapies.The protocol proved to be effective, well tolerated and able to induce an overall response of 85.6% at the end of induction phase (93.4% of early stage patients and 66.6% of advanced stage patients) and of 76.2% at the end of maintenance phase (86.7% of early stage patients and 14.2% of advanced stage patients). Median follow up for all patients was 85 months (6-118) with respectively 98 months (21-118) for early stages and 46 months (6-102) for advanced stages. For the entire cohort, median OS, PFS and TTNT was not reached; mean values of OS, PFS and TTNT were respectively, 90, 92 and 72 months and median EFS was 33 months. For the early stage MF cohort, the median OS, PFS and TTNT were not reached; mean values of OS, PFS and TTNT were respectively, 105, 103 and 79 months, and median EFS was 58 months. For advanced stage patients, median OS, PFS, EFS and TTNT were 32, 29, 18 and 39 months respectively.

Summary/Conclusions: Our combination treatment seems to have superior TTNT compared to data published in the literature for PUVA and bexarotene used in monotherapy. When considering early and advanced MF, 66% of our patients are estimated to be free from further treatment at 2 years, a higher percentage compared to the results of Hughes *et al.* (*Blood, 2015*) for patients treated with PUVA (54.2%) or bexarotene (36.8%) as single agents. Moreover, TTNT seems to be longer in our study than in the study by Hanel et al (*AJH* 2016) on patients treated by retinoids in monotherapy, respectively 79 *vs* 60 months (mean TTNT values) in the early stages and 39 *vs* 9 months (median TTNT values) in the advanced stages. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

E1137

PERIPHERAL BLOOD INVOLVEMENT IN PATIENTS WITH ADVANCED STAGE FOLLICULAR LYMPHOMA: CLINICAL-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT

A. Rivas-Delgado[1,*], L. Magnano[2], P. Mozas[1], I. Dlouhy [1], J. Rovira[1], A. Martinez-Trillos [1], O. Balague[3], A. Martínez[3], E. Gine[1], T. Baumann[1], J. Delgado[1], N. Villamor[2], E. Campo[3], E. Matutes[2], A. Lopez-Guillermo[1]
[1]Hematology department, [2]Hematopathology Unit, [3]Pathology department, Hospital Clinic, Barcelona, Spain

Background: Follicular lymphoma (FL) is a clinically heterogeneous indolent lymphoma. The majority of patients have a non-aggressive clinical course, but a small percentage shows a rapidly progressive disease, including histological transformation in some cases. Although disseminated disease and bone marrow infiltration are common, only a small percentage of FL patients have peripheral blood (PB) involvement. The clinical significance of the PB involvement is unclear.

Aims: To describe the clinico-biological characteristics and to determine the prognostic impact of blood involvement in patients with advanced FL.

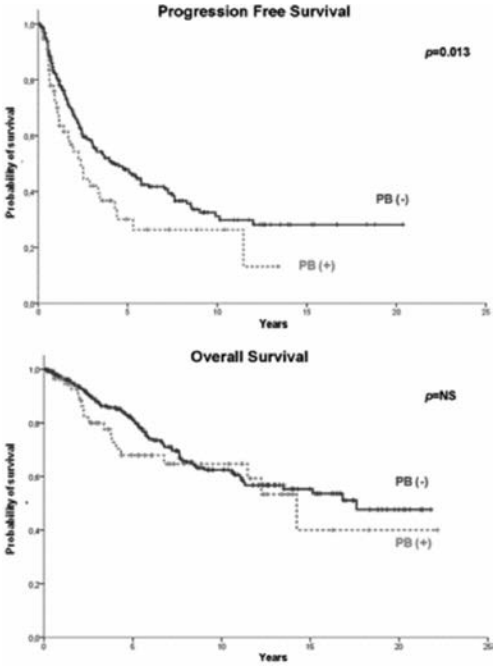

Figure 1.

Methods: We selected 304 patients in stage IV out of 654 patients diagnosed with FL between 1991 and 2014 in a single institution. Patients with a diffuse large B-cell lymphoma component, histological grade 3b and primary cutaneous FL were not included. Fifty-six (18%) had PB expression (PB+) defined by the presence of circulating FL cells by morphology, further confirmed by immunophenotype. The main clinical and biological characteristics, response to treatment and outcome were analyzed.

Results: Patients with PB+ more frequently had splenic involvement, anemia, elevated β2-microglobulin and LDH and high FLIPI score than those without PB involvement (PB-) and differences were statistically significant. There were no differences concerning the proportion of patients undergoing a watchful waiting approach (7% *vs* 9%), type of treatment, or overall response rate (83% *vs* 88%) and complete response rate. Overall, 149 patients had refractory disease or relapsed, including 34/52 (65%) PB+ and 115/225 (51%) PB-. The median follow-up was 7 years (range 0.7 - 22.2 years). The 5-year progression-free survival (PFS) of treated patients in PB+ group was 28% (95% CI: 14-42%) compared with 48% in the PB- (95% CI: 41-55%) (p=0.013). However, when the analysis was restricted to patients receiving rituximab combination regimen, 5-year PFS was 45% (95% CI: 24-66%) *vs* 64% (95% CI: 54-74%) (p=NS). Ninety-six patients died during the follow-up (19 PB+ and 77 PB-), with a 5-year overall survival (OS) of 68% (95% OR: 54-82%) in the PB+ group and of 81% (95% CI: 76-86%) in the PB- group (p= NS) (Figure). Finally, there was no difference in the risk of histological transformation or second malignancies.

Summary/Conclusions: Peripheral blood involvement in FL is associated with particular clinical features, higher tumor burden load and shorter PFS, although in the short-term it appears that has not impact on overall survival.

E1138

TREATMENT PATTERNS OF PATIENTS WITH FOLLICULAR LYMPHOMA IN A LARGE US-INSURED DATABASE FROM 2010 TO 2014

M. Mehra[1,*], N. Monga[1], B. Schenkel[2], R. Potluri[3], L. Parisi[1]
[1]Janssen Research & Development, LLC, Raritan, NJ, United States, [2]Janssen Scientific Affairs, Horsham, PA, United States, [3]SmartAnalyst Inc., New York, NY, United States, United States

Background: Follicular lymphoma (FL) is the second most common type of non-Hodgkin's lymphoma. While there are therapeutic options for patients with FL, it remains an incurable disease with conventional therapies. Furthermore, real-world treatment patterns for patients with FL are not well characterized in the literature.

Aims: To characterize the real-world treatment patterns by line of therapy (LOT) for patients with FL in a large US-insured database.

Methods: Using the Optum integrated database, patients with FL were identified and included if 1) they were diagnosed with the International Classification of Diseases, Ninth Revision (ICD-9) codes 202.0 or 202.00 to 202.08 between January 2010 and December 2014; 2) their age was ≥ 18 years at the index date (defined as date of FL diagnosis); 3) they did not have any other primary cancers during the period from 3 years prior to index date up to 1 month post-index date; and 4) they had continuous insurance coverage for 365 days prior to index date. All reporting was done using descriptive statistics.

Table 1.

Table 1. Share of regimens used in 1180 patients treated with ≥ 1 NCCN-recommended therapy.

Therapy	LOT1 (n = 1180)	LOT2 (n = 711)	LOT3 (n = 479)	LOT4+ (n = 897)	All LOTs* (n = 3267)
Rituximab monotherapy	21.3%	27.1%	30.1%	29.9%	26.2%
Bendamustine-rituximab	14.0%	10.8%	10.4%	11.4%	12.1%
Steroids	10.9%	14.2%	15.9%	9.9%	12.1%
R-CHOP	11.4%	9.7%	9.8%	10.3%	10.5%
R-CHOP-containing	4.6%	6.6%	9.4%	15.9%	8.8%
R-CVP/R-CVP-containing	3.6%	1.0%	1.0%	0.4%	1.8%
Obinutuzumab-containing	0.0%	0.1%	0.2%	0.2%	0.1%
Other rituximab-containing	12.4%	11.1%	8.6%	7.1%	10.1%
Other chemotherapies	21.8%	19.3%	14.6%	14.8%	18.3%

*Patients may receive multiple LOTs.

Results: A total of 2569 patients with FL met the inclusion criteria and were included in the analysis. In this cohort, the mean age was 60 years; 51% were male; 72% were Caucasian, 5% African American, 2% Asian, and 20% other. The median duration of follow-up was 610 days. Across all LOTs, 1180 patients (46%) had at least one National Comprehensive Cancer Network (NCCN) guideline-recommended treatment for FL, and 153 patients (6%) had steroids only in their follow-up. Across all LOTs, rituximab monotherapy (RTX) was the most frequently used regimen (26%; average duration of therapy [DOT]: 96 days), followed by rituximab-cyclophosphamide-doxorubicin-vincristine-prednisolone (R-CHOP) or R-CHOP-containing regimens (19%; average DOT: 75 days) and bendamustine-rituximab (BR) (12%; average DOT: 128 days). These regimens represented 21%, 16%, and 14% of the first LOT, and 27%, 16%, and 11% of the second LOT, respectively. Across all LOTs, the use of other FL treatments was very low, including rituximab-cyclophosphamide-vincristine-

prednisolone (R-CVP) (2%) and obinutuzumab (< 1%). Utilization trends of R-CHOP-containing regimens and RTX increased in successive LOTs, while all the other regimens remained unchanged or declined, particularly in later LOTs. RTX-containing regimens were used in 69.5% of regimens across all LOTs. The share of regimens used in different LOTs and overall are described in Table 1.
Summary/Conclusions: The use of NCCN guideline-recommended treatments in less than half of this cohort of patients with FL suggests that many patients with this form of indolent lymphoma are not adequately treated. As expected, rituximab was found to be the mainstay of treatment. Further research is needed to examine the relationship between LOT and long-term outcomes in patients with FL.

E1139

A PHASE 1 STUDY EVALUATING THE SAFETY AND PHARMACOKINETICS (PK) OF VENETOCLAX (VEN) IN JAPANESE PATIENTS (PTS) WITH NON-HODGKIN LYMPHOMA (NHL) AND MULTIPLE MYELOMA (MM)
K. Yamamoto[1,*], K. Hatake[2], N. Fukuhara[3], S. Kusumoto[4], H. Nagai[5], Y. Kobayashi[6], T. Kakihara[7], M. Shintani[7], A. Roberts[8], P. Maciag[8], S.K. Agarwal[8], A.H. Salem[8], K. J. Freise[8], T. Kiriyama[7], K. Tobinai[6]
[1]Department of Clinical Research and Department of Hematology and Cell Therapy, Aichi Cancer Center Hospital, Nagoya, Japan, [2]Department of Hematology and Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan, [3]Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, Japan, [4]Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, [5]Department of Hematology, National Hospital Organization Nagoya Medical Center, Aichi, Japan, [6]Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, [7]AbbVie GK, Tokyo, Japan, [8]AbbVie Inc., North Chicago, IL, United States

Background: The antiapoptotic protein BCL-2 is commonly overexpressed in hematologic malignancies. VEN is a potent, selective, orally bioavailable BCL-2 inhibitor that has demonstrated acceptable safety and antitumor activity in NHL and MM pts.
Aims: To evaluate the safety, PK profile, and preliminary antitumor activity of single-agent VEN in Japanese pts with NHL or MM.
Methods: Phase 1 open-label, dose-escalation study of VEN in Japanese pts with relapsed or refractory (R/R) NHL or MM (NCT02265731). Dose escalation followed a 3+3 design. After a 2-week ramp-up period with weekly dose escalation, VEN was administered daily at final doses of 300, 600, 900, or 1200mg on 21-day cycles until progression. All pts received tumor lysis syndrome (TLS) prophylaxis (allopurinol, hydration, hospitalization and monitoring) starting at least 72 hours before the first VEN dose and before each dose escalation. Adverse events (AEs) were assessed by NCI CTCAE v4.0. Dose-limiting toxicities (DLTs) were determined during the ramp-up period and during cycle 1. Responses were assessed by 2007 IWG (NHL) or 2006 IMWG (MM) criteria. Informed consent was obtained from all pts.
Results: As of January 19, 2017, 20 pts (50% male; median age 65 years [39–81]) have been enrolled: 3 pts in the 300-mg, 7 pts in the 600-mg, 7 pts in the 900-mg, and 3 pts in the 1200-mg VEN dose cohorts. Eighteen (90%) pts had NHL (stage III/IV, n=14), including 11 with follicular lymphoma (FL), 6 with diffuse large B-cell lymphoma (DLBCL), and 1 with concurrent FL+DLBCL; 2 (10%) pts had MM at diagnosis. Treatment-emergent AEs (all grades) in >20% pts were lymphopenia (80%), neutropenia (60%), leukopenia (50%), and anemia (25%), and non-hematologic toxicities including nausea (55%), vomiting, diarrhea, and nasopharyngitis (30% each). Grade ≥3 treatment-related AEs were lymphopenia (45%), neutropenia (40%), and leukopenia (30%). One pt in the 600-mg dose cohort experienced grade 3 pemphigus as DLT after receiving 2 doses of 100-mg VEN on day 2 of the dose ramp-up period. One DLBCL pt died while on study due to disease progression. No TLS events were reported. Steady-state VEN exposures were nearly dose proportional across 300-mg to 900-mg doses. At the 1200-mg dose, exposures to VEN increased less than dose proportionally, which is consistent with non-Japanese subjects. VEN exposures were comparable between Japanese and non-Japanese pts at the 300-mg dose. At higher doses, individual exposures were generally within the range observed in non-Japanese pts but mean exposures were 30–100% higher. OR was seen in 8/19 (42%) pts evaluable for efficacy. Among pts with NHL, 8/17 (47%) had an OR (CR+PR), including 2 (12%) CR (both pts with FL) and 6 (35%) PR; 6/17 (35%) pts had SD and 3/17 (18%) pts progressed while on treatment. The 2 (100%) pts with MM (1 with t[11;14]) had PD. Time on study for all pts ranged from 2 to 795 days; at data cutoff, 7/20 (35%) pts were still on study, with treatment duration ranging from 98 to 795 days.
Summary/Conclusions: VEN monotherapy has a tolerable safety profile in Japanese pts with R/R NHL or MM, with most common toxicities being hematologic. Individual exposures were generally within the range observed in non-Japanese pts but mean exposures were 30–100% higher. Overall, the OR rate was high, with nearly half the pts with NHL achieving an OR. Further evaluation of VEN in Japanese pts with hematologic malignancies is ongoing.

E1140

A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY BY FLOW CYTOMETRY
M. Sartor[1,*], E. Lau[1], V. Luu[1], Z. Timbol[1], S. Wong[1], S. Deo[1], L. Pasalic[1], D. Brown[2], E. Tegg[1], D. Gottlieb[3]
[1]Haematology, [2]immunopathology, Weatmead Hospital, [3]faculty of medicine, Sydney University, Sydney, Australia

Background: T-cell lymphoprolferative disorders are amongst the most challenging diagnoses in haematology. Flow cytometric T-cell receptor (TCR)-V(β) repertoire analysis (TCR-V(β)-R) is a sensitive method for detection of T-cell clonality; however, the assay is cumbersome owing to the required eight-part analyses that limit its clinical utility.
Aims: Here we describe a simplified flow cytometric method utilising a monoclonal antibody Jovi-1 that targets the T-cell receptor β constant domain 1 (TRBC1). The α/β TCR is a pan T-cell antigen, expressed on >90% of T-cell lymphomas and all normal T-cells. A feature of the TCR is that the β-constant region comprises 2 functionally identical genes: TRBC1 and TRBC2. Each T-cell expresses only one of these. Consequently, normal T-cells will be a mixture of individual cells expressing either TRBC1 or 2, while a clonal T-cell disorders will exclusively express TRBC1 or 2.
Methods: Using multiparameter flow cytometry we assessed the expression of Jovi-1 in normal donors (n=19), T-cell leukaemia cell line (n=1), T-LGL (n=9), T-NHL (n=3), Sezary syndrome (n=3) and patients with reactive lymphocytosis (n=20). A comparison of Jovi-1 and TCR-V(β)-R was also performed to compare the two approaches.
Results: Jovi-1expression within the CD4 and CD8 compartments of T-cells in normal donors was a median of 42.6% (range 33.7%> 49%) and 36.4% (range 22.3%> 48.5%) respectively. The T-cell line, Jurkat was exclusively positive for Jovi-1. Of the 9 patients with T-LGL, 7 patients shared a common T-cell phenotype CD3+/CD8+/CD4-, one patient was predominantly CD4+ and the other patient was dual negative for CD4 and CD8. Jovi-1 expression within the abnormal T-cell population of this group of patients was >90% restricted to one compartment; these findings were confirmed by TCR-V(β)-R analysis. Similar results were also obtained in each case of T-NHL and Sezary syndrome, more than 90% of T-cells from the population with an abnormal phenotype (CD3dim/CD4+/CD8-, CD3+/CD4+/CD8+, CD3+/CD4+/CD8- and CD3+/CD4+/CD7- respectively) were either positive or negative for Jovi-1. Patients with persistent lymphocytosis were also assessed for Jovi-1 expression. Within this group all patients had Jovi-1 positive and negative compartments within CD4 and CD8 T-cells.
Summary/Conclusions: In summary we have demonstrated a novel approach in the assessment of T cell clonality by targeting T-cell receptor β constant domain 1 (TRBC1). The addition of Jovi-1 in routine practice could improve the clinical evaluation of abnormal T-cell populations by flow cytometry.

E1141

A HIGHER AMOUNT OF LILOTOMAB PRE-DOSING INCREASES THE ACTIVITY-ADJUSTED AUC AND HAS A PROTECTIVE EFFECT AGAINST MYELOSUPPRESSION OF LUTETIUM (177LU)-LILOTOMAB SATETRAXETAN IN INDOLENT NHL PATIENTS
A. Kolstad[1,*], U. Madsbu[1], C. Stokke[2], J. Blakkisrud[2], A. Muftuler Løndalen[1], J. Dahle[3], L. Baylor Curtis[3], Å. Østengen[3], K. Brustad Melhus[3], S. Turner[3], M. Erlanson[4], T. Illidge[5], H. Holte[1]
[1]Radiumhospitalet, [2]Oslo University Hospital, [3]Nordic Nanovector, Oslo, Norway, [4]Norrland University Hospital, Umea, Sweden, [5]University of Manchester, Manchester, United Kingdom

Background: lutetium (^{177}Lu)-lilotomab satetraxetan (Betalutin®) is a novel CD37-binding murine IgG_1 antibody radionuclide conjugate (ARC), in a ready-to-use formulation currently in Phase 1/2 clinical development for the treatment of indolent non-Hodgkin lymphoma (iNHL). Previously, pharmacokinetic (PK) data have been reported from 2 treatment arms of the ongoing LYMRIT-37-01 study. In this abstract PK data from 4 treatment arms are presented for the first time.
Aims: This PK sub-study in iNHL patients (pts) was designed to determine the PK profile of ^{177}Lu-lilotomab when administered after four different pre-dosing schedules.
Methods: Patients with relapsed incurable indolent NHL, with platelet counts ≥150 x10^9/L and <25% bone marrow involvement were eligible for inclusion in the study. All pts received either one or two doses of rituximab to deplete normal B cells. In addition, prior to ^{177}Lu-lilotomab administration pts also received:
- 40mg lilotomab prior to 10, 15 or 20 MBq/kg ^{177}Lu-lilotomab;
- no pre-dosing prior to 10 or 15 MBq/kg ^{177}Lu-lilotomab;
- 250 or 375mg/m^2 rituximab prior to 15 MBq/kg ^{177}Lu-lilotomab;
- 100mg/m^2 lilotomab prior to 15 or 20 MBq/kg ^{177}Lu-lilotomab.

PK samples were collected at 0 and 5 minutes, then after 1, 2, and 20 hours and at 2, 3, 4, 7, 14 and 21 days post-^{177}Lu-lilotomab administration. The patients were followed with weekly blood counts for 12 weeks post-treatment.
Results: A total of 22 pts were enrolled into this PK sub-study, 19 with follicular lymphoma, 2 with mantle cell and 1 with marginal zone histologies. The number

of prior therapies ranged from 1 to 7, median body weight was 79 kg (range: 58-118kg).The administered activity across all treatment groups ranged from 746 to 1982 MBq. The table below shows a summary of the median PK and haematology safety results for ^{177}Lu-lilotomab by treatment group. The activity-adjusted $AUC_{0-\infty}$ of ^{177}Lu-lilotomab increased with 100mg/m^2 of lilotomab compared to the other pre-dosing regimens ($p<0.001$ compared to 40mg lilotomab). The median volume of distribution and clearance were both reduced with 100mg/m^2 of lilotomab compared with the other pre-dosing regimens. However, activity adjusted Cmax was similar. Smaller percentage post-treatment reductions in platelet and neutrophil counts were observed in patients receiving 100mg/m^2 lilotomab. Most common grade 3/4 AEs were hematological and were transient and reversible.

Table 1.

Median/Pre-dose regimen	40 mg lilotomab N=9	No-predosing N=3	Rituximab N=4	100 mg/m^2 lilotomab N=6
Activity adjusted $AUC_{0-\infty}$(h*kBq/mL)/MBq	8.91	4.34	6.08	13.07
Activity adjusted Cmax (kBq/mL)/MBq	0.21	0.18	0.24	0.22
Vz L	10.5	17.8	12.5	5.3
Cl mL/h	126	230	167	77
% platelet count reduction #	82	94	88	39
% neutrophil count reduction#	64	94	86	58

#15 MBq/kg only. N=3 for each arm except with no pre-dosing n=2

Summary/Conclusions: A higher pre-dose of lilotomab increases the activity-adjusted AUC and decreases the volume of distribution and clearance rate of ^{177}Lu-lilotomab in iNHL pts. Despite the increase in AUC the percentage reductions in neutrophil and platelet counts were smaller, indicating that a higher dose of lilotomab may have a protective effect against the myelosuppression associated with ^{177}Lu-lilotomab. Further characterisation of 20 MBq/kg dose of ^{177}Lu-lilotomab with 100mg/m^2 of lilotomab pre-dosing is ongoing and will be presented.

E1142

PHARMACOKINETICS AND TOLERABILITY OF OFATUMUMAB AND BENDAMUSTINE IN PATIENTS WITH INDOLENT B-CELL NON-HODGKIN'S LYMPHOMA

A. Forero-Torres[1,*], J.C. Chandler[2], S.P. Iyer[3], A.S. Kanate[4], M. Quinlan[5], P. Hoever[6], M. Izquierdo[6], V. Duval[6], S. Madan[7]
[1]Division of Hematology / Clinical Oncology, University of Alabama at Birmingham, Alabama, [2]West Cancer Center, Tennessee, [3]Houston Methodist Cancer Center, Houston, [4]West Virginia University, Morgantown, [5]Novartis Oncology, East Hanover, NJ, United States, [6]Novartis Pharma AG, Basel, Switzerland, [7]Cancer Therapy & Research Center, San Antonio, United States

Background: Anti-CD20 antibody rituximab (R)-based immunochemotherapy is the standard treatment for untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL). Due to the inevitable relapse of patients with iNHL, an unmet need remains for active and well-tolerated novel therapies. Bendamustine (BEN) is approved for the treatment of refractory iNHL, and the combination therapy BEN-R showed efficacy in the treatment of relapsed iNHL. Ofatumumab (OFA) is an anti-CD20 human monoclonal antibody (mAb) with high binding affinity and slower dissociation from a distinct membrane-proximal epitope on both small and large loops of CD20. OFA is indicated for the treatment of chronic lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in patients with iNHL and therefore the potential for drug-drug interaction was investigated.
Aims: The study aimed to evaluate the pharmacokinetics (PK) of OFA and BEN alone and in combination, along with the safety and tolerability assessments in patients with previously untreated or relapsed iNHL.
Methods: In this Phase I open-label, multicentre study, patients (aged ≥18 years) with previously untreated or relapsed iNHL were randomized 1:1 to Arm A (OFA + BEN) or Arm B (OFA alone) to receive at least four cycles and up to eight cycles of treatment (cycle length 28 days). All patients provided informed consent. Arm A patients received single-sequence treatment of BEN, then OFA + BEN, BEN (90mg/m^2) on days 1 and 2 every 28 days for up to 8 cycles, and OFA (1000mg) on day 1 of weeks 2, 3, and 4 of cycle 1 and on day 1 of cycles 2-8. Patients in Arm B received OFA alone at same dosing schedule. Blood samples including all end-of-infusion (EOI) PK samples were collected for plasma concentration over time. The primary PK parameters C_{max}, AUC_{last}, AUC_{inf} were derived using non-compartmental analysis. All adverse events (AEs) and severe AEs (SAEs) were recorded for safety assessments.
Results: Thirty two patients were randomized (15 in Arm A and 17 in Arm B), 3 patients in Arm A discontinued study treatment due to consent withdrawal (2 patients) and infusion related AE (1 patient). All 32 patients were included for safety and PK concentration analysis while 30 patients (15 in each arm) were included for PK parameters. Patient and disease characteristics were similar between treatment arms; the majority of patients from both arms did not receive prior NHL therapy. PK concentration profiles and PK parameters of OFA were comparable when administered alone or co-administered with BEN (Table 1). As compared to OFA alone, there was a decrease of 14% in C_{max} and 15% in AUC_{last} when OFA was co-administered with BEN, which was not considered relevant (Table 1). BEN PK concentration profiles and PK parameters were comparable with or without OFA co-administration (Table 1).
All patients reported AEs. The most frequent treatment-related AEs were infusion related reaction in 53% and 47%, nausea in 33% and 35%, fatigue in 33% and 18% patients in Arm A and Arm B, respectively. The percentages of patients with grade 3/4 AEs were higher in Arm A (53%) compared to Arm B (24%). Cytopenias were present in 40% of patients in Arm A and 6% in Arm B. Four SAEs were related to study treatment in Arm A while none in Arm B.

Table 1.

Table 1. Primary PK parameters and Statistical Analysis of the primary PK parameters for OFA and BEN

	Geometric mean (95% CI)		%CV$_b$		Median (Min-Max)		Geometric Least Square Mean		
OFA – PK parameter population	OFA + BEN	OFA alone	OFA + BEN	OFA alone	OFA + BEN	OFA alone	OFA + BEN	OFA alone	Ratio (90% CI)
*AUC_{inf} (hr*µg/mL)	56100 (.)	65400 (8490-504000)	-	23.0	56100 (56100-56100)	66300 (55700-76800)	56100	65400	0.857 (0.148-4.97)
AUC_{last} (hr*µg/mL)	91700 (77400-109000)	108000 (84500-138000)	28.7	46.4	94500 (47500-131000)	126000 (50300-204000)	91700	108000	0.850 (0.666-1.08)
C_{max} (µg/mL)	383 (341-429)	443 (380-515)	19.2	28.0	363 (276-517)	481 (275-606)	383	443	0.864 (0.741-1.01)
BEN – PK parameter population	OFA + BEN	BEN alone	OFA + BEN	BEN alone	OFA + BEN	BEN alone	OFA + BEN	BEN alone	Ratio
AUC_{inf} (hr*µg/L)	6740 (5540-8210)	6880 (5390-8770)	35.2	44.0	6610 (3580-13900)	6320 (4120-14100)	6720	6780	0.991 (0.842-1.17)
AUC_{last} (hr*µg/L)	6740 (5540-8210)	6880 (5390-8770)	35.2	44.0	6610 (3580-13900)	6320 (4120-14100)	6720	6780	0.991 (0.842-1.17)
C_{max} (µg/L)	5880 (4640-7440)	6060 (4910-7500)	42.6	38.0	5440 (3250-11600)	58600 (3430-11700)	5880	6020	0.977 (0.797-1.20)

* No conclusion could be drawn with respect to AUC_{inf} due to very limited sample size (n=2 in OFA alone arm and n=1 in OFA + BEN arm); %CV$_b$, Between-subject coefficient of variation CV$_b$ (%)

Summary/Conclusions: No relevant drug-drug interaction between OFA and BEN was observed in this study. OFA alone or in combination with BEN exhibited manageable safety profile in patients with iNHL.

Infectious diseases, supportive care

ASSESSMENT OF INTERNATIONAL CONSENSUS GROUP FOR HEMATOLOGY (ICGH) SMEAR REVIEW RULES FOR AUTOMATED PLATFORMS IN THE DETECTION OF MALARIA

J. Vaughan[1,2,*], E. Benade[1,2], S. Havyarimana[1,2], N. Alli[1,2]
[1]Haematology, National Health Laboratory Services, [2]Molecular Medicine and Haematology, University of the Witwatersrand, Johannesburg, South Africa

Background: Peripheral blood smear review (SR) is a useful adjunct to the full blood count (FBC) and differential white cell count (DWCC), but is labor intensive and time consuming. For this reason, the international consensus group for hematology (ICGH) published guidelines to reduce SR rates in clinical laboratories using rules based on a combination of blood parameters and instrument suspect flags. These rules have reduced SR rates in many laboratories, but adjustment is often required to accommodate for local pathology/clinician preferences. As malaria is common in Johannesburg (JHB) (although not endemic), this study was undertaken to retrospectively evaluate the performance of modified ICGH SR rules for detection of malaria at the Chris Hani Baragwanath Academic Hospital Laboratory (CHBAH) (part of the National Health Laboratory Service (NHLS) network) in JHB, South Africa.
Aims: To assess the performance of the CHBAH NHLS SR rules in the detection of malaria.
Methods: Malaria test results (*P. falciparum* antigen & thick/thin SR) were extracted from the laboratory information system and corresponding FBCs assessed in those with parasitemia. All ICGH rules were applied to patients with both a FBC and DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Resarch Ethics Committee of the University of the Witwatersrand.
Results: Of the 153 samples included, all had *P. falciparum* parasitemia and 37 were collected from patients with severe malaria. A FBC with a DWCC was performed in 72/153(47.1%) patients, and a FBC alone in 81/153(52.9%). SR rules were triggered in 132(86.3%) patients (68(84.0%) in those with only a FBC performed and 64(88.9%) in those with a FBC and DWCC). The thrombocytopenia (platelets (Plt) <100x10^9/l) and anemia (Hb <7g/dl) rules were the most common, triggering in 105(79.5%) and 24(15.7%) patients respectively. Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/more of these triggered in the absence of parameter flags in only 5(7.9%) patients with a DWCC requested. There were 21(13.7%) unflagged (false negative (FN)) samples, of which 20(95.2%) had a Hb level ≥10g/dl, 14(70.0%) had both a Hb ≥10g/dl and a plt count >120x10^9/l and 8(38.1%) had a Hb ≥10g/dl and a plt count >150x10^9/l. On SR, malaria parasites were missed in a further 13.0% of cases, predominantly when the parasitemia was low (median 0.35% in those missed *vs* 3.1% in those with parasites identified). Reassuringly, SR rules were triggered in all the patients with severe malaria, and the parasites identified in 90.5% of these.
Summary/Conclusions: ICGH SR rules are FN in 13.7% of patients with malaria, largely in those with near-normal blood counts. Furthermore, SR failed to identify the parasites in a further 13.0% of cases (particularly those with very low parasitemia). Elimination of a proportion of FN samples is thus not likely to be possible, and clinical vigilance for this condition is required. Reassuringly, SR rules were flagged in all patients with severe malaria, thus increasing the likelihood of this entity being diagnosed if not tested for specifically.

A PROSPECTIVE MULTICENTER STUDY OF CANDIDEMIA IN NEUTROPENIC PATIENTS WITH HEMATOLOGICAL DISEASES: INCIDENCE, RISK FACTOR AND OUTCOMES

C.H. Yan[1,*], D.-P. Wu[2], J.-D. Hu[3], H. Huang[4], M. Jiang[5], J. Li[6], M. Hou[7], C. Wang[8], Z. Shao[9], T. Liu[10], Y. Hu[11], X.-J. Huang[1]
[1]Peking University People's Hospital, Beijing, [2]The First Affiliated Hospital of Soochow University, Suzhou, [3]Fujian Medical University Union Hospital, Fuzhou, [4]The First Affiliated Hospital of Medical School of Zhejiang University, Zhejiang, [5]he First Affiliated Hospital Of Xinjiang Medical University, Wulumuqi, [6]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, [7]Qilu Hospital of Shandong University, Jinan, [8]Shanghai General Hospital, Shanghai, [9]Tianjin Medical University General Hospital, Tianjin, [10]West China Hospital of Sichuan University, Chengdu, [11]Wuhan Union Hospital, Wuhan, China

Background: Candidemia is one of the most common nosocomial bloodstream infections and is associated with high morbidity and mortality, especially amongst the immunocompromised population. Several articles focus on the epidemiology of candidemia, but most of them were from cancer patients, patients with hematological malignancies, patients receiving solid organ transplant, or patients receiving hematopoietic stem cell transplantation (HSCT). Only 3 retrospective studies from single center described the clinical and microbiological features of candidemia in neutropenic patients with hematological malignancies.
Aims: A prospective, multicenter, observational study was designed to investigate the incidence, risk factors and outcomes of candidemia in neutropenic patients with hematological diseases.
Methods: This study was conducted in 11 hematological centers in China over a five-month period. From October 20, 2014 to March 20, 2015, consecutive patients of any age were included in this prospective study if they met the following criteria: (1) had hematological disease; (2) experienced at least one episodes of neutropenia during hospitalization.
Results: A total of 1139 concecutive cases were enrolled in this study. Out of 1139 neutropenic cases, 8 developed candidemia. The median time from neutropenia to diagnosis of candidemia was 18 days (range: 9-20 days). Among the 8 causative strains, 5 were *C. albicans* and other 3 were C. *Tropicalis*. The cumulative incidence of candidemia in neutropenic patients with hematological diseases was 0.00% [95% confidence interval (CI): 0.00, 0.00%] at 7 days, 0.26% (0.00, 0.65%) at 14 days, 2.24% (0.67, 3.81%) at 21 days and 2.24% (0.67, 3.81%) at 28 days after neutropenia, respectively. Among 8 casese with candidemia, 3 were from patients receiving HSCT, other 8 were from patients who had acute myeloid leukemia (AML) and receiving induction chemotherapy. The cumulative incidence of candidemia in patients with AML and receiving induction chemotherapy was also significantly higehr than that in patients receiving HSCT and other patients (5.45% *vs.* 3.1%9 *vs.* 0.00%, *P*=0.023). In addition, multivariate analysis suggested that gastrointestinal mucositis (OR=26.038; *P*=0.003), central venous catheterization (OR=12.904, *P*=0.027), duration of neutropenia >17 days (OR=11.649, *P*=.028) and diabetes (OR=12.435, *P*=0.037) were the risk factors of candidemia in neutropenic patients with hematological diseases. Based on the risk factors, 1139 cases were stratified into low-risk group (0-2 risk factors), intermediate-risk group (3 risk factors), and high-risk group (4 risk factors). The cumulative incidence of candidemia was higher in high-risk group than that in intermediate-risk group and low-risk group (100.00% *vs.* 25.84% *vs.* 0.27%, *P*<0.0001). Besides, the antifungal agents used when candidemia developed were itraconazole (3 cases), voriconazole (2 cases), caspofungin (2 cases), and amphotericin B (1 case). All patients were treated effectively and no one died of candidemia.
Summary/Conclusions: This study provided a description for the epidemiological study of candidemia in neutropenic patients with hemotological diseases. This study defined the risk factors associated with candidemia in these patients, and confirmed that based on the risk factors, risk-stratification could identify the patients with a high-risk of candidemia.

E1145

BRONCHOALVEOLAR LAVAGE AS SYSTEMATIC APPROACH FOR EARLY DIAGNOSIS OF LUNG INFILTRATES AND INVASIVE PULMONARY ASPERGILLOSIS IN HEMATOLOGIC PATIENTS: A PROSPECTIVE SINGLE INSTITUTION STUDY

F. Marchesi[1,*], A. Spadea[1], F. Pimpinelli[2], G. Prignano[2], M.G. Paglia[3], D. Forcella[4], S. Gumenyuk[1], D. Renzi[1], F. Palombi[1], A. Vulcano[3], F. Pisani[1], A. Romano[1], E. Papa[1], F. Facciolo[4], F. Ensoli[2], C. Girmenia[5], A. Mengarelli[1]
[1]Hematology and Stem Cell Transplant, Regina Elena National Cancer Institute, [2]Molecular Virology, Pathology and Microbiology Laboratory, San Gallicano Dermatological Institute, [3]Microbiology and Infectious Diseases Biorepository Laboratory, National Institute of Infectious Diseases "L. Spallanzani", [4]Thoracic Surgery Unit, Regina Elena National Cancer Institute, [5]Hematology Unit, Sapienza" University, Rome, Italy

Background: The best diagnostic approach of lung infiltrates (LI) remains to be established. Despite bronchoscopy with bronchoalveolar lavage (BAL) appears to be useful for LI diagnosis, hematologists and thoracic surgeons often have qualms in performing bronchoscopy in this difficult patient population at high-risk of procedure-related complications. A proper diagnostic approach at LI seems to be particularly relevant in neutropenic patients and/or in patients with an unfavorable clinical response to broad-spectrum antibiotics, in which the cause of LI are often filamentous fungi, as *Aspergillus* spp.To date, there is not a general consensus regarding the diagnostic panel to apply in hematologic patients undergoing bronchoscopy for LI.
Aims: To evaluate the feasibility of bronchoscopy with BAL as systematic diagnostic approach at LI in hematologic patients, focusing on its role to diagnose invasive pulmonary aspergillosis (IPA).
Methods: Bronchoscopy was performed in all hospitalized patient with diagnosis of acute leukemia and LI at onset of disease before therapy start, and in any other hematologic patient in any phase of disease with LI requiring hospitalization because of concomitant febrile neutropenia and/or respiratory distress not responding to broad-spectrum antibiotics. Criteria for not response to broad-spectrum antibiotics were defined as persistent (> 48 h) fever and/or persistent respiratory distress. In all cases we performed the same diagnostic work-up including blood-swabs cultures, serum galactomannan (GM) assessment (in three consecutive checks), serum beta-D-glucan, serum PCR for CMV; BAL

fluid was studied by bacterial and fungal cultures, GM and PCR for *Streptococcus pneumoniae*, *Legionella pneumophila*, *Chlamidophila pneumoniae*, *Mycoplasma pneumoniae*, *Bordetella pertussis*, *Bordetella parapertussis*, *Haemophilus influenziae*, respiratory virus including CMV, *Pneumocystis jiroveci*, *Mycobacterium tuberculosis* complex*, Nocardia spp.*, *Lysteria monocitogenes and Aspergillus spp*. Available commercial kits were used according to manufacturer's instructions.
Results: Out of 769 patients consecutively admitted in our ward, 85 had LI and 47 of them underwent BAL (total amount: 51 procedures). A causal agent of LI was detected in 33 cases (65%) allowing to modify the ongoing anti-microbial treatment in 25 of these ones (76%). Twelve cases of probable IPA, according to standard criteria, were diagnosed. Seven cases of LI fulfilling the radiologic criteria for IPA, though presenting only a positive *Aspergillus* PCR on BAL, were detected and treated as probable IPA. One life-threatening post-procedure complication was observed.
Summary/Conclusions: BAL seems a safe approach for an early diagnosis of LI in hematologic patients. The assessment of a broad diagnostic panel allowed the detection of a putative agent in 65% of cases. Assessment of *Aspergillus* by PCR on BAL proved useful for probable IPA diagnosis.

E1146

ESCAPE DRUG-RESISTANT INFECTIONS IN HEMATOLOGICAL MALIGNANCIES. DARE TO REVIEW!

C. Gentille Sanchez[1,*], K. Sun[1], P. Teegavarapu[1], Q. Qian[1], P. Mamta[2], S. Wong[2], I. Ibrahim[1], L. Rice[3], S.R. Pingali[1], S. Iyer[1]
[1]Houston Methodist Cancer Center, [2]Houston Methodist Research Institute, [3]Houston Methodist Department of Hematology, Houston Methodist Hospital, HOUSTON, United States

Background: Patients with hematological cancers are at a high risk for increasingly resistant and severe infections. The Infectious Diseases Society of America has defined commonly resistant bacteria as ESKAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteriaceae organisms (E. coli, Proteus) can be added to this group and change the acronym from ESKAPE to ESCAPE.
Aims: We performed a retrospective review of the rate of ESCAPE infections, resistance profile, and outcomes in patients with various hematological malignancies at the Houston Methodist Hospital from 2006 to 2015.
Methods: The patient data was obtained from METEOR (Methodist Environment for Translational Enhancement and Outcomes Research), a clinical data warehouse that contains records dating back to January 1, 2006, with over 3 million patients and over 10 million unique patient encounters. We queried for leukemia (AML, CML, ALL, CLL), amyloidosis and myelodysplastic syndrome (MDS) along with hospitalizations due to bacterial infections. Baseline demographics and overall outcomes were also obtained.

Table 1.

Culture Results[1]	ALL	AML	CLL	CML	AMYLOIDOSIS	MDS	Unspecified	Total
Enterobacter	4	10	15	0	20	21	1	71 (4.5%)
Staphylococcus aureus	4	79	37	14	36	116	6	292 (18.5%)
Klebsiella	5	59	21	7	23	90	0	205 (12.3%)
Acinetobacter	0	14	3	0	12	12	0	41 (2.6%)
Pseudomonas	8	51	42	12	50	104	0	267 (16.9%)
Enterococcus	13	115	39	18	44	138	4	371 (23.4%)
Escherichia coli	8	34	26	14	20	100	7	209 (13.2%)
Proteus	2	17	22	4	2	38	1	86 (5.4%)
Clostridium difficile[2]	2	21	5	1	4	8	0	41 (2.6%)
Total	46 (2.9%)	400 (25.3%)	210 (13.3%)	70 (4.4%)	211 (13.3%)	627 (39.6%)	19 (1.2%)	

1. Cultures included blood cultures, urine cultures, respiratory secretion cultures and tissue cultures
2. Results obtained from positive PCR tests for clostridium difficile toxin A and toxin B

Results: Out of 6017 patients with Hematological Malignancies, 660 patients with 684 malignant diagnoses were found; 235 had MDS, 174 had AML, 105 had CLL, 77 had amyloidosis, 44 had CML, 39 had ALL, and 10 had an unspecified hematological cancer. Of 1132 infectious events, 62% were ESCAPE infections. The bacteria most frequently isolated were Enterococcus (23.4%), Staphylococcus aureus (18.5%) and Pseudomonas (16.9%). Bacteremia was the most predominant type of infection (41.9%) followed up by urinary tract infections (38.2%). Patients with MDS (39.6%) and AML (25.3%) were mainly affected. A prevalent resistance to levofloxacin was detected in gram positives and gram-negative organisms (29-54%). Pseudomonas, E. coli, Proteus and Klebsiella pneumoniae showed a significant resistance to broad-spectrum antibiotics including aztreonam (23-34%), cefepime (7-23%), and imipenem (22%). Proteus had the highest mortality rate (45.2%), followed by Enterococcus (44.2%), and Pseudomonas (36.7%).
Summary/Conclusions: Hematological cancers with risk for neutropenia such as MDS and AML were the most affected by ESCAPE. Bacteremia was frequently seen. Gram-negative pathogens had an increased resistance to broad-spectrum antibiotics and higher mortality rates. A significant resistance to levofloxacin, a prophylactic antibiotic, was also noted. New strategies for reducing ESCAPE in MDS and AML are required. Further statistical review of this data set will be presented at the EHA Meeting, Madrid 2017.

E1147

PROPOSED PEGIFLGRASTIM BIOSIMILAR CHS-1701 DEMONSTRATES PHARMACOKINETIC AND PHARMACODYNAMIC SIMILARITY TO MARKETED PEGFILGRASTIM IN A RAT NEUTROPENIA MODEL AND IN HEALTHY SUBJECTS

P. O'Connor[1,*], H. Tang[1], F. Civoli[1], B. Finck[1], V. Vexler[1]
[1]Coherus BioSciences, Inc., Redwood City, United States

Background: CHS-1701, a proposed biosimilar of pegfilgrastim, is being developed to decrease infection in patients receiving myelosuppressive anticancer drugs associated with febrile neutropenia**.**
Aims: The aim of the preclinical study was to compare pharmacokinetic (PK) and pharmacodynamic (PD) effects of CHS 1701 and marketed pegfilgrastim (MP) in a rat model of cyclophosphamide (CPA)-induced neutropenia. Since pegfilgrastim has the same mechanism of action in humans and rats, preclinical models of CPA-induced neutropenia are considered to be pharmacologically and clinically relevant models of chemotherapy-induced neutropenia in cancer patients. The aim of the clinical program was to demonstrate the PK and PD bioequivalence of CHS-1701 to MP in a multi-center, randomized, single-blind, 3-sequence, 3-period, crossover study in healthy subjects.
Methods: In the rat model, a single SC dose of CHS-1701 or MP was administered at 24 hours after CPA administration, when the peripheral neutrophil counts had been reduced by ~60-70% from baseline. Doses from 30 to 1000 µg/kg were evaluated in order to provide a broad range of exposures to pegfilgrastim and allow for the comparison of CHS-1701 and MP dose response in a steep part of the PD dose response curve. The PD response was evaluated in the blood by analyzing time-dependent changes in absolute neutrophil counts (ANC) and calculating ANC $AUC_{0\text{-last}}$ and in the bone marrow by analyzing pegfilgrastim-induced expansion of myeloid cells and calculating the myeloid to erythroid cell (M:E) ratio. In the clinical PK/PD study, healthy subjects (n=122) were randomized to 1 of 3 treatment sequences; each included 1 therapeutic dose of CHS-1701 (6-mg) and 2 doses of MP (6-mg) separated by ≥28 days. Bioequivalence of CHS-1701 to pegfilgrastim was demonstrated for PK (C_{max}, $AUC_{0\text{-}\infty}$) if the 90% confidence interval (CI) for the geometric mean ratio (GMR) was within 80-125% and for PD (ANC_{max} and ANC $AUC_{0\text{-last}}$) if the 90% CI for the GMR was within 80-125%.
Results: In the rat model, CHS-1701 and MP demonstrated similar time- and dose-dependent changes in the number of peripheral neutrophils and in the proliferative response in the bone marrow. No differences between CHS-1701 and MP in PD (Fig. 1) or PK were observed across the tested dose range.
In the clinical study, PK bioequivalence criteria were met for C_{max} (GMR=105.0; 90% CI 95.5, 115.4) and $AUC_{0\text{-}\infty}$ (GMR=97.5; 90% CI 88.6, 107.2). Pre-specified PD bioequivalence criteria (90% CI) and more stringent criteria (95% CI) were met for ANC_{max} (GMR=99.6; 90% CI: 96.2, 103.2; 95% CI: 95.5, 103.9) and ANC $AUC_{0\text{-last}}$ (GMR=96.7; 90% CI: 92.2, 101.4; 95% CI: 91.4, 102.4). The two treatments displayed similar safety profiles. Investigator-designated treatment-related AEs occurred in 71.9%, 71.2%, and 62.8% of subjects during the CHS-1701, first MP, and second MP dosing periods, respectively, and most commonly included back pain (46.9%, 42.3%, 30.8%), headache (29.2%, 36.9%, 29.5%), and arthralgia (8.3%, 13.5%, 7.7%). There were no treatment-related serious AEs.

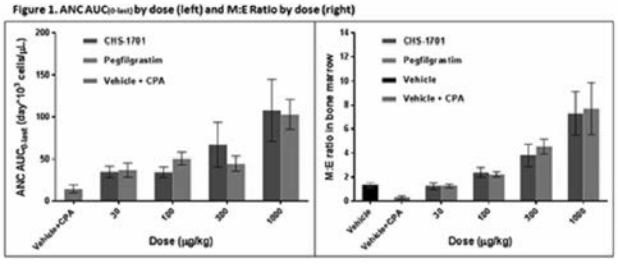

Figure 1.

Summary/Conclusions: The dose-dependent changes in the neutropenia model were consistent with the PD effects of pegfilgrastim in humans and demonstrate that CHS-1701 results in comparable neutrophil recovery and time course compared to marketed pegfilgrastim. The clinical study demonstrates highly similar PK, PD, and safety profiles in humans for CHS-1701 and marketed pegfilgrastim. Overall, preclinical and clinical results suggest that CHS-1701 would provide similar PK, PD, safety, and efficacy to marketed pegfilgrastim in patients with chemotherapy-induced neutropenia.

E1148

A RETROSPECTIVE REVIEW IDENTIFYING RESISTANT MICROBIAL STRAINS, ANTIMICROBIAL SENSITIVITIES AND RISK STRATIFICATION OF FIRST LINE ANTIBIOTIC USE IN ADULT CANCER PATIENTS WITH NEUTROPENIC SEPSIS

A. Danga[1,*], Y.M.T. Hui[2], K. Lazarus[3], T. Sugai[4]

[1]Haematology, North West London NHS Trust, [2]Haematology, West Middlesex University Hospital, [3]Renal Medicine, Imperial College Healthcare NHS Trust, [4]Haematology, Hillingdon Hospital NHS Trust, London, United Kingdom

Background: Neutropenic sepsis remains a leading cause of morbidity and mortality in both haemato-oncology and general oncology patients on cytotoxic treatment. In 2012, UK NICE published guidelines on the empirical use of beta lactam monotherapy in suspected neutropenic sepsis, discouraging the use of aminoglycosides, in view of potential toxicities. Increasingly in clinical practice it becomes evident that our patient population is incredibly heterogeneous and with the emergence of multi drug resistant strains of micro-organisms, high-risk individuals need to be identified early and first line antimicrobial treatment regimens tailored according to patient factors alongside local antibiogram.
Aims: To retrospectively review appropriate antibiotic use, microbial identifications and antibiotic sensitivities amongst adult cancer patients with neutropenic sepsis. To identify if any patient or disease characteristics are associated with adverse outcomes, that would support the upfront usage of aminoglycoside containing antibiotic treatment regimes.
Methods: A retrospective review of patients treated for neutropenic sepsis was conducted for the period between 1/4/2015 to 11/10/2016. Analysis of potential risk factors including primary disease, age, sex, treatment regimen, albumin, neutrophil and lymphocyte count to assess potential association with adverse outcomes.
Results: There were 116 episodes of neutropenic sepsis in 92 patients in this period. Of these, 61 were haemato-oncology patients and 31 general oncology. 42 of 76 positive cultures identified gram-negative organisms. 40 patients received single agent Tazocin and 71 patients (61.2%) received Tazocin and an aminoglycoside as first line antimicrobial treatment. Fourteen isolates demonstrated resistance, including 2 cases of stenotrophomonas maltophilia and 12 cases of enterobacteriaceae. 13 of the 14 resistant isolates were found in haemato-oncology patients. Nine of these cases were resistant to single agent Tazocin but sensitive to an aminoglycoside. The mean age of cases with resistant bacteria isolated was 54.2 years (range 25-84 years). There was no difference in sex or degree of neutropenia/lymphopenia in the cases that contracted resistant bacterial strains compared to those that were culture negative. Of the 4 fatal cases with resistant bacteria, 3 had low albumin (mean 25.5g/L cf. mean of 34g/L in resistant bacteria cases surviving).
Summary/Conclusions: This retrospective analysis supports the use of combination antimicrobials up front as first line treatment in high-risk patients with neutropenic sepsis. The study has demonstrated that the patient cohort most at risk of developing drug resistant bacteraemia are patients with high-risk or relapsed haemato-oncological disorders like AML or high-grade lymphoma, requiring multiple cycles of intensive chemotherapy. Of the patients who isolate resistant bacteria, identifying low albumin early may be a potential marker for adverse outcome in terms of morbidity and mortality. Of interest only one oncology patient isolated a resistant strain of bacteria, furthermore only 25% of general oncology patients treated with neutropenic sepsis had positive cultures compared to 79.8% of haemato-oncology patients. When comparing these findings to UK NICE recommendations it is clear that first line use of Tazocin in general oncology patients may well suffice in initial treatment of neutropenic sepsis. However with haemato-oncology patients early or up front consideration for the additional usage of an aminoglycoside is essential to optimize favourable outcomes in high-risk patients. From this small study, the proposed risk factors of isolating resistant strains of bacteria leading to adverse outcomes would be aggressive haematological malignancies, receiving more intensive cytotoxic therapy, multiple lines of treatment and low albumin. Further analysis in a multi centre prospective study in this patient population alongside close collaboration between clinicians and microbiologists is essential in providing optimal antimicrobial therapy algorithms in neutropenic patients.

E1149

PRELIMINARY RESULTS FROM A LONG-TERM REPEAT DOSE TOXICITY AND TOXICOKINETIC STUDY OF ANF-RHO, A NOVEL ANTI-NEUTROPENIC FACTOR

J. Valentino[1], H. Misra[1,*], J.A. Newmark[2]
[1]Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, [2]Toxicology, Toxikon, Bedford, United States

Background: ANF-Rho is a novel polyethylene glycol-modified granulocyte colony stimulating factor that has biophysical and biological properties that produce a prolonged pharmacokinetic and pharmacodynamic profile as compared to pegfilgrastim (Neulasta®). As such, it has potential applications in chemotherapy induced neutropenia and chronic idiopathic neutropenia. These disorders require prolonged administration of G-CSF agents to treat neutropenia. Therefore, long term toxicology, genotoxicity and Juvenile studies were conducted with ANF-Rho.
Aims: A 13-week study was conducted in Sprague Dawley rats and cynomolgus primates to assess various safety and pharmacokinetics of ANF-Rho as compared to Neulasta® (pegfilgrastim).
Methods: The study design used 288 rats, divided into 5 dosage groups: control, 100, 300, 1000 (high) and 1000 (positive) µg/kg. A total of 58 monkeys were also divided into 5 dosage groups: control, 75, 250, 750 (high dose) and 750 (positive) µg/kg of ANF-Rho. Doses were administered by weekly subcutaneous injections on Day 1, 8, 15, 22, 29, 36, 43, 50, 57, 64, 71, 78, 85 and 92 at a dose volume of 5 mL/kg. Genotoxicity assessments were evaluated using *Salmonella typhimurium* and *Escherichia coli* reverse mutation assay, rodent blood micronucleus assay and chromosomal aberration assay. Toxicology assessment included clinical observations, body weight change, food consumption, ophthalmic examination, function observational battery (motor activity, behavioral changes, coordination and sensory/motor reflex response), organ weight, bioanalytical and toxicokinetic analysis, immunogenicity, gross necropsy and histopathology.
Results: No observed clinical signs seemed to be related to ANF-Rho administration. There were no related effects in body weight changes or food consumption. Observed ophthalmic effects were considered procedural related due to low incidence. No biologically meaningful findings were noted during the function observational battery assessment. Preliminary analysis showed a dose related increase in spleen weight in rats and a dose dependent decrease in kidney weight in primates. Genotoxicity studies found no signs of mutagenicity, clastogenicity or cytotoxicity.
Summary/Conclusions: The results from this preliminary toxicology studies are unremarkable and consistent with those of an earlier 28-day study. Results from the 28-day rat neutropenia dosage model found that the blood pharmacodynamics parameters of ANF-Rho were significantly superior to PEG-filgrastim. Both PK and PD data demonstrate relatively predictable systemic exposures and activity following SC or IV dose levels in both rat and primate. It is anticipated that this long terms 13-week study will provide evidence of safety sufficient to support advancement of ANF-Rho into Phase II clinical studies in chemotherapy-induced neutropenia and chronic idiopathic neutropenia in Europe, USA and India.

E1150

USE OF MICAFUNGIN IN PROPHYLAXIS IN ONCO-HEMATOLOGY: RESULTS OF AN OBSERVATIONAL, MULTICENTER, PROSPECTIVE FRENCH STUDY (OLYMPE)

J. El-cheikh[1,*], J.-H. Dalle[2], S. Ducastelle-Leprêtre[3], J.-B. Quiniou[4], P. Ceballos[5], R. Herbrecht[6]
[1]American Hospital, Beirut, Lebanon, [2]Hôpital Robert Debré, Paris, [3]Hospices Civils, Lyon, [4]Medical Affairs, Astellas pharma France, Levallois-Perret, [5]Centre Hospitalo-Universitaire, Montpellier, [6]Centre Hospitalo-Universitaire, Strasbourg, France

Background: Antifungal prophylaxis is being used increasingly.
Aims: The therapeutic arsenal is extensive and requires a better understanding of micafungin use in onco-hematology where most-at risk patients of invasive fungal infections (IFI) are managed.
Methods: This observational study was conducted in 18 onco-hematology units in adult patients and children treated with micafungin in prophylaxis with a 3-months follow-up period.
Results: 150 patients (95 adults, 55 children) were included and represent the analysis population. In total, 15 patients (10%) presented an IFI during micafungin treatment. Among them, 11 presented a probable or proven IFI. The rate of IFI was higher in children (15%, n=8) than in adults (7%, n=7) and seem to have been influenced by the type of hemopathy and if the patient was allografted or not: 13% (n=8) in allografted patients, 9% (n=4) in patients with AML or SMD and 7% (n=3) in other patients. Median time to infection was 24 days (1 to 68 days) and was longer in adults (25 days, 4 to 68 days) than in children (16.5 days, 1 to 68 days). Twelve patients (8 children and 4 adults) presented at least one clinical or radiological sign of suspected IFI. Fungus was identified in 8 patients (62%), mostly in blood cultures (50%, n=4): candidiasis in 4 patients, aspergillosis in 3 patients and infection related to Rhisopus in 1 patient. Incidence rate of IFI (10%, 5 patients) was inferior to prophylaxis failure rate (23%, 34 patients). Prophylaxis failure rate takes in account patients who switched to empirical treatment besides patients who switched to preemptive or curative treatment. After the end of prophylaxis, 4 patients (3%, 3 adults and 1 child) presented a proven IFI. Median time to infection after the end of treatment was 10,5 days in adults (7 to 24 days) and 52 days in children. Micafungin was overall well tolerated: only 10 patients (7%, mostly children) presented grade 1 to 4 adverse events related to micafungin, including 5 patients (3%à with grade 3 or 4 adverse events.
Summary/Conclusions: Effectiveness and safety profile of micafungin in prophylaxis are similar to what was observed in previous studies. Incidence IFI rate of 10% confirms the clinical effectiveness of micafungin in prophylaxis in high risk patients. The low rate of serious adverse events confirms micafungin safety profile, in children included.

E1151

OUTBREAK OF MULTI-DRUG RESISTANT PSEUDOMONAS AERUGINOSA (MPA) IN A HAEMATOLOGY WARD (HW): MANAGEMENT AND INFECTION CONTROL MEASURES

D. Armiento[1,*], E. Cerchiara[1], O. Annibali[1], M. Becilli[1], E. Circhetta[1], S. Ferraro[1], A. Pagano[1], A. Scardocci[1], M. Tafuri[1], M. C. Tirindelli[2], G. Avvisati[1]

[1]Haematology and Stem Cell Transplantation Division, [2]Transfusion Medicine and Cell Therapy Division, Campus Bio-Medico University Hospital, Rome, Italy

Background: *Pseudomonas Aeruginosa* (PA) is a gram negative, ubiquitous, opportunistic pathogen. Its intrinsic resistance to many antibiotics and the selective pressure exerted by empiric antimicrobial use, led to the emergence of MPA in hematologic units, with high mortality and morbidity rates among infected immunocompromised patients (pts). Considering our MPA incidence of 9% in 2007/08, an outbreak developed at the HW of "Campus Bio-Medico" University Hospital of Rome, from 2009, despite the measures employed from the previous 2 years (health personnel sensitization, regular air and water filters changing, isolation precautions).
Aims: To describe the MPA outbreak occurred between 2009 and 2013.
Methods: Our HW, opened in 2007, is composed by 7 rooms, each with a private WC: 2 single, 1 double and 4 single, positive pressure, each with a filtered-zone, dedicated to stem cell transplanted pts. *Retrospective study*: From 01/2009 to 04/2013 we hospitalized 415 adult pts; of these, 106, at high infectious risk (HIR) for severe and prolonged expected post-chemotherapy neutropenia, have been routinely screened at admission with microbiological samples (nasal, pharyngeal and rectal swabs) and additional tests when clinically indicated. Because, during this period, we observed a dramatic incidence of MPA isolates, we fulfilled specific sequential measures, to assess potential reservoirs and breaks in infection control and to manage the outbreak, summarized by the following 4 phases: *phase A*: closing of HW from 29/04/2013 to 09/06/2013; *phase B*: serial pre and post-disinfection environmental sampling from each room: swabs from sink filters, bidet filter, shower filter, flush button, infusion pump, TV remote control, 70% ethylic-alcohol gel bottle, floor sink, bedpan and water samples from bedpan automatic washers (BAW); *phase C*: room environmental disinfection and microbial decontamination with nebulized H_2O_2 solution added with silver cations; *phase D*: disposal of BAW, introducing the sole use of disposable bedpans and planning an environmental sampling and disinfection program.
Results: On 04/2013 we revised *retrospective study* data: 82 pts carried bacterial isolates; of these, 48 (59%) had MPA, classified as colonisation in 13 pts (mainly detected on rectal swabs) and true infection in 35: 10 pneumonias (29%), 6 anorectal/perineal (17%), 5 urinary tract (14%), 14 bloodstream infections (40%). Ten pts died of MPA related infection, with a mortality of 53% (10 on 19 pts) and case-fatality rate of 29% (10 on 35 pts). *Phase B* defined a prevalence of PA isolates in 6 out of 7 rooms in different sample types, with 4 MPA isolates identified in 3 different BAW and 1 bedpan after washing cycle. After *phase C*, a new *phase B* demonstrated sterilization of 3 out of 6 PA and 3 out of 4 MPA isolation sites. As a main corrective action, after 41 days we resumed admissions and approached *phase D,* resulting into a prompt and maintained decrease in isolates (Table 1).

Table 1. MPA isolates and mortality rate after phase D.

	2013 (second half)	*2014*	*2015*	*2016*
HIR pts	**35**	**38**	**51**	**52**
Colonisation (%)	**0**	**1**(3)	**0**	**0**
Infection (%)	**2**(6)	**1**(3)	**1**(2)	**0**
Mortality (%)	**0**	**0**	**0**	**0**

Summary/Conclusions: We identified the contaminated water residue from BAW as the main source of MPA spread in our HW, getting a full outbreak control by improving environmental measures. Pseudomonas contaminates and survives on many ecological niches, being continuously reintroduced in nosocomial settings. Our experience highlights the value of environmental and personal hygiene measures on MPA infections control.

E1152

MONITORING VORICONAZOLE PHARMACOGENOMICS AND PLASMA CONCENTRATIONS IN THE TREATMENT AND PREVENTION OF INVASIVE FUNGAL DISEASE FOR HEMATOLOGICAL PATIENTS A SINGLE CENTER EXPERIENCE

D. Guo[1], T. Xu[1], Z. Li[1], J. Yin[1], X. Tian[1], D. Guo[1], Y. Xu[1], X. Zhu[1], L. Miao[1], D. Wu[1,2], X. Tang[1,2,*]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Voriconazole has been widly used in treatment and prevention invasive fungal disease for immunodeficiency hematological patients. And the voriconazole plasma drug levels were associated with its efficacy and toxicity. The hepatic cytochrome P450 isoenzyme 2C19 plays a important role in voriconazole metabolism. However if CYP2C19 genetic polymorphism can result in voriconazole metabolism and drug plasma level in setting of Asian population especially in hematologic patients is unknown.
Aims: To evaluate the effect of CYP2C19 polymorphism on the voriconazole (VCZ) plasma concentration of patients with hematological disease and the value of serial monitoring voriconazole plasma concentrations in the treatment and prevention of invasive fungal disease(IFD).
Methods: Between January to August 2016, 76 hematological patients who received voriconazole for the treatment or prevention of invasive fungal disease were enrolled in this study. The population CYP2C19 polymorphism of voriconazole were performed using PCR-Pyrosequencing. The trough plasma concentrations of vriconazole (C_{trough}) was determined using high-performance liquid chromatography (HPLC).
Results: Genotyping for CYP2C19 polymorphic isoenzyme variations showed that 32 subjects (43.42%) for the CYP2C19 wild-type, 43 (56.58%) for the CYP2C19 no-wild-type. 2. 45 of 76 patients received voriconazole intravenous administration, Based on the genotype analysis, 45 subjects were identified as extensive metabolizers' group for EMs (CYP2C19*1/*1), poor metabolizers' group for IMs+PMs (CYP2C19 * *1/*2,*1/*3,*2/*3,*2/*2,*3/*3)□and there was a significant difference between C_{trough} values in the two groups (1.66±1.86ug/ml *vs* 3.30±2.35ug/ml, p=0.00). 3. The C_{trough} of the 45 patients were detected for 119 times totally. The medium of the C_{trough} 45 hematological patients were described. Lack of response to therapy was more frequent in patients with voriconazole levels <1.5mg/L (23.5%) than in those with voriconazole levels >1.5mg/L (21.4%])(p=0.87). And the risk of adverse events was more frequent in patients with voriconazole levels >5.5mg/L (40.0%) than in those with voriconazole levels <5.5mg/L (25.0%) (p=0.49). Furthermore, the C_{trough} values of patients with adverse events is higher than the others(3.21±2.46ug/ml *vs* 2.17±2.14 ug/ml, p=0.042).
Summary/Conclusions: The single-center study showed that the mutation of CYP2C19 was quite common in Chinese hematological patients. Patients with CYP2C19 wild-type phenotype are extensive metabolizers, their C_{trough} of voriconazole are significantly lower than patients with CYP2C19 non-wild-type phenotype (poor metabolizers). Appropriate concentrations of vriconazole can improve the effiency of therapy and safety outcome.

E1153

BACTEREMIA AND SEPSIS FOLLOWING INTENSIVE CHEMOTHERAPY OF ADULT ONCOHEMATOLOGICAL PATIENTS

S. Bessmeltsev[1,*], V. Chebotkevich[2], E. Kiseleva[2], N. Stizhak[2], E. Kaytandzhan[2], V. Burylev[2]
[1]Haematilogy, [2]Lab. Bacteriology, Russian Institute of Haematology andTtransfusiology, St. Petersburg, Russian Federation

Background: Intensive cytostatic chemotherapy is a standard strategy for leukemia treatment. Meanwhile, such treatment causes negative effects, including lymphopenia, granulocytopenia and damage to tissue barriers associated with significant risks of infectious complications, especially, bacterial sepsis and viremia.
Aims: Our study was aimed for identification of bacteremia in oncohematological patients following intensive chemotherapy, and assessment of potential modifying role of herpesvirus infections.
Methods: Retrospective review of positive bacterial isolates of blood between January 1991- December 2015. Prospective study the cases of bacteremia and sepsis in cohort of 64 patients with hematologic malignancies. Diagnostics of septic conditions was based on clinical data, bacteremia and systemic inflammatory reaction syndrome (SIRS) (registration of, at least, 2 of 4 clinical symptoms of SIRS). Bacteriological analyses and identification of micromycetes were performed by uniform technique over the entire study period, according to the valid guidelines. For DNA-diagnostics, we used gene-specific PCR with real-time registration. DNA was extracted from peripheral blood leukocytes The herpesvirus panel included Herpes Simplex type 1 and 2 (HSV); Cytomegalovirus (CMV); Epstein-Barr virus (EBV), and Human Herpesvirus type 6 (HHV6). PCR techniques were performed according to manufacturer instructions.
Results: Based on the study 4923 blood samples it was shown that the frequency of detection of bacteria was 11.0%. The predominance of Gram-positive bacteria was demonstrated among pathogens detected in the bloodstream. However, the ratio of detectable Gram-negative flora was found to be increased from 23.1% to 39.6% between 2002 and 2015 (p<0.05). Coagulase-negative staphylococci (CoNS) prevailed among Gram-positive microorganisms, in particular, *S. epidermidis*, whereas *Enterobacteriaceae*, especially, *E.coli*, dominated among the Gram-negative bacteria. It is shown that the development of bacteremia were significantly more frequently occurs on the background of the detection of Cytomegalovirus and the Epstein-Barr virus genomes. In recent years there has been increase the frequency of micromycetes detection in the blood of patients with hematological malignancies. In present study, antibacterial therapy started with β-lactame antibiotics combined with fluoroquinolones, aminoglycosides, metronidazole. If required, the antimicrobial strategy was revised 48 to72 hours later as based on clinical and microbiological data, applying carbapenems also combined with other anti-infectious drugs. When detecting herpesviruses (EBV, HSC-1/2, HHV6, or CMV) the therapy was accomplished by antiviral drugs, *i.e.*, Acyclovir or Valacyclovir (for CMV treatment). Sepsis in accordance with the criteria (SIRS and bacteremia) was diagnosed in 33 of 64 patients. Mortality was higher in patients with Gram-negative sepsis – 8 of 14 patients (57%) whereas in Gram-positive sepsis 2 of 19 patients (11%).
Summary/Conclusions: Our data support a general viewpoint on regular monitoring of infectious pathogens upon intensive chemotherapy of oncohematological patients prone to both bacterial and viral infections. Severe bloodstream infectious complications are often associated with fungal invasions, and herpesvirus reactivation. In particular, our results suggest that herpesviruses, may cause immunosuppression, or may serve as additional immunodeficiency markers predictive for bacterial infections at later terms.

Iron metabolism, deficiency and overload

E1154

GLYCOSYLATED FERRITIN MEASURING SIGNIFICANCE FOR SECONDARY HEMOPHAGOCYTIC SYNDROME DIAGNOSTICS

V. Potapenko[1,*], M. Pervakova[2], S. Lapin[2], A. Klimovich[1], O. Mironova[1], N. Petrova[1], N. Chernookaya[1], N. Skorobogatova[1], E. Karyagina[3], E. Karev[4], E. Pavluchenko[4], N. Potikhonova[5], T. Kulibaba[6], N. Medvedeva[1], B. Afanasyev[2]
[1]Municipal clinical hospital №31, [2]Academician I.P. Pavlov First St. Petersburg State Medical University, [3]Municipal hospital №15, [4]I.I. Mechnikov North-Western State Medical University, [5]Russian Scientific Research Institute of Hematology and Transfusiology, [6]Saint-Petersburg State University, Saint-Petersburg, Russian Federation

Background: Hemophagocytic syndrome (HPS) is a clinicopathologic condition characterized by systemic inflammatory reaction with cytopenia and tissue damage. The HPS may be primary (genetic associated) or secondary (SHPS), caused by different systemic disorders (immune, infectious, neoplastic). The overall clinical symptoms are similar to sepsis, so it could be difficult to differentiate among these entities. Ferritin levels are high in both cases, but the glycosylated/nonglycosylated ferritin fractions ratio is seems to be indicative.
Aims: The estimation of the ferritin fractions ratio and biochemical profile in patients with sepsis and SHPS.
Methods: The data from 64 patients were analyzed: 40 pts with diagnosed SHPS (median age 57, range 8-74 years) and 24 with lethal septic shock (median age 57.5, range 18-82 years). SHPS in patients with persistent fever refractory to antibacterial therapy and/or prolonged cytopenia and/or organ (lungs, CNS) involvement was established after the other conditions had been excluded. Sepsis diagnostics was based on the confirmed infection site and systemic inflammation with multiorgan failure. The following serum values were analyzed: alkaline phosphatase (AlPh), alanine aminotransferase (ALAT), asparagine aminotransferase (ASAT), lactate dehydrogenase (LDH), bilirubin, creatinine, INR, C-reactive protein (CRP), procalcitonin (PCT), total ferritin, and glycosylated ferritin percentage. Mann-Whitney U test and ROC-analysis were used for statistical analyses.
Results: No differences were found in sepsis and SHPS for ALAT, ASAT, AlPh, LDH, and bilirubin levels. The difference of INR, CRP, PCT, creatinine levels was significant (p<0.01). The most substantinal difference in SHPS and sepsis groups had serum concentrations of ferritin, triglycerides, level of ferritin glycosylation (p<0.01) (Table 1). According to ROC-analysis, the area under the curve for ferritin, triglycerides and percentage of ferritin glycosylation were 0.78, 0.82, and 0.92, respectively.

Table 1.

	Dimension	median	25 quartile	75 quartile
Ferritin-SPHS	Ng/ml	7635	2863	13559
Ferritin –sepsis	Ng/ml	2163	1094.7	3940.5
Glycosylation ferritin – SPHS	%	21	10	33
Glycosylation ferritin - sepsis	%	40.1	33.7	55.9
Creatinine – SPHS	Mcmol/l	90	72	142
Creatinine – sepsis	Mcmol/l	186	126.5	302.5
Triglycerides – SPHS	Mmol/l	3.1	2.2	4.1
Triglycerides – sepsis	Mmol/l	1.38	0.75	2.37
C-reactive protein – SPHS	Mg/l	80.6	25.3	183
C-reactive protein – sepsis	Mg/l	214.5	185.9	287.5
Procalcitonin – SPHS	Ng/l	1.65	0.71	2.29
Procalcitonin – sepsis	Ng/l	55.9	38.9	198.35
International Normalized Ratio - SPHS		2.37	1.02	2.03
International Normalized Ratio - sepsis		1.73	1.47	2.4

Table 1. Significant laboratory differences (p<0.01), SPHS – secondary hemophagocytic syndrome.

Summary/Conclusions: The most difference between sepsis and SHPS was observed for triglycerides, ferritin and percentage of glycosylated ferritin. Percentage of glycosylated ferritin fraction seems to be the most indicative, which may make it useful for SHPS diagnostics and its differentiation from sepsis.

E1155

SERUM HEPCIDIN QUANTIFICATION IN INFLAMMATORY BOWEL DISEASES

V. Manolov[1,*], V. Vasilev[1], K. Tzatchev[1], O. Georgiev[2], D. Stefanova-Petrova[2], R. Tzrantcheva[2], V. Mitev[3]
[1]Dept. of Clinical laboratory and clinical immunology, [2]Department of Propaedeutics of Internal diseases, [3]Department of Medical chemistry and biochemistry, Medical University, Sofia, Sofia, Bulgaria

Background: Inflammatory bowel diseases (IBD) includes different intestinal pathologies, most common among them are Colitis Ulcerosa (CU) and Crohn's Disease (CD). Pathogenesis of IBD is still unclear, however they are multifactor diseases, with genetic and autoimmune compounds, in combination of environmental factors. One of IBD symptoms is iron deficiency anemia.
Aims: We aimed to search for connection between serum hepcidin quantification and anemia in IBD.
Methods: We included 64 patients with IBD - 29 with Colitis Ulcerosa (CU), and 35 with Crohn's Disease (CD). They were diagnosed in University "Aleksandrovska" hospital in Clinic of Gastroenterology. Their results were compared to age and gender matched healthy controls. Laboratory assessments were analyzed for included groups – iron, ferritin, CRP, IL-6 and hepcidin. AAS, nephelometric, ELISA and statistical methods were used during analyzes and obtained results interpretation.
Results: 53 from our patients had with iron deficiency anemia (IDA) and low hepcidin concentrations (5.9±1.1 µg/L) compared to control group (19.9±2.8 µg/L); *P*<0.001. 11 of included cases had combination of IDA and anemia of chronic disease (ACD). Their hepcidin levels were increased (59.9±6.4 µg/L) in comparison to healthy controls (19.9±2.8 µg/L); *P*<0.001. In patients with ACD/IDA, quantified serum hepcidin correlates positively to increased IL-6 (r=0.758, *P*<0.005) and CRP concentrations (r=0.899, *P*<0.001).
Summary/Conclusions: Quantification of serum hepcidin levels in IBD patients might be a key element in diagnosis and treatment of anemia in these patients. Serum hepcidin levels are useful marker for differential diagnosis between iron deficiency anemia and combination iron deficiency anemia/ anemia of chronic disease.

E1156

MUTATIONS IN YARS2 CAUSE CONGENITAL SIDEROBLASTIC ANEMIA WITHOUT SHOWING EVIDENCES OF MYOPATHY AND LACTIC ACIDOSIS

B. Cadenas[1,*], J. Fita[1], S. Montesdeoca[2], C. Pedro[2], M. Sanchez[1]
[1]Iron Metabolism: Regulation and Diseases, Josep Carreras Leukaemia Research Institute (IJC), BADALONA, [2]Hematology Service, Hospital del Mar, Barcelona, Spain

Background: Mutations in the gene *YARS2* encoding mitochondrial tyrosyl-tRNA synthetase have previously been identified as a cause of MLASA2, a mitochondrial respiratory chain disorder presenting with myopathy, lactic acidosis and congenital sideroblastic anemia (OMIM #610957, ORPHA 2598). Up to date in the literature it has been reported 9 families with 11 affected individuals with mutations in *YARS2* gene and affected from MLASA2.
Aims: Here we report a new case with a different clinical presentation.
Methods: We have identified two novel variations in *YARS2* gene using Next Generation Sequencing (NGS) panel containing 10 genes involved in congenital and acquired sideroblastic anemia.
Results: The proband is a young woman aged 24 where we have identified 2 novel variations in *YARS2* gene. One pathogenic splicing mutation NM.001040436.2 c.[1104-1G>A], and a missense variation NM.001040436.2 c.608 G>T; NP_001035526.1: p. Ser203Ile located in the C-core catalytic domain of the mitochondrial tyrosyl-tRNAsynthetase. None of these two variations were previously reported in public databases (ExAC, NCBI SNP, Ensembl). Clinical data from the patient showed marked sideroblastic anemia (Hb 91 g/L, 32% ring sideroblasts), but not signs of muscle weakness or myopathy and no lactic acidosis (lactic acid levels were 1.8mmol/L, normal range: 0.5 - 2.2 mmol/L; creatine kinase 23 UI/L, normal range: 23-170 UI/L), as could be expected due to previously reported cases in the literature. Functional assays are on-going to confirm pathogenicity of the novel missense variation.
Summary/Conclusions: Here, we reported a patient with mutation in *YARS2* gene showing congenital sideroblastic anemia but presenting neither lactic acidosis nor myopathy. Therefore, patients with defect in *YARS2* gene may present with a less severe clinical manifestations only involving congenital sideroblastic anemia without other extra-hematopoietic defects. MLASA2 must be consider in patients presenting with only congenital sideroblastic anemia since early diagnosis and supportive therapy will be important to prevent complications.

E1157

IRON CHELATION DATA OF CONGENITAL DYSERYTHROPOIETIC ANEMIA PATIENTS: A SINGLE CENTER EXPERIENCE

M. Cetin[1,*], N. Kalkan[1], T. Bayhan[1], F. Gumruk[1], S. Unal[1]
[1]Hacettepe University, Divison Of Pediatric Hematology, Ankara, Turkey

Background: Congenital dyserythropoietic anemia (CDA) is a rare, genetically heterogenous disorder characterized with ineffective erythropoiesis, and congenital malformations in certain types. Patients present with varying degrees of anemia and some of the patients may have mild disorder wheras others may be transfusion dependent. The ineffective erythropoiesis and the transfusional iron load puts these patients at risk for iron overloading and there is very scarce data on the iron loading and chelation types in these patients.
Aims: We aimed to summarize the chelation results of our patients with CDA from a single center.
Methods: Of the 33 patients with CDA, 11 were initiated iron chelation treatment either for receiving more than 20 packed RBC transfusions previously or for having serum ferritin levels above 1000ng/ml.

Results: Of these 11 patients, 7 were CDA type II. The median age of diagnosis was 12 months (3-144) months and male to female ratio was 7/4. Median transfusion requirement per year at previous year prior to initiaition of chelation was 12 times (0-17). All of the patients were on chronic transfusion programme at initiation of iron chelation except for 2 (one receives occasional transfusion, and the other patient was on chronic transfusion programme but became treansfusion independent after splenectomy). The median age at last visit was 70 months (32m-40 years). The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assesment prior to and by the end of 1 year of chelation aand none of the patients were found to have cardiac iron loading at chelation initiation, wheras 2 had severe and 1 had moderate LIC values. In the subsequent assesment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, wheras 1 had mild and 2 had moderate LIC values. Serum ferritin levels prior to chelation initiation and by the end of 1 year were compared and the difference was found statistically insignificant.
Summary/Conclusions: Patients with CDA are at risk for iron loading and they need to be screened for the iron loading periodically. The prompt chelation in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.

E1158

ORAL IRON CHELATION FOR TREATMENT OF HEREDITARY HEMOCHROMATOSIS IN CHILDREN

M. Moraki[1,*], E. Repousi[1], D. Kyriakopoulou[1], P. Delaporta[1], A. Kattamis[1]
[1]Thalassemia Unit,First Department of Pediatrics, National and Kapodistrian University of Athens, 'Aghia Sophia' Children's Hospital, Athens, Greece

Background: Hereditary hemochromatosis (HH) very rarely presents during childhood. The most common form of HH in children is Juvenile Hemochromatosis (JH), a rare genetic disorder inherited with an autosomal recessive manner, resulting from mutations in either the hemojuvelin (HJV) (type 2A) or the hepcidin (HAMP) gene (type 2 B). Early diagnosis and closely monitoring of iron overload indexes, namely, serum ferritin levels, transferrin saturation and tissue iron measurement by magnetic resonance imaging (MRI) are essential in order to prevent permanent organ damage and potentially life threatening complications (cirrhosis, diabetes mellitus, cardiac dysfunction, and hypogonadism). Therapeutic intervention in children with HH may be problematic, as eryhtrapheresis is invasive and may not be well tolerated in young children. Iron chelation therapy can be implemented as an alternative treatment to erythrocytapheresis.
Aims: The scope of this study was to evaluate the use of an oral iron chelation therapy in young children with HH.
Methods: 3 children (2 females and 1 male) were diagnosed with HH at the aged of 4, 6 and 8 years old, respectively, based on increased ferritin and transferrin saturation levels and exclusion of other not-iron-overload related causes of hyperferritinemia. Genetic analysis were performed in all 3 patients and showed positive results in 2 of them, while on the 3rd no genetic changes could be identified. All patients were at pre-symptomatic stage of the disease and they were referred for evaluation after hyperferritinemia was discovered on a routine screening examination. Liver iron concentration (LIC) and cardiac iron concentration were evaluated by MRI (table 1). Iron chelation therapy with deferasirox (DFX) at low dose (of 10mg/kg/24h) was initiated, after evaluation was completed and permission from regulatory authorities obtained.

Table 1. Clinical characteristics of the patients.

	Age (years) at treatment	Genotype	Ferritin at treatment (ng/dl)	Transferrin saturation (%)	LIC (mcgr Fe / g.d.w.tissue)	Cardiac Iron-T2* (msec)
1	7	HJV:G320V/N HFE:S65C/N	728	90%	12.6	32.9
2	6	HJV:G320V/G320V	584	71%	10.4	30.7
3	10	unknown	309	55%	1.1	18.5

Results: All 3 patients responded promptly to therapy and showed decreased levels of ferritin, LIC and cardiac iron concentration. Gastrointestinal disturbances were noted in 1 patient, which resolved with H2-blockers and with changing the treatment to 5d/wk (patient 2). Mild increase in serum creatinine (>33% from baseline but within normal range for her age) was observed in patient 3, which resolved with temporary cessation of the chelation therapy.
Summary/Conclusions: HH is very rare disorder in children, most frequently due to JH. Timely initiation of treatment to prevent iron overload consequences is essential. Chelation therapy with deferasirox is efficacious with a manageable toxicity profile and it can be considered as an alternative therapeutic option to chronic erythrocytapheresis for the treatment of JH.

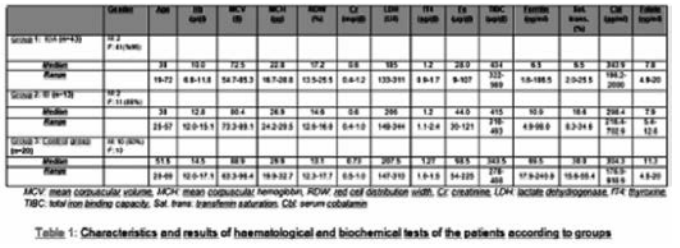
E1159

NEUTROPHIL HYPERSEGMENTATION IN ADULTS WITH IRON DEFICIENCY: A CASE-CONTROL STUDY

I. Erdogan Ozunal[1,*], D. Keskin[1], E. Durcan[2], Y. Gunay[2], S. Bilgin[2], S. Berk[1], D. Ozmen[1], N. Ozgur Yurttas[1], S. Sadri[1], A. Salihoglu[1], A.E. Eskazan[1], M.C. Ar[1], S. Ongoren[1], Z. Baslar[1], Y. Aydin[1], A.L. Yaldiran[2], T. Soysal[1]
[1]Department of Internal Medicine, Division of Hematology, [2]Department of Internal Medicine, Istanbul Universitiy Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Neutrophil hypersegmentation (NH) has been accepted as a hallmark of the macrocytic anaemias associated with the deficiency of cobalamin or folate. However, there are a small number of reports stating that NH might accompany iron deficiency anaemia. The aim of the present study was to determine the association of NH with iron deficiency (with or without anaemia).
Aims: The aim of the present study was to determine the association of NH with iron deficiency (with or without anaemia) in adults and also to compare neuthrophil segmentation status in anemia group before and after oral or parenteral iron treatment .
Methods: Fifty-six patients with iron deficiency and 20 age and sex matched controls were included in this prospective, single blind, case-control study between February-November 2016. Subjects were included if they were ≥ 18 years of age, and had normal serum vitamin B_{12} and folate levels, liver, thyroid and renal function tests. Pregnant women and patients with a history of blood transfusion within last 3 months and/or those with acute renal failure, anaemia of chronic disease, hypothyroidism, additional cytopenias and infection were excluded. Patients with iron deficiency were divided into 2 groups being with iron deficiency anemia (IDA) and iron deficiency without anaemia (ID). Those with anaemia were further evaluated prior and after iron replacement. Results of the study groups were compared to age and sex matched healthy controls. Blinded peripheral blood smear slides were evaluated by a haematologist by counting 200 neutrophils. Hypersegmentation was defined as reported by Bain et al.. Iron deficiency was diagnosed based on the findings of iron parameters including serum iron, total iron binding capacity, and ferritin. Anaemia was defined according to the WHO recommendation. Cohort characteristics were given in Table 1.

Table 1.



MCV: mean corpuscular volume, MCH: mean corpuscular hemoglobin, RDW: red cell distribution width, Cr: creatinine, LDH: lactate dehydrogenase, FT4: thyroxine, TIBC: total iron binding capacity, Sat. trans: transferrin saturation, Cbl: serum cobalamin

Table 1: **Characteristics and results of haematological and biochemical tests of the patients according to groups**

Results: Hypersegmentation was detected in 25 individuals with iron deficiency (45%) and 1 healthy control (5%). It was significantly more frequent in the IDA group (48.8%) than in the ID group (30.7%) [p<0.001]. After iron treatment 3 IDA patients' peripheral blood smear were checked and with normalization of iron parameters and hemoglobin, hypersegmentation was undetectable. The study is still ongoing and rest of the IDA group are still on treatment, their peripheral blood smears are to be examined after iron treatment is over.

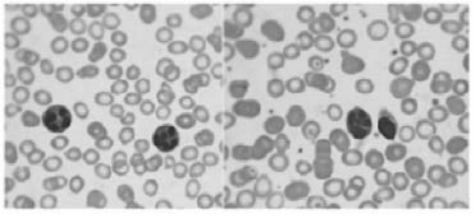


Figure 1: **Hypersegmentation of neutrophils in two different patients with IDA**

Figure 1.

Summary/Conclusions: Although the mechanism of neutrophil hypersegmentation in iron deficiency anaemia is not clear, it is thought that iron acts as a cofactor in folate metabolism and / or DNA synthesis in granulocytes. There are a limited number of studies dealing with NH associated with IDA in the literature. However most of these studies were observational and did not include controls or were not blinded. Our study is the first to demostrate the association of NH with iron deficiency anaemia in adults in the absence of megaloblastic anemia.

E1160

M-TOR INHIBITORS-ASSOCIATED MICROCYTIC ANEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

R. Angel F.[1,*], A. Monter[1], A. Esquirol[1], R. Martino[1], I. Garcia-Cadenas[1], J. Remacha[1], S. Payan[1], S. Brunet[1], J. Sierra[1]
[1]Hematology, Hospital de Sant Pau, Barcelona, Spain

Background: Immunosuppression with mTOR inhibitors (sirolimus or everolimus) has been associated with development of microcytic anemia after solid organ transplantation. The prevalence reaches 27 to 57% in the case of kidney transplantation. This anemia has been attributed to hepcidin increase induced by the inhibition of mTOR protein[1,2].
Aims: To evaluate the prevalence of microcytic anemia after allogeneic hematopoietic stem cell transplantation in patients receiving mTOR inhibitors.
Methods: 61 consecutive allogeneic stem cell reduced intensity conditioning (alloRIC) recipients were analyzed. In all cases, a non-related donor was used. Baseline disease was: 23 acute leukemia (37.7%), 12 non-Hodgkin lymphomas (19.7%), 10 myelodysplastic syndromes (16.4%), 7 Hodgkin lymphomas 7 (11.4%), 4 multiple myelomas (6,5%),3 chronic lymphocytic leukemia (4.9%), and 2 myelofibrosis (3.2%). All of them received Fludarabine-based conditioning treatment and the combination sirolimus (mTOR inhibitor)-tacrolimus (calcineurin inhibitor) as GVHD prophylaxis. Drug d*oses were adjusted* according to blood levels and renal function. Levels of Hb, MCV and iron parameters were systematically evaluated after alloRIC. Microcytosis was considered when MCV was below 80 fl.
Results: At 6 months 56 out of 61 (92%) were alive. Anemia was observed in 30 (49%) of them, with only 8 cases (13.1%) showing Hb level below 100 g/l. Microcytic anemia was diagnosed in 2 of them (3.3%). One patient showed an iron deficiency anemia due to gastrointestinal bleeding (Hb 94 g/l, MCV 69 fl, serum ferritin 21 µg/l). However, the second one, a 61-year old male with an acute leukemia, had a microcytic anemia with iron parameter changes similar to those observed in kidney transplantation and associated with increased hepcidin, (see table).Anemia progressively improved with sirolimus tappering.

Table 1.

	Pre-inh mTOR	Inh mTOR	Post inh m-TOR
Hb g/l	113	95	127
MCV fl	87	74	79
Platelets x 109/l	169	217	220
Leucocytes x 109/l	6.8	6,4	6,3
Fe/TIBC /% SAT µmol/l (NV: 8-26/ 44-73/15-45)	5/43/12	3/42/7	-
Serum ferritin µg/l (NV:20-350)	1467	1177	2349
Serum transferrin receptor mg/l (NV: 1.-3.5)	-	8.6	
Hepcidin (NV 1-39 mg/ml)	-	40.5	-
BM Macrophage iron % sideroblasts	-	Increased 6%	-

Inh: inhibitors. Hb: hemoglobin. MCV: mean corpuscular volume. Fe: iron. TIBC: total iron binding capacity. %SAT.% transferrin saturation. BM: bone marrow. NV: normal values.

Summary/Conclusions: In contrast to kidney transplantation, microcytic anemia related to immunosuppression with mTOR inhibitors was seldom observed in alloRIC recipients. However, this association should be taken in account in this setting, as a rare cause of anemia. In case of microcytic anemia, the evaluation of iron parameters and hepcidin provides the diagnosis of this rare type of anemia.

E1161

IRON METABOLISM IN PATIENTS WITH PAROXISMAL NOCTURNAL HEMOGLOBINURIA

E. Lukina[1,*], K. Tandilova[1], N. Tsvetaeva[1], O. Nikulina[1], E. Sysoeva[1], I. Karpova[2], E. Mershina[3], V. Sinitsyn[3]
[1]Department of Orphan Diseases, [2]Central Clinical Diagnostic Laboratory, National Research Center for Hematology, [3]Radiology Department, Federal Center of Treatment and Rehabilitation, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal non-malignant hematological disorder that is associated with hemolytic anemia, bone marrow failure, thrombosis. At the onset the condition is often interpreted as iron deficiency anemia that leads to the prescription of ferrotherapy.
Aims: Study iron metabolism in patients with PNH.
Methods: The study group included 19 patients (11 men and 8 women aged from 20 to 64 years, median age 43 years) with a diagnosis of PNH, followed up in our Center between 2014 and 2017. The median hemoglobin level was 8,1 g/dl. The erythrocyte PNH clone size ranged from 17 to 99%, median - 47%. Granulocyte and monocyte PNH clone sizes were 85% and 89%, respectively. The following parameters were studied to characterize iron metabolism: ferritin, transferrin, iron concentration, total iron binding capacity (TIBC), transferrin saturation. Ten of 19 patients undergone magnetic resonance imaging (MRI) of the liver and kidneys to determine iron overload. Five of 10 patients received treatment with eculizumab.
Results: Iron metabolism parameters varied in wide limits. Iron deficiency was detected in 4 (21%) patients, 8 (42%) patients had laboratory signs of iron overload, remaining 7 (37%) patients had normal parameters of iron metabolism. Ferritin rates ranged from 6 to 3050 ng/ml (median – 544ng/ml), transferrin – from 75 to 452mg/l (median – 238mg/l), TIBC –from 21 to 95 umol/l (median – 55umol/l), transferrin saturation – from 9 to 92% (median – 43%), iron concentration – from 5 to 50 umol/l (median – 22umol/l). MRI (including T2*-weighted images) revealed signs of liver hemosiderosis varying from mild to severe degree in 7 out of 10 studied patients. Signal intensity of renal cortex was decreased in 9 out of 10 patients, presumably due to renal hemosiderosis. In 1 patient there were no pathological findings on MRI. Laboratory signs of iron deficiency were revealed in 2 out of 9 patients with renal hemosiderosis. Signs of renal hemosiderosis were absent only in 1 out of 10 examined patients. This patient has been treated with eculizumab for 15 months.
Summary/Conclusions: Evaluation of laboratory parameters of iron metabolism is not sufficient to identify tissue iron overload in transfusion-dependent patients with PNH. MRI (including T2*-weighted images) revealed signs of hemosiderosis of liver and kidneys in 7 (37%) and 9 (47%) patients respectively, indicating the feasibility of this method for diagnosis of post-transfusion iron overload in patients with PNH and assessment of the need for chelation therapy. Described case of the patient who has no signs of renal hemosiderosis and receives treatment with eculizumab fortifies the results of clinical studies showing the efficacy of eculizumab in the prevention of renal failure in patients with severe PNH.

E1162

ORAL IRON ELEVATES SERUM IRON AND CONSEQUENTLY CHANGES IRON DISTRIBUTION IN LIVER AND ERYTHROCYTES

Y. Matsuo-Tezuka[1,*], M. Noguchi-sasaki[1], M. Kurasawa[1], K. Yorozu[1], Y. Shimonaka[1], M. Hirata[1]
[1]Product Research Department, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan

Background: For renal anemia patients, there are several therapeutic options including erythropoiesis-stimulating agents (ESAs), intravenous and oral iron supplementations. In terms of iron absorption, ESAs were known to activate iron absorption via down-regulation of hepcidin, a key mediator of iron metabolism, and consequent up-regulation of duodenal iron transporters divalent metal transporter 1 (DMT1) and ferroportin (FPN). On the other hand, in our previous study, intravenous iron was demonstrated to deactivate iron absorption system via hepcidin elevation. However, iron absorption under oral iron supplementation have not fully evaluated yet.
Aims: In this study, we investigated the activity of iron absorption under oral iron supplementation in mice as well as under intravenous iron supplementation. In addition, we also analyzed iron distribution under intravenous and oral iron supplementation.
Methods: To load iron orally, a diet including 200 ppm of iron was used as control and a diet including approximately 5000 ppm of ferric citrate was used as iron-rich diet. 6-week-old male C57BL/6NCrl mice were divided into 3 groups; control group, intravenous iron (IV iron) group, and oral iron (Oral iron) group (n=5). Mice in IV iron group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of iron-dextran on days 9. Mice in Oral iron group were fed an iron-rich diet from days 0 and intravenously administered 0.4mg/mouse of dextran as vehicle on days 9. Mice in control group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of dextran on days 9. All mice were euthanized by exsanguination under anesthesia with isoflurane on days 14. For analyses of iron absorption, serum hepcidin and iron were measured and expression of duodenal DMT1 and FPN were evaluated immunohistochemically. For analyses of iron distribution, berlin blue staining for liver and hematological indices were evaluated.
Results: Serum hepcidin levels in IV and Oral iron groups were significantly higher compared with control group. However, serum iron levels were elevated only in oral iron group. In immunohistochemical analyses, expression levels of duodenal DMT1 were not detected in all groups and expression levels of duodenal FPN in IV and Oral iron groups were significantly lower than control group. As for iron distribution in liver, iron was accumulated in reticuloendothelial cells in IV iron group, on the other hand, in Oral iron group iron was accumulated in parenchyma. In hematological analyses, although red blood cell and reticulocyte count were not significantly different among all groups, Ret-He and MCH in Oral iron group were higher than IV iron groups.
Summary/Conclusions: It was demonstrated in this study that serum iron levels were elevated in spite of high hepcidin levels and down-regulation of duodenal iron transporters under oral iron supplementation. Furthermore, iron was distributed in liver parenchyma and hemoglobin contents in each reticulocyte and erythrocyte were up-regulated only under oral iron supplementation. We speculated that high serum iron lead to excess iron uptake into tissues and erythrocyte fraction. These data might provide an opportunity to rethink the importance of proper use of iron supplementations.

E1163

DEFERASIROX FOR SEVERE ANAEMIAS IN YOUNG CHILDREN

A. Gunawan[1,2,*], S. Korenev[3], H. Mundy[3], M. Pelidis[3], J. Alamelu[3], B. Inusa[3]
[1]Haematology, Guy's and St Thomas' NHS Trust, [2]Pediatric, Evelina Hospital, Guy's and St Thomas' NHS Trust, [3]Pediatric, Evelina Hopsital, Guy's and St Thomas' NHS Trust, London, United Kingdom

Background: Children with haemoglobinopathy and rare anaemias often require regular red cell transfusions at some stage of their lives. Iron overload is therefore inevitable and iron chelation is a key component of therapy for children in this group. However its use has not been validated especially in children under two years of age. Deferasirox (Exjade®; Novartis Pharma AG, Basel, Switzerland) is an iron chelator that is conclusively proven to be effective and safe in transfusional anaemia such as haemoglobinopathies.
Aims: We aim to look at the efficacy and safety of Deferasirox in children with severe anemias.
Methods: We present a case report of 6 children with severe anemias treated with Deferasirox in a tertiary pediatric hematology centre in London, UK.
Results: Here we report 6 cases where deferasirox has been used in young children with rare anaemias and sickle cell disease. Patients 1 and 2 presented within the first year of life with pancytopaenia requiring regular transfusion and were diagnosed with Pearson syndrome. Deferasirox was started at the age of 30 months and 4 months respectively. Patients 3 and 4 presented with neonatal anaemia requiring regular transfusion and were diagnosed with Pyruvate Kinase deficiency. Deferasirox was started at 12 and 19 months consecutively. Patient 5 presented with pure red cell aplasia at the age of 3 months and was diagnosed with Diamond Blackfan anaemia. He was initially treated with steroid but became resistant at around 40 months of age. He was then started on regular transfusion and was started at deferasirox at 4 years of age. Patient 6 was diagnosed at birth with sickle cell anaemia. He suffered from stroke at the age of 8 months and was started on chronic transfusion program. Deferasirox was started at around at the age of 1. He had a successful maternal haplo-identical haemopoietic stem cell transplant at the age of 3 years old. Transfusion and deferasirox were subsequently stopped.

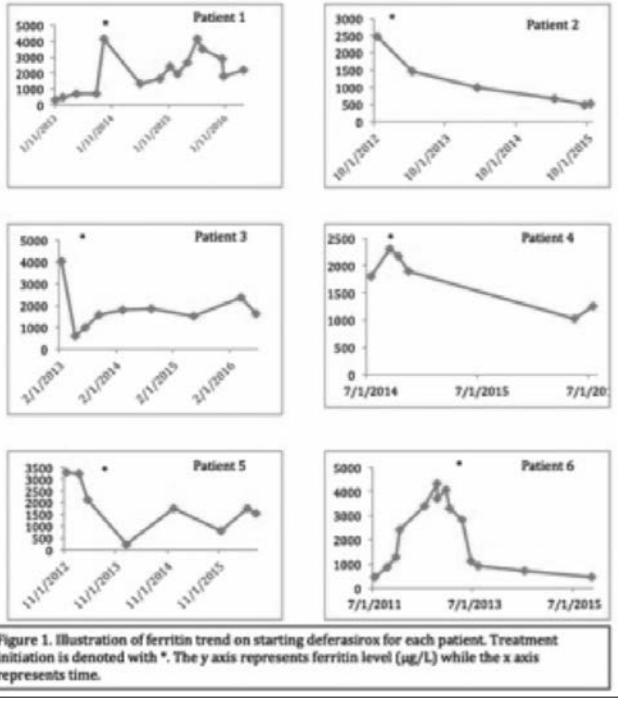

Figure 1. Illustration of ferritin trend on starting deferasirox for each patient. Treatment initiation is denoted with *. The y axis represents ferritin level (µg/L) while the x axis represents time.

Figure 1.

Summary/Conclusions: All of these children had stabilization or improvement of ferritin values after initiation of deferasirox as shown in figure 1. Deferasirox is licensed in Europe to be used in children with thalassaemia older than 6 years of age or older than 2 year of age when desferoxamine therapy is inappropriate or inadequate. Deferasirox is preferable in severe anemias due to better side effect profile on the bone marrow compared to deferiprone; the use of which can cause agranulocytosis or neutropaenia. Furthermore, its oral administration improved compliance compared to desferrioxamine that required prolonged subcutaneous administrations. Deferasirox has been associated with renal impairment. However, none of patients developed renal or liver impairment during the use of deferasirox. Furthermore, it is crucial to conduct eye and ear screening tests both before and after the commencement of deferasirox. None of our patients had neurological side effects. Three of these children had deferasirox started at younger than 2 years of age. Hence, we have shown that deferasirox is safe and efficacious in treating iron overload in very young children with rare anaemias and sickle cell disease where evidence is sparse.

E1164

MONITORING ORAL IRON THERAPY IN CHILDREN WITH IRON DEFICIENCY ANEMIA. AN OBSERVATIONAL, PROSPECTIVE, MULTICENTRIC STUDY

G. Russo[1,2,*], V. Guardabasso[3], P. Samperi[2], L. Lo Valvo[2], U. Ramenghi[4], R. Colombatti[5], M. Maruzzi[6], E. Facchini[7], S. Fasoli[8], F. Giona[9], D. Caselli[10], C. Pizzato[11], G. Boscarol[12], E. Bertoni[13], F. Tucci[14]
[1]Clinical and Experimental Medicine, University of Catania, [2]Pediatric Hemato-Oncology Unit, [3]Azienda Policlinico Vittorio Emanuele, Catania, [4]Department of Pediatric and Public Health Sciences, University of Torino, Torino, [5]Pediatric Hemato-Oncology Unit, University of Padova, Padova, [6]Pediatric Hemato-Oncology Unit, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, [7]Pediatric Hemato-Oncology Unit, Policlinico S.Orsola Malpighi, Bologna, [8]Pediatric Unit, Carlo Poma Hospital, Mantova, [9]Department of Cellular Biotechnologies and Hematology, "Sapienza" University, Roma, [10]Maria Paternò Arezzo Hospital, Ragusa, [11]Hospital, Treviso, [12]Central Teaching Hospital, Bolzano, [13]Spedali Civili, Brescia, [14]Ospedale Meyer, Firenze, Italy

Background: Iron deficiency anemia (IDA) is the most common hematological disease in infancy and childhood. Oral iron administration is a well-established, effective, and widely accepted treatment for anemia because of its efficacy, safety, and cost-effectiveness. Recently new preparations of oral iron compounds were launched, including droplet formulations, *i.e.* liposomal preparations and bis-glycinate iron; little is known on their effectiveness in real clinical practice.
Aims: To evaluate the efficiency of different oral iron preparations in children with IDA.
Methods: This observational study collected clinical and hematological data from 12 AIEOP (Associazione Italiana di Ematologia ed Oncologia Pediatrica) centers. Inclusion conditions for patient enrollment were age 3 months-12 years, diagnosis of IDA; exclusion criteria were all conditions interfering with iron absorption such as celiac disease, gastro-intestinal disorders and other chronic conditions. Local Physicians were free to prescribe any oral iron formulation, according to their standard practice. A calendar of laboratory test was suggested, including basal assessment of whole blood count, reticulocytes, iron status, with subsequent checkpoints at 3 days (WBC and retyculocytes only), 2 weeks, 8 weeks, 6 months. Clinical data regarding compliance to therapy, unwanted effects, final outcome were recorded.
Results: 112 (M 58) patients were enrolled. Ethnic distribution was: Caucasian 74, African 23, Asian 10, Other 5. The median age at diagnosis of IDA was 1.5 years, with a bimodal distribution with frequency peaks at age 0-3 and 12-14 years. Sixty-eight patients received bis-glycinate ferrous iron 0.45mg/kg, 19 elemental iron (ferrous gluconate/sulfate) 2mg/kg, 12 liposomal iron 0.7-1.4mg/kg, and 15 other preparations. Eating habits were reported as normal in 48 patients, inadequate weaning in 21, meat/fish restriction in 32, other in 11. Gastro-intestinal side effects were reported in 9/68 (13%) of the bis-glycinate iron group, in 3/19 (16%) of the elemental iron group, and in 0/12 of the liposomal iron group. Suspension of therapy due to side effects was needed only in 5 patients, 4 in the bis-glycinate and 1 in the elemental iron group, respectively. Final outcome was available for 77 patients; it was recorded as solved IDA, persistent IDA, or lost at follow up. Solved cases were 40/53 (75%) in the bis-glycinate iron group, 4/11 (36%) in the elemental iron group, and 8/13 (62%) in the liposomal iron group. Persistent cases were 8/53 (15%) in the bis-glycinate iron group, 6/11 (55%) in the elemental iron group, and 1/13 (8%) in the liposomal iron group. Lost at follow up were 5/53 (9%) in the bis-glycinate iron group, 1/11 (9%) in the elemental iron group and 4/13 (31%) in the liposomal iron group.
Summary/Conclusions: The collected data show that both bis-glycinate and liposomal iron formulations have a good efficacy/safety profile and offer a sustainable alternative to classic elemental iron preparations.

E1165

AN INVESTIGATION ABOUT WEIGHT GAIN WITH TREATMENT OF IRON DEFICIENCY ANEMIA: CHANGES OF GHRELIN AND HEPCIDIN LEVELS WITH TREATMENT

H. C. Kılınç[1], B. Onec[2,*], K. Onec[1], E. Caliskan[3], H. Ankaralı[4]
[1]Internal Medicine, [2]Hematology, [3]Medical Microbiology, [4]Biostatistics, Duzce University Faculty of Medicine, Duzce, Turkey

Background: Iron deficiency anemia (IDA) is a global health problem and problems in compliance with oral iron therapy are frequently seen. It has been shown that medications are not used regularly or discontinued due to weight gain during the treatment process.
Aims: We investigated ghrelin, known as appetite hormone and its relationship with hepcidin, the homeostatic regulator of intestinal iron absorption, in order to explain some symptoms of IDA and weight gain during iron treatment.
Methods: A hundred and twenty adult IDA patients, referred to our clinic between October 2015 and October 2016 were included in the study. The study was completed with 87 patients, who gave the informed content and a control group consisted of 50 healthy people. Information about age, gender, weight, height, body mass index (BMI), waist-hip circumference and blood samples were taken from the patient and control groups. The treatment of IDA was done according to the dose and method recommended by the responsible physician, the researchers did not have any effect on the treatment. Measurements and blood tests were repeated in the patient group after normalization of the anemia parameters, not before the third month of treatment. Hepcidin and ghrelin levels

were examined once in the control group and twice in the patient group, before and after treatment.
Results: When the patient and control groups were compared, there was no significant difference in terms of age, sex, height, weight, BMI, waist and hip circumference. The pretreatment plasma hepcidin and ghrelin levels of the patient group were significantly lower than those of the control group (80±21 ng/ml *vs* 179 ng/ml p <0.001 for hepcidine, 152±119 pq / ml *vs* 213±167 for ghrelin, p=0.026). There was a significant increase in terms of weight (mean 1.15 kg, p <0.001), BMI (25.86 kg/m^2 *vs* 26.33 kg/m^2, p <0.001), waist and hip circumference measurements (mean 0.81cm in both, p <0.001) after treatment in the patient group. After treatment, the levels of hepcidine was significantly increased compared to the pre-treatment levels (80±21 ng/dl *vs* 92±13 ng/dl, p<0.001). Although an increase in the plasma ghrelin levels was encountered after treatment, it was not statistically significant (152±119 pq/ml *vs* 164±150 pq/ml, p=0.589). When correlations of individual increases in ghrelin levels were examined, a weak positive correlation was found between increase in ghrelin levels and weight gain.
Summary/Conclusions: In our study, ghrelin was significantly lower than the control group in the IDA group, suggesting that it may be the cause of loss of appetite. Ghrelin is also detected in neurons of hypothalamic arcuat nucleus, which regulates appetite. The deficiency of iron may cause deficiencies in enzymatic activities of iron depended enzymes and it may disturb the function of these neurons. But the increase with treatment did not reach statistical significance. This may be due to physiological suppression of levels by weight gain. When patient-based weight gains were examined, there was a positive but weak correlation with the increase in ghrelin levels of those people. Hepcidin was significantly lower in the iron deficiency group than in the control group and showed a significant increase with treatment, but it was not associated with weight gain and change of ghrelin levels. More extensive and controlled studies should be designed in this regard.

SOMATIC MUTATION DYNAMICS IN HIGH-RISK MDS PATIENTS TREATED WITH AZACITIDINE IDENTIFIED VIA SERIAL SAMPLING

K. Polgarova[1], K. Vargova[2], V. Kulvait[2], N. Dusilkova[2], L. Minarik[1], Z. Zemanova[3], A. Jonasova[1], T. Stopka[1,2,*]
[1]Hematology Clinic, General Hospital, Prague, [2]Biocev, Charles University, Vestec, [3]Cytogenetic Center, General Hospital, Prague, Czech Republic

Background: Azacatidine (AZA) is a standard therapy for MDS patients with higher risk of AML transformation and not eligible to undergo transplantation. While AZA is well tolerated the responses occuring in upto two thirds of patients are not durable. Somatic mutations were previously associated with pathogenesis of MDS, some of them also with prognosis. Several studies suggested that MDS patients as they progress may evolve new mutations and loose some of the clonal architecture detected at preceding stages (Pellagatti, Roy *et al.* 2016). In addition, there exist gene mutations that are detected in patients subsequently responding to hypomethylating agents (Bejar, Lord *et al.* 2014), which implies that there exist variants-bearing clones that persist upon AZA as well as those that do not.
Aims: To identify variants either persisting or not upon the AZA therapy we tracked BM samples during AZA treatment. Next, we were interested in deciphering their relationship of the dynamics in somatic variants to clinical course of the analyzed MDS patients.
Methods: Massive parallel sequencing with high accuracy utilized duplicate libraries from myeloid cells and included the non- tumorous T-cell controls to identify somatic mutations in the serial samples before and during AZA therapy. The tool for detecting the dynamics of somatic mutations was the TruSight Myeloid Panel that contains 54 gene regions with previously documented mutation recurrence in 439 patients (Bejar, Stevenson *et al.* 2011). Indeed, 92% of our MDS cohort bore at least one somatic mutation with mostly 4 mutations per patient (range 1-9), which indicated that the MDS patients were already at relatively progressed state (Papaemmanuil, Gerstung *et al.* 2013).
Results: Analysis of 38 patients treated with AZA (reaching median OS 24 months (Mo) with 60% hematology improvement) revealed 125 somatic variants with VAF over 5%. Adverse effects of variants in cooperating regulators of DNA damage and cell cycle were confirmed: *TP53* (OS on AZA 14.8 Mo), *CDKN2A* (12.3 Mo), *EZH2* (11 Mo). Besides the stable variant's allele frequency (50%<VAF <200%) there existed four additional VAF profiles. Stable variants' dynamics precluded putative AZA-resistant clones associated with shorter survival (19 Mo). In contrast, the patients bearing variants with decreasing VAF, which supposedly were inhibited by AZA, lived longer (31 Mo). Interestingly, small group of highly dynamic variants upon AZA therapy formed a subgroup with longer-lasting complete remissions.
Summary/Conclusions: Our work support the importance of catalogization of somatic variants to delineate pathogenesis of MDS with a focus on molecular AZA responsiveness. Several types of variant dynamics during the AZA therapy were noted by using the massive parallel sequencing approach of the duplicate libraries per MDS BM samples also utilizing non-tumorous controls and serial sampling. Stable dynamics was found in variants previously recorded by COSMIC and targetting the adverse outcome genes such as *TP53*, *BCORL1*, *ASXL1*, and *EZH2* as well as their combinations with *TET2* that may potentially mediate clonal selection of additional variants mediating progression during AZA therapy.

E1167

WHOLE GENOME MBD-SEQ REVEALS DIFFERENT CPG METHYLATION PATTERNS IN AZACYTIDINE-TREATED JUVENILE MYELOMONOCYTIC LEUKEMIA (JMML) PATIENTS

P.P. Leoncini[1,*], P. Vitullo[1], F. Di Florio[1], V. Tocco[1], M.P. Cefalo[1], A. Pitisci[1], K. Girardi[1], C. Niemeyer[2], F. Locatelli[1], A. Bertaina[1]
[1]Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, [2]Pediatrics-Oncohematology, University of Freiburg, Freiburg, Germany

Background: Juvenile Myelomonocytic Leukemia (JMML) is a rare and aggressive leukemia of early childhood. Allogeneic hematopoietic stem cell transplant (HSCT) is the only available curative treatment, but, since disease recurrence is responsible for treatment failure in at least one third of transplanted patients, developing alternative therapeutic approaches is desirable. Aberrant DNA methylation is a key molecular feature of JMML, suggesting an important role of epigenetic events in the pathophysiology of the disease. Azacytidine (AZA), a molecule that inhibits DNA methylation in human cells, is under investigation in JMML.
Aims: Here we report, for the first time, a global evaluation of DNA methylation status of CD34$^+$ cells deriving from JMML patients before and after AZA treatment and compared the results with those of healthy controls. Identifying differentially methylated CpG islands linked to various genes will help us describe

an epigenetic aberrant paradigm possibly involving transcriptional and translational regulation in JMML.
Methods: CD34+ cells isolated from 3 JMML patients samples collected at diagnosis (t0) and after the third cycle of AZA (t1) were evaluated together with those of 3 healthy donors (HD). JMML patients have been treated with AZA on a compassionate use basis after obtaining signed informed consent. DNA samples were processed and Ion fragment libraries were prepared. MBD-seq, bioinformatics and statistical analysis were performed by Genomnia srl (Bresso, Italy).
Results: First, we compared t0 JMML cells with HD cells, finding 987 different transcriptional units corresponding to 714 coding and 273 non-coding sequences. We also compared DNA methylation between t1 and HD cells. In this comparison, 644 unique transcriptional units, including 468 coding and 175 non-coding sequences, were found. Hypermethylation in JMML samples compared to HD was detected, but, unexpectedly, t0 *vs* t1 methylation analysis did not show any significant result, suggesting a likely unspecific patient-related pharmacological effect. Notably, 453 coding and 165 non-coding differentially methylated regions are shared between t0 *vs* HD and t1 *vs* HD sets. More in detail, 261 and 15 coding regions and 107 and 10 non-coding regions were uniquely found in t0 *vs* HD and t1 *vs* HD sets, respectively. However, 439 coding and 161 non-coding genomic regions preserve their hypermethylated status, probably due to a mechanism of resistance to AZA treatment. Among non-coding elements, we found different RNA species, such as microRNAs, splicing RNAs, lincRNAs/antisense transcripts (AS) and other unknown RNAs. Retrotransposons, belonging to LINEs and SINEs families, were also screened. We identified 13 sequences with a significant differential methylation profile in both t0 and t1 *vs* HD. Again, a comparison between t0 and t1 groups did not show any significant difference. Eleven hypermethylated common LINEs were evident between t0 *vs* HD and t1 *vs* HD sets. Two retrotransposons with opposite methylation patterns were found in t0 *vs* HD and t1 *vs* HD sets; while in the first comparison they included LINEs, in the second one they are 1 hypermethylated LINE and 1 hypomethylated SINE.

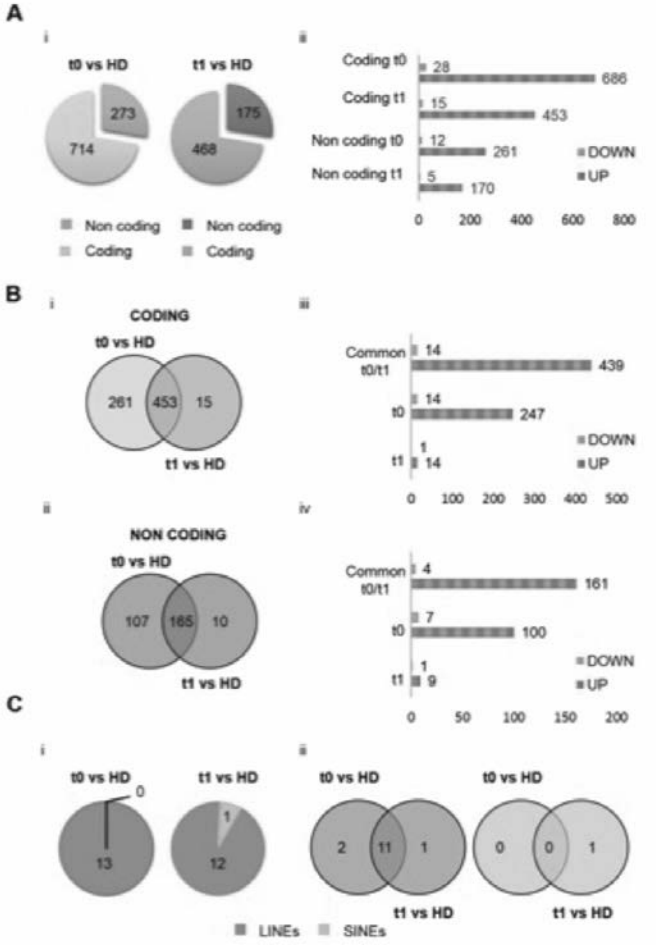

Figure 1.

Summary/Conclusions: In conclusion, the whole genome MBD-seq performed for the first time on JMML CD34+ bone marrow derived cells, showed a broad genomic hypermethylation both in pre- and post-AZA samples compared to HD, suggesting a patient-specific AZA-effect. Transcription and translation processes of coding and non-coding genes could be deregulated in multiple ways, due to heterogeneity of sequences involved in CpG islands hypermethylation. Moreover, due to their known ability to insert random mutations in the genome, retrotransposons should be candidate for further studies in JMML pathogenesis.

E1168

RESPONSE MONITORING IN MDS WITH DEL(5Q) USING DIFFERENT FLOW CYTOMETRIC (FCM)-SCORES IN COMPARISON TO CYTOGENETICS AN ELNET IMDS-FLOW EXPERIENCE

U. Oelschlaegel[1,*], T.M. Westers[2], B. Mohr[1], D. Subira[3], U. Johansson[4], G. Ehninger[1], M. Bornhäuser[1], A.A. van de Loosdrecht[2], U. Platzbecker[1]
[1]Medical Clinic and Policlinic I, MK1-L06, University Hospital of Tu Dresden, Dresden, Germany, [2]Department of Hematology, VU University Medical Center, Amsterdam, Netherlands, [3]Department of Hematology, Hospital Universitario de Guadalajara,, Guadalajara, Spain, [4]Department of Hematology, University Hospitals NHS Foundation Trust,, Bristol, United Kingdom

Background: Flow cytometry (FCM) is one part of integrated MDS diagnostics. Different well established FCM-scores are applied, as FCSS (Wells *et al.* 2003), Ogata-score (Ogata *et al.* 2012), new iFS (Cremers *et al.* 2017), and del(5q)-FCM-score (Oelschlaegel *et al.* 2015).
Aims: The aim of this prospective study was to test, which of the mentioned FCM-scores fits best for response monitoring in del(5q) MDS in comparison to cytogenetics.
Methods: Overall, 245 FCM investigations were performed in 61 patients with MDS and del(5q) (IPSS-R very low/low: n=26, int: n=13, high/very high n=22) including 42 patients with isolated del(5q) or one additional cytogenetic abnormality. The majority of analyses were performed in patients receiving lenalidomide or azacitidine (n=29 and n=22 patients), or in patients receiving chemotherapy and/or allogeneic transplantation or growth factors (n=10). Standardized FCM (lyse-stain-wash) and cytogenetics/FISH procedures were performed according to ELN guidelines at the TU of Dresden, VUMC of Amsterdam, UH of Guadalajara and UH of Bristol. Cytogenetics/FISH analysis was considered the gold standard. All of the applied FCM-scores were propagated by the ELNet iMDS working group. Additionally, hematological improvement of the erythroid lineage (HI-E) was evaluated (Cheson *et al.* 2006).
Results: The del(5q)-FCM-score reflected best the disappearance / presence of the cytogenetic abnormality del(5q) with a sensitivity of 98% and a specificity of 82%. This was confirmed if only MDS with del(5q) as a single abnormality or only MDS treated with Lenalidomide were evaluated separately (sensitivity: 98% and 100%; specificity: 85% and 75%). The use of the Ogata-score considering almost only abnormalities of the myeloid progenitors, ended up with a slightly lower sensitivity (86%) and specificity (81%). The new iFS analyzing progenitor cells, granulo-, mono-, and erythropoiesis showed a comparably high specificity (83%) but a slightly impaired sensitivity (72%). FCSS, analyzing dyspoiesis of multiple cell lineages, showed a response in less than the half of all investigations being in cytogenetic CR (sensitivity: 41%), but revealed a high specificity (91%). The analysis of HI-E was high sensitive (81%) but not as specific (62%). Next, we investigated the potential prognostic impact of response monitoring using various FCM-scores compared to cytogenetics. Considering all del(5q) MDS patients as well as only those patients with del(5q) as a single abnormality, cytogenetics and all tested FCM-scores showed a significantly longer OS for MDS responding to therapy. The highest prognostic impact displayed the new iFS (p=0.0019) and Ogata-score (p=0.0092), respectively. Evaluating only MDS treated with lenalidomide, response monitoring using FCSS separated best the OS curves (p=0.0080). Finally, we combined the evaluation of HI-E with cytogenetics or the FCM-scores. This resulted in an even better OS for MDS fulfilling two response criteria *vs* none of the criteria with the highest prognostic impact for the combination of HI-E plus the new iFS (p=0.0010).
Summary/Conclusions: Flow cytometry might serve as a rapid tool for response monitoring during treatment with disease-modifying drugs. All established FCM-scores allowed for an at least similar correctness of response prediction. The prognostic impact of the various FCM-scores seems to be even higher than that of cytogenetic response evaluation in this MDS subgroup. One reason might be, that most of the FCM-scores reflect not only the genetic background of the MDS but dyspoietic alterations in various cell lineages of the hematopoietic system.

E1169

EVALUATION OF MUTATIONS AT RELAPSE IN MYELODYSPLASTIC SYNDROME PATIENTS RECEIVING ALLOGENEIC STEM CELL TRANSPLANTATION

M. Cabrero[1,*], J.M. Hernandez-Sanchez[1], J.C. Caballero[1], C. Chillon[1], M. Martin-Izquierdo[1], M. Abaigar[1], A. Redondo[1], F. Lopez-Cadenas[1], E. Perez-Lopez[1], L. Lopez-Corral[1], R. Benito[1], C. Robledo[1], M. del Rey[1], M. Gonzalez[1], C. del Cañizo[1], D. Caballero[1], J.M. Hernandez-Rivas[1], M. Díez Campelo[1]
[1]Hematology Department, Hospital Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: Allogeneic transplant (AlloSCT) is the only curative therapy for myelodysplastic syndromes (MDS). Unfortunately, relapse is the main cause of treatment failure. Evaluation of genetic mutations both at diagnosis and

before AlloSCT is a potent prognostic tool. However, mutational profile at relapse after AlloSCT has not been widely explored.
Aims: In this study, we evaluate mutational profile at post-AlloSCT relapse in MDS patients to determine if pre-AlloSCT mutations are still present at relapse, so we could eventually monitor them as minimal residual disease (MRD) after AlloSCT.
Methods: From a retrospective cohort of 115 patients, we selected those who relapsed post-AlloSCT (19/115, 16.5%) with available material at relapse (18 patients). We performed an in-house target-capture panel, sequencing across selected exons of 117 cancer-related genes previously related to MDS in pre-AlloSCT samples to identify genetic mutations and we checked the presence of those mutations in samples at relapse. Six patients were discarded because lack of pre-AlloSCT mutations, so we selected 12 patients for the sequential study. DNA was amplified with FastStart High Fidelity PCR System using exon-specific primers for each mutation. The indexed paired-end library was prepared with Nextera XT DNA Sample Preparation Kit (Illumina) The median coverage per base achieved was 4579 reads range 2401-8573). In a second step, we explore the possibility of evaluating mutations in both CD34 positive and the rest of bone marrow cells, to check if we could increase the sensitivity of the detection.
Results: Median age of relapsed patients was 60 (45-70). Diagnosis were RAEB 1 (n=4), RAEB 2 (4), dysplasia associated AML (2) and RCMD (2). They relapse post-AlloSCT after a median of 2.5 months (1-7), and 4 of them are alive at last follow up after a median of 22 months (9-33). Patients had a median of 2.5 mutations (range 1-4). TET2 mutations were detected in 4 (33%) of patients; U2AF1, EZH2, SRSF2, KRAS, JAK2 and RUNX1 in 2 (17%), and NRAS, TP53, ETV6, PHF6, SMC1A, ZRSR2, BCOR, DNMT3 and SF3B1 mutations in 1 (8%) (Table 1). In 10 out of 12 patients evaluated, we found same genetic mutations at relapse compared with pre-AlloSCT sample (Table 1). In addition, mutational pattern was similar for all patients except for one in which dominate mutation at relapse was SRSF2 (present in 14% of cells pre-Allo and in 3% at relapse) instead of ETV6 (51% pre-AlloSCT and 0.6% at relapse). In 2 patients, pre-AlloSCT mutations were not detected at relapse (Patient 8: BCOR and RUNX1. Patient 11: SRSF2, TET2 and RUNX1). In a second step, we searched for mutations in CD34 positive cells to check its sensitivity to detect genetic alterations. We selected CD34 positive cells in one patient with KRAS and IDH2 mutations pre-AlloSCT. KRAS and IDH2 were present in 40% and 45% of CD34 positive cells and in 37% and 48% of the bone marrow (CD34 depleted) compartment respectively in pre-AlloSCT samples. In relapse samples, mutations were present in similar percentage in CD34 positive cells compared to CD34 depleted bone marrow (KRAS 0.63% and 2.23%; IDH2 1.6% and 1.45% respectively).

Summary/Conclusions: Post-AlloSCT relapsing MDS show same genetic mutations found in pre-AlloSCT evaluation, so they would potentially be used to confirm clonality and probably MRD assessment after AlloSCT in the near future. CD34 selection does not provide additional sensitivity to whole bone marrow cellularity sample.

E1170

RIGOSERTIB COMBINED WITH AZACITIDINE EPIGENETICALLY MODULATES CHROMATIN AND HEMATOPOIETIC STEM CELL POPULATIONS IN THE MYELODYSPLASTIC SYNDROME (MDS)

P. Chaurasia[1], S.C. Navada[1], R. Odchimar-Reissig[1], E.P. Demakos[1], P. Reddy[1], L.R. Silverman[1,*]
[1]ICAHN School of Medicine, Mount Sinai, New York, United States

Background: Azacitidine (AZA) is the standard of care for patients (pts) with higher-risk MDS, however, only 50% of pts respond and the majority will relapse within 2 years. All pts ultimately fail treatment due to primary or secondary resistance. RIGosertib (RIG) is a "ras mimetic" agent that binds to the Ras Binding Domain of RAF kinases and inhibits the RAS-RAF-MEK and the PI3K pathways. Initial results of an ongoing Phase I/II study with RIG combined with AZA, in pts with MDS demonstrated a response rate of: 76% overall; 62% in pts following hypomethylating agent (HMA) failure and 85% in HMA naïve pts (Navada et al ASH 2016).
Aims: To Investigate the *in vitro* effects of RIG combined with AZA or vorinostat (VOR) on epigenetic and stem cell pathways on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples
Methods: We investigated the *in vitro* effects of RIG combined with AZA or vorinostat (VOR) on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples treated on the phase I/II study, obtained prior to and after one cycle of AZA and RIG.
Results: Treatment with RIG alone altered global histone post-translational modifications (PTMs) including methylation (H3K4me3, H3K4me2, H3K27me3, and H3K27me2) and acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both the cell lines and pt samples. Q-PCR studies demonstrated that individual treatment of BW90 and MDS-L with RIG or combined with AZA or VOR in sequential treatment (AZA/RIG, RIG/AZA, VOR/RIG or RIG/VOR) altered DNA methyl transferases (DNMT1, 3a and 3b), the class I, II and IV histone deacetylases (HDACs), and chromatin remodeler (KDM2a, SET1, JMJD3 and LRWD1) transcript levels in a cell line specific context. Sequential treatment of RIG with AZA or VOR demonstrated differential effects on the association of RNA polymerase II (Pol II) with active histone marks (H3K4me3 and H3K4me2) in both cell lines. An overall decrease in association of Pol II/H3K4me2 was observed with the combinations (AZA/RIG, VOR/RIG or vice versa) in MDS-L and BW-90, 10-33% (ANOVA, p=0.0006), 9-20% (ANOVA, p=0.0004), respectively. Significant differences were observed in association of H3K4me3/Pol II in BW-90 cells (7-30%; ANOVA, p<0.0001). Similarly, in BM from a pt with MDS after 1 cycle of RIG and AZA treatment demonstrated a decrease in association of Pol II with H3K4me2 (67%) and H3K4me3 (28%). Treatment of MDS-L cells with RIG alone or RIG/AZA failed to induce expansion of $CD34^+$ cells and yielded maximum aldehyde dehydrogenase (ALDH) activity, a marker of primitive hematopoietic stem and progenitor cells (HSCs) (ANOVA, p=0.006), but the RIG/VOR induced 1.9-fold expansion of $CD34^+$ cells (ANOVA p=0.002). A marked decrease in ALDH activity was observed in AZA or VOR or RIG/VOR, that was inversely proportion to the expansion of $CD34^+$ cells. In an MDS pt treated with RIG/AZA an expansion of primitive HPSCs expressing low levels of CD34 appeared with disappearance of a highly expressing CD34 subpopulation that co-existed prior to treatment. Expansion of $CD34^+$ cells led to ≥2 fold increase in pluripotent genes (SOX2, OCT4, NANOG and ZIC3) expression levels in the BM from MDS pts after RIG/AZA treatment and 1.7-34 fold increase in the presence of RIG or RIG/AZA or RIG/VOR in MDS-L. These findings indicate that expression of pluripotency genes is a consequence of epigenetic reprogramming that favors expansion of more primitive HSPCs in a pt.
Summary/Conclusions: RIG potentially functions as a chromatin modifying agent, in combination with AZA and may overcome HMA resistance through chromatin remodeling. RIG alone and in combinations also leads to epigenetic reprogramming of HSPC that may manifest in hematological improvements in the clinical setting.

E1171

UNEXPLAINED CYTOPENIAS IN HOSPITAL: INDICATIONS AND BENEFITS OF NEXT-GENERATION SEQUENCING

D. Beauvais[1,*], B. Céline[1,2], O. Nibourel[2,3], C. Preudhomme[2,3]
[1]Department of Adult Hematology, CHRU University Hospital of Lille, [2]UMR-S 1172, Institute for Cancer Research of Lille, [3]Biology and pathology center, Laboratory of Hematology, CHRU University Hospital of Lille, Lille, France

Background: Unexplained cytopenias (UC) are common problems during hospitalisation, particulary in elderly patients. If there is no evident cause, myelodysplastic syndrom (MDS) is frequently suggested and a bone marrow aspiration is performed. Next-generation sequencing (NGS) reveals MDS-associated somatic mutations but their significance are discussed. In our centre, NGS was systematically realized in the context of unexplained cytopenias.
Aims: The objective of this study was to explore results of NGS in practical routine in the context of UC and to precise if some groups of patients could more specifically benefit of NGS.
Methods: All patients in our centre with analysis of NGS performed in blood or in bone marrow in a context of UF were included. Exclusion criteria were: patients under 18 years, monocytosis >1000/mm^3, excess of blasts, history of hematological malignancy disorder. Patients were included in group "positive NGS" if at least one significant mutation (no SNP) was found on 25 genes panel (ASXL1, CBL, DNMT3A, ETV6, EZH2, IDH1, IDH2, JAK2, KIT, KRAS, MPL, NPM1, NRAS, PHF6, PTN11, RIT1, RUNX1, STBP1, SF3B1, SRSF2, TET2, TP53, U2AF, WT1, ZRSR2). Clinical and biological criteria were reported from local database. All patients gave consent.

Results: 156 patients were included between January 2014 and December 2015 with a mean age of 68 years [65.8-70.3] and 47.4% of men. 127 patients (81.4%) had a bone marrow analysis. 53 patients (34.0%) were reported in the group "positive NGS" and 103 patients (66.0%) in the group "negative NGS". In univariate analysis, significant variable associated with "positive NGS" were age (p <10-7), no history of auto-immune disease (p=0.002), hemoglobin <12g/dL (p=0.017), platelets >150000/mm^3 (p=0.015), >10% dysplastic cells in erythroid (p=0.012) and granulocytic lineage (p=0.034). Trend test on dysplastic lineage number was significant (p=0.006). Normal karyotype (78.1%) was comparable in the two groups (p=0.352). Cirrhosis and/or portal hypertension were comparable in the two groups (14.1%, p=0.092) as well as mean serum creatinine (p=0.24). In multivariate analysis, age >70 years (p=0.0011) and platelets >150000/mm^3 (p=0.0213) remained significantly associated to positive NGS (Table 1). In "positive NGS" group, 1 (58.5%), 2 (32.1%), 3 (7.5%) or 4 (1.9%) mutation(s) were found per patient. Most frequent mutations were TET2 (25.9%), DNMT3A (17.3%), SF3B1 (12.3%), ASXL1 (12.3%), SRSF2 (8,6%), U2AF1 (4,9%), TP53 (3,7%) and ZRSR2 (3,7%). Other mutations were reported in less than 3 patients. As expected in this elderly population, if a unique mutation was found, TET2 and DNMT3A were predominant (35.5% and 25.8% respectively) but interestingly mutation R882 of DNMT3A was found in only one patient. Sideroblasts were found>15% in 46.2% of patients with a mutation of SF3B1, SRSF2, U2AF1 or ZRSR2.

Table 1.

Table 1. Clinical and biological characteristics, univariate analysis. Variables with p<0.20 were included in multivariate analysis. Age > 70 years (p=0.0011) and platelets > 150000/mm3 (p=0.0213) remains significantly associated to positive NGS in multivariate analysis.

Summary/Conclusions: In the context of unexplained cytopenias, a third of patients had at least one MDS-associated somatic mutation. Age above 70 years and no thrombopenia seems to be good arguments to realize NGS in this context. Probably thrombopenia is frequently associated to other causes than MDS. If NGS is positive, aging genes are the most frequently mutated genes and they can reflect age-related clonal cytopenias. Even if their clinical significance is uncertain, monitoring is recommended because of an increased risk of hematologic cancer.

RESISTANCE TO AZACITIDINE IS DETERMINED AT CELLULAR LEVEL BY LOWER EXPRESSION OF NUCLEOSIDE ACTIVATING ENZYMES UCK1 AND UCK2

E. Masala[1,*], A. Valencia[1], A. Brogi[1], A. Sanna[1], M. Torres Martin[2], M. Figueroa[2], V. Santini[1]
[1]Experimental and Clinical Medicine, University of Florence, Florence, Italy, [2]Department of Human Genetics, University of Miami Miller School of Medicine, Miami, United States

Background: Azacitidine is at present the standard treatment for MDS. We demonstrated that MDS patients responsive to azacitidine have significantly higher intracellular expression of the azacitidine-activating enzyme uridine-cytidine kinase-1 (UCK1) in bone marrow mononuclear cells (Valencia *et al.* Leukemia 2014). Correlation of the expression of nucleoside transporter, activating and disactivating enzymes with clinical and *in vitro* response to hypomethylating drugs azacitidine and decitabine has been suggested by several authors. Yet, the crucial role of these enzymes has to be ascertained, as well as their possible different importance in determining resistance to azacitidine.

Aims: To confirm that the cellular expression of nucleoside metabolizing enzymes plays a major role in cellular resistance and significantly impacts on clinical response to azacitidine.
Methods: Two cell lines, SKM1 sensitive (SKM1-S) and SKM1 resistant (SKM1-R) to azacitidine, were analyzed for expression of *UCK1, UCK2, hENT1, hCNT3, RRM1* and *RRM2* by quantitative PCR. Corresponding proteins were quantitated by western blotting in both cell lines. The expression of *UCK1* and *UCK2* was blunted by siRNAs in SKM1 sensitive cells to determine their role in *in vitro* sensitivity to azacitidine. For UCK1 and UCK2 silencing in SKM1-S, specific siRNAs were used (OriGene Technologies, MD, USA); cells were cultured at a density of 600x10^{5}cells/ml in 5 ml of RPMI 1940 medium. After 72 h of transfection, cells were treated for further 48h with azacitidine at the concentrations of 0,1 and 1 μM. After assessment of effective gene silencing, apoptosis and cell cycle arrest were evaluated, respectively by Annexin V test and Propidium Iodide. In parallel, the percentage of 5-methylcytosine was quantitated by ELISA assay (Global DNA Methylation LINE-1 kit ActiveMotif, CA, USA). In addition, the expression of nucleoside metabolizing enzymes was evaluated prospectively in 18 IPSS high risk MDS patients treated with azacitidine 75mg/m^2/7 days every 28 days. Furthermore, UCK1 and UCK2 expression was evaluated in 37 patients (classified as 26 responder and 29 non-responder) treated with azacitidine, by RNAseq analysis using DEXseq2.
Results: SKM1-R cells did not express *UCK1, UCK2, hENT1, hCNT3*, *RRM1* and *RRM2*. Corresponding proteins were also not expressed. A reduction of apoptosis was observed in *UCK1*-silenced SKM-1 S after azacitidine 0.1 μM treatment: 35,7%±0,77% Annexine V-positive cells *versus* 25%±0,35% (*P*=0.031) in non-silenced control SKM1-S cultures. We observed a reduction of apoptosis during *UCK2*-silencing after azacitidine 0.1 μM treatment too: 31%±0,85% Annexin V-positive cells *versus* 21%±0,35% (*P*=0.054). Hypomethylation induced by *in vitro* azacitidine treatment was also hampered by reduction of expression of *UCK1 and UCK2*. Quite surprisingly gene expression of *UCK1, UCK2, hENT1, hCNT3*, *RRM1* and *RRM2* in primary cells did not predict different clinical response to azacitidine. RNAseq analysis for UCK1 and UCK2 did not find any differences between responder and non-responder patients.
Summary/Conclusions: We demonstrated that *UCK1, UCK2, hENT1, hCNT3*, *RRM1* and *RRM2* and the corresponding proteins are absent in azacitidine-resistant cell line SKM1-R suggesting to be the determinant of the induced resistance to azacitidine. *UCK1 and UCK2* silencing induced by synthetic siRNAs significantly decreased azacitidine effects. Prospective evaluation of the predictive role of cellular expression of genes involved in azacitidine metabolism is ongoing in a larger cohort of MDS patients.

FAMILIAL TIN2 N-TERMINAL LOSS OF FUNCTION MUTATION IN TELOMERE SYNDROME

D. Di Giacomo[1,*], V. Nofrini[1], T. Iannotti[1], M. Quintini[1], F. Pellanera[1], G. Barba[1], C. Matteucci[1], S. Ballanti[1], R. Piazza[2], C. Mecucci[1]
[1]Haematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, [2]Medicine and Surgery, University of Milano-Bicocca, Milan, Italy

Background: The shelterin complex protects telomeres from being processed by the DNA damage repair machinery and regulates telomerase access and activity (Frank 2015). *TINF2* (14q12) is encoding for TIN2, the central component of shelterin which interacts with other members of the complex (TRF1,TRF2 and TPP1), thus contributing to telomere length regulation and structural integrity (Frank 2015). About thirty *TINF2* mutations are known in Dyskeratosis Congenita (DC) (Savage 2008) and other telomere related phenotypes, *i.e.* aplastic anemia (AA), idiopathic pulmonary fibrosis, liver cirrhosis, myelodysplastic syndromes (MDS) and acute myeloid leukemia (Armanios 2012). All mutations were missense and heterozygous, clustering in exon 6 encoding for a highly conserved segment at the C-terminus (aa 280–291) (Frank 2015).
Aims: Precise diagnosis in AA/MDS with clinical features of telomere syndrome.
Methods: AA was diagnosed in a 69-year-old man, with a multisystem disorder, *i.e.* psoriasis, nail dystrophy, severe osteoporosis, chronic hepatopathy, mild chronic kidney failure and hypertension, suggesting a telomere syndrome. Karyotype was normal. Patient was unresponsive to immune-suppressive therapy. DNA from peripheral blood and hair bulbs was analyzed for *TERT*, *TERC* and *TINF2* using DHPLC and Sanger sequencing. Q-FISH investigated telomere length. SNPs were performed following manifacturer's instructions (Affymetrix). Paired-end libraries for Whole Exome Sequencing (WES) were generated with NimbleGen Exome Capture v3 (Roche), according to manufacturer. DNA from CD3+ population was used for germinal matching. Data were aligned to the human reference genome (GRCh38/hg38) and analyzed with the in-house CEQer2 software (Piazza 2013). Mutational analysis and telotype were performed in both proband and familial members. *TERF2* and *TINF2* coding sequences were cloned in pGem-Teasy vector and site direct mutagenesis reproduced *in vitro* the mutation. Using expression vectors, respectively pEGFP-C1 and pDsRed-Express-C1, TRF2 and TIN2 wild type or TRF2 and TIN2 mutated were co-expressed in HEK-293T cell line. Co-immunoprecipitation was performed with anti-GFP antibody and differences in TRF2 binding between TIN2wt and TIN2mut were revealed by western blotting.

Results: A new *TINF2* germinal variation at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healty donors was negative. Significantly short telomeres were found in proband (p=0,0161) and brothers (p=0.0082 and p<0,0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in *TLR1* gene (c. 1859G>A, p.R620Q). Co-immunoprecipitation experiments showed that the new *TINF2* mutation reduced TIN2 binding with TRF2 *in vitro*.
Summary/Conclusions: A new *TINF2* germinal variation at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healty donors was negative. Significantly short telomeres were found in proband (p=0,0161) and brothers (p=0.0082 and p<0,0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in *TLR1* gene (c. 1859G>A, p.R620Q). Co-immunoprecipitation experiments showed that the new *TINF2* mutation reduced TIN2 binding with TRF2 *in vitro*.

FUNCTIONAL EXPRESSION OF TIM-3 AND CLINICAL SIGNIFICANCE OF PLASMA GALECTIN-9 LEVELS IN MYELODYSPLASTIC SYNDROMES

T. Asayama[1,*], M. Ishibashi[1], H. Tamura[1], Y. Kuribayashi-Hamada[1], N. Takada-Okuyama[1], A. Onodera-Kondo[1], K. Moriya[1], N. Yokose[2], K. Inokuchi[1]
[1]Division of hematology, Department of medicine, Nippon Medical School, Tokyo, [2]Division of hematology, Department of internal medicine, Chiba Hokusoh Hospital, Chiba, Japan

Background: T-cell immunoglobulin and mucin domain-3 (Tim-3) is an inhibitory immune checkpoint molecule that suppresses adaptive immunity by binding with galectin-9 (gal-9). The Tim-3−gal-9 pathway is associated with self-renewal of leukemic stem cells in acute myeloid leukemia (AML), although the function of the axis in myelodysplastic syndromes (MDS) remains unclear.
Aims: To clarify the expression and function of Tim-3 and clinical impact of its ligand gal-9 in MDS.
Methods: 1) We evaluated Tim-3 expression on CD45-gating blasts of bone marrow mononuclear cells (BMMCs) in 20 patients with MDS and AML transformed from MDS (AL-MDS), 12 healthy controls, and 4 MDS cell lines using flow cytometry (FCM). 2) To investigate Tim-3 induction, MDS cell line F-36P cells were co-cultured with the culture supernatant of human stromal cells and MDS-related cytokines. 3) To elucidate the functions of Tim-3 on MDS cells, F-36P cells were divided into Tim-3$^+$ and Tim-3$^-$ fractions with FACS sorting and their differential gene expression was determined with oligonucleotide microarray analysis. 4) To investigate the proliferative potential of Tim-3 signaling, intracellular Ki-67 expression in F-36P cells was evaluated using FCM when co-cultured with/without anti-Tim-3 blocking antibody. 5) Finally, we analyzed gal-9 concentrations in cell culture supernatants of MDS cell lines and in plasma obtained from patients with MDS (n=51) and AL-MDS (n=19), and healthy donors (n=10) using ELISA.
Results: 1) Tim-3 expression was observed on monocytes and CD45-gating blasts in MDS BMMCs and in all 4 MDS cell lines. In AL-MDS patients, Tim-3 expression levels on blasts were markedly higher than in controls and MDS patients. 2) Tim-3 expression in F-36P cells was increased by co-culture with the culture supernatant of human stromal cells and the MDS-related cytokine transforming growth factor-β1 (TGF-β1). Tim-3 cell-surface protein and mRNA expression in MDS cell lines was induced by co-culture with TGF-β1. The Tim-3 induction was abrogated by adding the TGF-β receptor I kinase inhibitor SD208. 3) Microarray analysis showed 572 upregulated genes (>2-fold difference) and 304 downregulated genes (<0.5-fold difference) in Tim-3$^+$ F-36P cells compared with Tim-3$^-$ cells, and ingenuity pathway analysis of those genes revealed upregulation associated with cell proliferation and antiapoptotic responses in Tim-3$^+$ cells. 4) The blockade by anti-Tim-3 antibody decreased intracellular Ki-67 expression in F-36P cells, suggesting that Tim-3 signaling induced MDS cell proliferation. 5) Soluble gal-9 was detected in culture supernatants of MDS cell lines and PBMCs obtained from AL-MDS patients. Soluble gal-9 levels and gal-9 mRNA expression were upregulated by MDS-related cytokines interferon-γ and tumor necrosis factor-α. Plasma gal-9 levels were higher in MDS and AL-MDS patients than in healthy controls (P<0.0001). When MDS patients were divided into high (defined as >10 ng/mL) and low (≤10ng/mL) gal-9 groups, the high group had poorer overall survival compared with the low group (P=0.001), even in refractory anemia (RA)/RA with ringed sideroblast patients alone (P=0.0029). Multivariate analysis revealed that a high gal-9 level was an independent poor prognostic factor (P=0.0017).
Summary/Conclusions: Our data suggest that Tim-3 expression and plasma gal-9 levels were upregulated in advanced-stage MDS. Tim-3 is associated with cell proliferation of MDS blasts, and higher plasma gal-9 is a poor prognostic marker in MDS. These molecules could play a key role in MDS disease progression.

PROGNOSTIC SIGNIFICANCE OF GENE MUTATIONS IN MDS DEPENDS ON THE LOCI OF GENE VARIANCES

T. Boneva[1,*], L. Rai[1], D. Brazma[1], R. Dunn[1], C. Grace[1], E. Nacheva[1,2]
[1]OncoGenomics, HSL Analytics LLP, [2]Cancer Institute, UCL, LONDON, United Kingdom

Background: Myelodysplastic syndromes are a collection of clonal hematopoietic disorders with a wide range of clinical manifestations and eventual outcomes. Predicting the prognosis is of great importance for defining the risk and select treatment options. Several models of risk stratification exist, all of which include genetic markers along with other clinical and paraclinical features. The Revised International Prognostic Scoring System (IPSS-R, *Greenberg et al., Blood. 2012;120(12): 2454-2465)* defines 5 risk levels based on the presence of specific chromosome abnormalities. These genome aberrations provide evidence for disease although reports of frequent driver mutations (*Papemauilie et al., Blood, 2013)* and/or structural variants detected by single nucleotide polymorphism (SNP) arrays (*Tiu et al., Blood, 2011*) have shown a potential for score criteria in the diagnosis of MDS. Recent reports of the presence such genetic aberrations in disease free individuals makes this approach problematic (*Genovese et al., N Engl J Med 2014; Lichman, Blood 2015, Kwok et al., Blood 2015*). A study of patients without evidence for MDS identified a driver mutation and/or structural gene variants in 91% of pre-diagnostic samples with the mutational spectrum mirroring that seen in MDS population (*Cargo et al. Blood, 2015*). The presence of mutations with greater median variant allele fraction (40% *vs* 9% to 10% in healthy individuals) and occurring with additional mutations (>2 mutations, 64% *vs* 8%) were shown to define a high-risk group with a shorter time to disease progression and poorer overall survival.
Aims: To compare the genomic profile of bone marrow from 145 adults, 76 of whom met the WHO criteria for MDS.
Methods: All samples were screened by chromosome G banding or molecular karyotyping using 8x60K oligonucleoitiude arrays (Agilent, USA) or screened by FISH using probes (Cytocell, UK) targeting the most common aberrations associated with MDS as per IPSS-R classification (Greenberg et al., Blood, 2013). The commercially available target gene panel TruSight on a MiSeq platform (Illumina, USA) was used to screen mutational hotspots in 54 cancer-related genes relevant in myeloid malignancy. Gene variances were reported at allele frequencies (VAF) >10% and at minimum read depth of 300 as per manufacturers criteria. We used the Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (>2%) to classify gene variants as either drivers, variants of unknown significance and germline polymorphisms (SNPs).
Results: A total of 145 bone marrow samples from 58 women and 87 men, aged from 26 to 85 suspected to have myeloid dysplasia were investigated. Of these only 76 (52%) were found to fulfill the WHO, criteria referred to as MDS positive, the rest as MDS negative. Gene variances were detected in all but 7 samples (5%). The latter appear to be void of gene mutations. We observed driver mutations as reported in myeloid malignancies in 68 (47%) samples whilst 70 (48%) were found to carry the same variances seen in disease free individuals or of unknown significance. As expected driver variances were not identified in any of the samples that failed the WHO criteria for MDS. Variances were detected in all samples for 35 of the 54 genes targeted by the TruSight myeloid panel. In order of frequency these are TET2, SRSF2, ASXL1, CUX1, DNMT3A, RUNX1, BCORL1 and HRAS, seen in more that 10% of all samples, while the rest were less frequently reported. The aberrant genes ASXL1, TET2 and SRSF2 figured prominently in both groups of samples with comparable frequencies as may be expected from published data and there were in addition a number of aberrant genes unique to the MDS group albeit at low frequency. When we examined the distribution of individual variances (rather than genes) we found a number of unique loci of the genes ASXL at 131022441, U2AF at 144524456 and TET2 at 106197285 to be associated with the MDS positive group. A more detailed analysis on the significance of these findings will be presented.
Summary/Conclusions: We compared 145 bone marrow samples from patents presenting with MDS of which 76 met the WHO criteria. There is little difference in their genomic profile when comparing the two groups on the basis of the most highly involved genes (ASXL1, TET2 and SRSF2) but if we compare the two groups by variance, 9 variances are exclusively associated with MDS positive disease.

E1177

SUPPRESSION OF DNA METHYLTRANSFERASE ENZYMES BY A NOVEL HYPOMETHYLATING AGENT, SGI-1027, IN AZACITIDINE- AND DECITABINE-RESISTANT CELL LINES

E.-H. Hur[1,*], D.R. Choi[2], B.-K. Goo[1], J.H. Moon[1], E.-J. Choi[1], H.-S. Park [1], J.-H. Lee[1], K.-H. Lee[1], J.-H. Lee[1]
[1]Hematology, Asan Medical Center, University of Ulsan College of Medicine, SEOUL, [2]Internal Medicine,, Chuncheon Sacred Heart Hospital, Hallym University College of Medicine, Chuncheon, Korea, Republic Of

Background: We established azacitidine- and decitabine-resistant cell lines, MOLM/AZA-1 and MOLM/DEC-5 from MOLM-13, an acute myeloid leukemia cell line (*Oncotarget* in press). DNA methyltransferase (DNMT) 3B was upregulated in the resistant cell lines.
Aims: We tried to find out clues to overcome the resistance to hypomethylating agent (HMA).

Methods: Besides azacitidine and decitabine, three other agents (SGI-1027, zebularine, and gemcitabine) are known as having hypomethylating effect. *in vitro* activities of the 5 HMA's on HMA resistant cell lines (MOLM/AZA-1 and MOLM/DEC-5) were tested by cell viability assay using luminescent-based CellTiter-Glo system. Protein and mRNA levels of DNMT enzymes (1, 3A, and 3B) were assayed before and after treatment of each HMA. Proteosomal degradation and activation of Akt were also determined to see the correlation with changes of DNMT's.
Results: Although azacitidine and decitabine could suppress DNMT1 and DNMT3A in MOLM-13, the agents could not suppress DNMT enzymes in resistant cell lines. Inhibition of proteosomal degradation by bortezomib induced accumulation of DNMT enzymes in MOLM-13, whereas it did not accumulate the enzymes in MOLM/AZA-1 and MOLM/DEC-5. Phosphorylated Akt (p-Akt) was dramatically overexpressed in MOLM/AZA-1 and MOLM/DEC-5. SGI-1027 showed the lowest IC_{50} values for MOLM/AZA-1 and MOLM/DEC-5, and it suppressed the protein levels of all three DNMT enzymes. SGI-1027 could also decrease the level of p-Akt. GDC-0941, a PI3K inhibitor, suppressed DNMT1 and DNMT3A as well as p-Akt, but it could not decrease DNMT3B in MOLM/AZA-1 and MOLM/DEC-5. Cell viability assay showed the synergistic effects of combination of GDC-0941 and Nanaomycin A, a specific DNMT3B inhibitor, in MOLM/AZA-1 and MOLM/DEC-5.
Summary/Conclusions: DNMT levels of MOLM/AZA-1 and MOLM/DEC-5 were not dependent on proteosomal degradation. DNMT1 and DNMT3A might be regulated via PI3K-Akt pathway, while regulation of DNMT3B might be different from DNMT1 and DNMT3A. SGI-1027 appears to exert inhibitory effects on MOLM/AZA-1 and MOLM/DEC-5 by inhibition of both p-Akt and DNMT3B.

MECHANISTIC HIGHLIGHTS OF IMPROVED ERYTHROPOIESIS WITH A LOW DOSE OF DEFERASIROX IN LOW RISK MYELODYSPLASTIC SYNDROMES

M. Mathieu[1,2,*], S. Ancelet[2], C. Lefebvre[3], J. Arnaud[4], C. Garrel[4], M. Pezet[5], Y. Wang[2], P. Faure[4], G. Szymanski[3], B. Polack[3], J. Y. Cahn[12], J. M. Moulis[6,7,8], S. Park[1,2]
[1]Clinique Universitaire d'hématologie, CHU Grenoble Alpes, [2]Equipe TheREx-laboratoire TIMC, Université Grenoble Alpes, [3]Laboratory of hematology, [4]Unité de Biochimie Hormonale et Nutritionnelle, Département de Biologie - Toxicologie - pharmacologie, CHU Grenoble Alpes, [5]Plateforme de Microscopie Photonique - Cytométrie en Flux, Institut Albert Bonniot, Université Grenoble Alpes, [6]LBFA, Inserm U1055, [7]CEA-Grenoble, Bioscience and Biotechnology Institute, [8]Laboratory of Fundamental and Applied Bioenergetics, and Environmental and Systems Biology, Université Grenoble Alpes, Grenoble, France

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous clonal stem cell disorders leading to ineffective hematopoiesis. Anemia is a frequent cytopenia in MDS and the majority of patients requires red blood cell (RBC) transfusion resulting in the development of iron overload (IO). Deferasirox (DFX) became a standard treatment of IO in MDS and seems to have positive effects on hematopoiesis with a reduced need of RBC transfusion.
Aims: Decipher the mechanisms of the potential improvement of erythropoiesis with DFX.
Methods: We report our *in vitro* data about the proliferation, cell cycle, apoptosis, erythroid differentiation, and cell signaling pathways concerning $CD34^+$ hematopoietic stem progenitor cells from low risk MDS samples in a 2-step erythroid differentiation liquid culture with low dose DFX and iron overload.
Results: We observed a higher proliferation rate for cultures with 3µM DFX *versus* the control condition (p=0.038). In contrast, no increased proliferation was found with DFX>5µM and with other chelators used in the clinic. The higher proliferation rate with DFX 3µM was due to the combination of decreased apoptotic cells at day 10 (D10) (p=0.03) and D14 (p=0.007) and increased cycling cells at D10 (p=0.0001). Regarding clonogenic assays, there were more CFU-E colonies with DFX 3µM (p=0,04). Despite the low concentration of DFX, cells exposed to DFX 3µM had a lower intracellular iron concentration measured by ICP-MS than control cells (p=0.019). Nevertheless, this decreased iron amount was not sufficient to activate cellular iron regulation by Iron Regulatory Proteins suggesting the absence of a direct effect of low dose DFX on iron homeostasis. Moreover, low dose DFX decreased intracellular and mitochondrial reactive oxygen species (ROS) at D14 (p=0.048 and p=0.03) and decreased the level of malonaldehyde (p=0,048), a product of lipid peroxidation. Then, we have investigated which signaling pathways were sensitive to DFX 3µM. We found an increased nuclear translocation of NFκB with DFX 3µM (p=0,028) in confocal microscopy (CM). Using RT-qPCR microarrays, we have analyzed target genes of NFκB. We found 4 upregulated genes (BIRC3, CASP8, CSF3, IRAK2) and 10 downregulated genes (FASLG, IL1R1, TLR9, PSIP1, CCL2, TRAF2, LTBR, TICAM2, CD27, TLR4) suggesting an anti-apoptotic and anti-inflammatory pattern. To demonstrate a link between the likely ROS modulation effects of DFX and the NFκB activation pathway, we have engineered a cellular model of inhibition of thioredoxin (TRX) by siRNA. TRX1 and 2 contribute to the cellular antioxidant response. Inhibition of TRX1 and 2 in iron overloaded medium led to increased ROS levels (p<0.0001; p=0.006, respectively) *versus* mock-transfected cells. In this model of iron overload and in the siTRX1 condition, DFX 3µM triggered activation of NFκB detected by both CM (p=0.04) and luciferase reporter assay (p=0.03). NFκB activation was absent in the knock-down (KD) of mitochondrial TRX (siTRX2) condition. Moreover, in non-iron overloaded medium condition, the level of ROS was not increased, and DFX in the TRX1 KD condition was not associated with NFκB activation. These results suggest that NFKB activation in this model is linked to TRX1 and regulated by an extremely fine control of ROS levels with a likely threshold effect.
Summary/Conclusions: Our study describes the pro-proliferative effects of low dose of DFX on erythroid progenitors in low risk MDS patients. These results provide a biological rationale for a clinical trial which will propose low dose of DFX in MDS patients, refractory to erythropoiesis stimulating agents.

Myelodysplastic syndromes – Clinical

EVALUATING ERYTHROBLAST PAS POSITIVITY IN THE DIAGNOSTIC APPROACH OF MYELODYSPLASTIC SYNDROME

R. Invernizzi[1,*], E. Travaglino[1], R. Bastia[1], I. Ambaglio[1], F. Quaglia[1], E. Boveri[1], M. G. Della Porta[1], L. Malcovati[1], M. Cazzola[1]
[1]IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: According to WHO minimal morphological criteria for myelodysplastic syndrome (MDS) diagnosis, at least 10% of bone marrow (BM) cells of at least one hematopoietic lineage must show unequivocal dysplasia to be considered as dysplastic. Morphological abnormalities of erythroid cells include cytoplasmic Periodic acid-Schiff (PAS) positivity, but the diagnostic power of this cytochemical reaction is not yet fully clear.
Aims: The aims of our study were to evaluate the diagnostic significance of erythroblast PAS positivity in MDS and to investigate a possible correlation between levels of PAS positivity and other morphological and clinical features.
Methods: We retrospectively examined the results of the cytochemical PAS staining for glycogen in BM smears from 165 patients with MDS, 116 patients with non-clonal cytopenia and 49 healthy subjects. We developed a PAS score by counting 100 nucleated cells for the erythroid lineage and classifying them according to their degree of PAS reactivity. The discriminant power of both PAS positivity rate and score for MDS identification was evaluated in comparison with that of the conventional morphological features of dyserythropoiesis; then, PAS positivity was included into the morphological scoring system we have previously defined (Leukemia 2015;29:66-75).
Results: PAS positive erythroblasts were observed in 104 (63%) MDS patients, 46 (40%) patients with non-clonal cytopenia, and 12 (24%) non-cytopenic controls, with a significant difference between MDS and non cytopenic controls ($p<0.0001$) or non-clonal cytopenias ($p=0.0001$), but not between healthy controls and non-clonal cytopenias ($p=0.09$). In MDS, both positivity rates (median 2%, range 0-33) and scores (median 2, range 0-53) were significantly higher than those in normal and pathological controls ($p=0.0001$ and $p=0.0004$ for rate, $p=0.0001$ and $p=0.0002$ for score, respectively), without significant difference in relation to excess blasts or multilineage dysplasia. MDS patients with >4% ring sideroblasts (RS) showed lower PAS positivity rates and scores than MDS patients with<4% RS ($p=0.0332$ and $p=0.0412$, respectively). In MDS-RS, erythroblast PAS positivity was not influenced by *SF3B1* mutation status. In MDS, no significant relationship was detected between erythroblast PAS positivity and percentage of BM blasts, percentage of BM erythroblasts, dyserythropoiesis grading, or Hb levels, whereas an inverse correlation was noticed between PAS score values and internuclear bridging ($r=-0.23$, $p=0.0395$). A ROC curve analysis allowed us to identify a PAS score value ≥1 (AUC=0.697, $p=0.0008$) and a PAS positive erythroblast percentage ≥1% (AUC=0.674, $p=0.0034$) as optimal cutoff to discriminate MDS patients from non-clonal cytopenias. Considering the most discriminant morphological features for dyserythropoiesis, the weight of both PAS positivity rate and score in the identification of BM dysplasia was lower than that of ring sideroblasts and megaloblastosis, but higher than that of defective hemoglobinisation, nuclear lobulation, multinuclearity, cytoplasmic fraying, pyknosis, and internuclear bridging. Integrating conventional parameters and PAS results significantly improved the sensitivity of our morphological scoring system.
Summary/Conclusions: The evaluation of BM erythroblast PAS positivity, easy to perform and inexpensive, may be useful in the work-up of patients with suspected MDS, especially if there is only unilinear dysplasia without ring sideroblasts or excess blasts.

E1180

A PHASE 3 RANDOMIZED PLACEBO (PBO)-CONTROLLED DOUBLE-BLIND TRIAL OF DARBEPOETIN ALFA IN LOW OR INTERMEDIATE-1 (INT-1) RISK MYELODYSPLASTIC SYNDROMES (MDS)

U. Platzbecker[1,*], A. Symeonidis[2], E. Oliva[3], J. Goede[4], M. Delforge[5], J. Mayer[6], B. Slama[7], S. Badre[8], E. Gasal[8], B. Mehta[8], J. Franklin[8]
[1]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik I, Dresden, Germany, [2]Division of Hematology, Department of Internal Medicine, University of Patras Medical School, Patras, Greece, [3]Division of Hematology, Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy, [4]Division of Hematology, University Hospital and University of Zürich, Zürich, Switzerland, [5]University Hospital Leuven, Leuven, Belgium, [6]Department of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic, [7]Centre Hospitalier Departemental, Avignon, France, [8]Amgen Inc., Thousand Oaks, United States

Background: There is a lack of PBO-controlled data for erythropoiesis-stimulating agents (ESAs) in MDS.
Aims: To evaluate darbepoetin alfa (DAR) in IPSS low/int-1 risk MDS (EudraCT2009-016522-14, NCT01362140).
Methods: Patients with MDS per WHO 2008 criteria with IPSS low/int-1 risk, anemia [hemoglobin (Hb)≤10 g/dL], low transfusion burden, no previous treatment with ESAs or biologic response modifiers, and serum EPO≤500mU/mL were randomized 2:1 to 24 weeks (wk) SC DAR 500 µg or PBO every 3 wk (Q3W), stratified by IPSS, then 48 wk open label (OL) DAR; follow-up is ongoing. Doses were withheld for Hb>12g/dL and decreased if Hb increased by >1.5 g/dL in 3 wk. Key endpoints were transfusion incidence and HI-E per IWG 2006.
Results: Randomized patients [N=147] had median Hb of 9.3 (min-max:5.5-10.6) g/dL and median baseline EPO of 69 (min-max:4.3-497) mU/mL; WHO classification was RA:15%, RARS:14%, RCMD:44%, del5q:9%, RAEB-1:16%, and MDS-U/unknown:2%. Transfusion incidence wk 5-24 was significantly reduced with DAR [DAR:36.1% *vs* PBO:59.2%, $p=0.008$]. In the 48-wk OL DAR period, 50.8% of patients had transfusions. More DAR patients achieved HI-E in the double blind period [DAR:14.7% (11/75 evaluable) *vs* PBO:0% (0/35 evaluable), $p=0.016$]. In the 48-wk OL DAR period, 34.7% (34/98) of patients achieved HI-E. Improved HI-E and transfusion responses were seen with more favorable status for IPSS-R but not IPSS. In the 48-wk OL DAR period, dose frequency increased from Q3W to Q2W in 81% of patients; doses were held/reduced frequently. Safety results from this trial were consistent with the previous DAR phase 2 MDS trial, with similar AML rates in PBO and DAR arms.

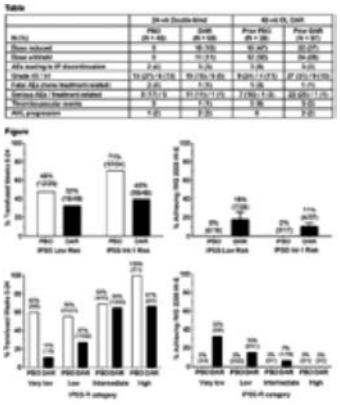

Figure 1.

Summary/Conclusions: In this phase 3, randomized, double-blind, PBO-controlled trial in anemic IPSS low/int-1 risk MDS patients, 24 wk of darbepoetin alfa Q3W significantly reduced transfusions and increased HI-E rates with no new safety signals. Most patients met criteria to change to Q2W dosing during the 48-wk OL period, suggesting that Q2W dosing may offer more benefit. The true clinical benefit of darbepoetin alfa may have been underestimated due to the nature of IWG 2006 HI-E criteria and trial design (Hb measured Q3W, dosing rules).

E1181

PRELIMINARY ANALYSIS OF EFFICACY AND SAFETY OF SINTRA-REV CLINICAL TRIAL, LENALIDOMIDE *VS* PLACEBO PHASE 3 STUDY IN LOW/INT-1 MDS PATIENTS WITH DEL(5Q) AND TRANSFUSION INDEPENDENCY

Background: Lenalidomide (LEN) is the first choice of treatment in low risk MDS patients with isolated de(5q) (MDS-del(5q)) and transfusion dependency (TD). Most of the low risk MDS-del(5q) patients diagnosed with anemia and independent of transfusions developed TD or needed treatment for symptomatic anemia early after diagnosis (median of 20 months, *abstract 3180 ASH, 2016*). LEN directly targets the del(5q) clone improving anemia, quality of life and survival in these subset of patients. For these reasons, the use of LEN in patients with del(5q), anemia and not TD seems to be very attractive. However, data about the use of LEN in MDS 5q- patients and transfusion independency (TI) are scanty, some retrospective studies suggest a benefit with the early use of LEN in this setting, but there is not already available any prospective and randomized study to confirm this likely advantage.
Aims: Our aims were to analyze efficacy and safety at week 12 of treatment with LEN *vs* Placebo in this setting of low risk MDS del(5q) patients with anemia and not in TD at diagnosis
Methods: From 2010 to 2017, 47 patients have been included in the Sintra-Rev trial, a phase III, multicenter, randomized and double blind study with LEN (5mg/day) *vs* placebo [2:1 randomization] in Low – Int-1 risk (IPSS) MDS del(5q) patients with anemia but TI. Preliminary results of efficacy (according to the IWG 2006 criteria for erythroid [HI-ER] and cytogenetic response [CyR]) and safety has been analyzed at week 12. Progression disease (DP) in the trial was defined as the development of TD.

Table 1.

Table 1. Main clinical characteristics (N=47)	
Age median (range)	72 (37-89)
Gender M/F	7/40
Hb (g/dL) median (range)	9.7 (7.1-11.7)
Platelets median (range)	263 x 10^9/L (104–761)
Neutrophils median(range)	2.18 x 10^9/L (0.69–16)
%Blasts in BM median (range)	2 (0-9)
IPSS-R (n [%])	
• Very-low	15 (31.9%)
• Low	26 (55.3%)
• Int	2 (4.3%)
• No info	4 (8.6%)
Cytogenetics:	
• Del5q alone	39 (83%)
• Del5q + other Cy abn	2 (4.3%)
• Unknown	6 (12.8%)

Results: Main clinical characteristics are summarized in **table 1**, 85% were females, median age was 72 years (37-89) and most of patients (95%) had del(5q) as the only cytogenetic abnormality. Among 47 patients, only 38 were evaluable at week 12 (5 out of 38 discontinued the study: 3 due to DP, 1 due to toxicity and 1 for unknown reasons), 7 patients are currently receiving the first 12 weeks of treatment and 2 patients were excluded (screening failures). Regarding efficacy (w12), data from 36 patients were available. HI-ER was observed in 14/36 patients (39%), minor HI-ER (Hb increased<1.5g/dL) in 4/36 (11%), stable disease in 15/36 (42%) and PD (transfusion dependency) in 3 (8%). CyR was available in 30 patients: complete CyR was obtained in 12 (40%), partial CyR in 6 (20%) and no CyR in 12 (40%) patients. Safety information in 38 patients demonstrated that most patients (87%) developed any adverse events (AE) while only 42% of these were relevant (G3-4). Most G3-4 AE were hematological (neutropenia 38%) being non-hematological only in 5%. Seven serious AE were reported in 5 patients: vestibular neuritis, congestive heart failure, polyarthritis, arterial hypertensive crisis, carpal arthritis, respiratory infection and chronic obstructive pulmonary disease exacerbation. All SAE were not related with the drug of the study (LEN/Placebo).
Summary/Conclusions: In this study we confirm a high rate of erythroid and cytogenetic responses early after treatment with an adequate safety profile in the first 12 weeks of treatment with LEN or placebo.

E1182

MYELODYSPLASIA-RELATED MORTALITY REMAINS THE MAIN CAUSE OF DEATH ALONG DIFFERENT GROUPS OF RISKS: AN ANALYSIS FROM MDS ARGENTINEAN STUDY GROUP

A.L. Basquiera[1], A. Enrico[2,*], J. Arbelbide[1], E. Nucifora[1], M. Iastrebner[3], G. Flores[4], J. Gonzalez[4], R. Crisp[5], V. Novoa[6], G. Alfonso[7], M. de Dios Soler[8], Y. Bestach[9], I. B. Larripa[9], C. Belli[10]

[1]Hematology, Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires (CABA), [2]Hospital Italiano de La Plata, La Plata, [3]Sagrado Corazon, [4]Hematology, Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), [5]Hospital Nacional Prof A Posadas, Buenos Aires, [6]Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), [7]Hematology, Hospital Nacional Prof A Posadas, Buenos Aires, [8]Hospital Curie, [9]Instituto de Medicina Experimental (IMEX-CONICET), Ciudad Autónoma de Buenos Aires (CABA), Argentina, [10]Laboratorio de Genetica Hematologica, Instituto de Medicina Experimental (IMEX-CONICET), Ciudad Autónoma de Buenos Aires (CABA), Argentina

Background: Myelodysplastic syndrome (MDS) are the most frequent hematological malignancy in elderly patients. The impact of MDS burden over overall mortality remains controversial, moreover, after the incorporation of hypometilating agents in the therapeutic armamentarium.
Aims: We aimed to analyze overall mortality and causes of death in our population of patients with MDS.
Methods: A retrospective analysis of patients with MDS reported to Argentinean MDS registry and a previous study from Academia Nacional de Medicina. Causes of death were classified in: acute myeloid leukemia (AML), infections, bleeding, solid tumor, cardiovascular, transplant related mortality (MRT), others and unknown. AML, infections and bleeding were considered as MDS-related mortality. Causes of death were analyzed using cumulative competitive events curves with Gray test and Fine-Gray for proportional hazard regression was used for the multivariate analysis.
Results: From 1981 to 2016, 1040 patients with MDS were recorded; 717 out of 1040 (69%) were diagnosed after 2006. Median age of patients was 70 years (range: 14-95 years) with 588 (56%) being male. MDS was primary in 974 patients (94%). Median follow-up of 25 months (range: 1-170 months) for the surviving patients. The cumulative incidence of overall mortality was 20% at 12 months (95%CI 2-22), 37% at 24 months (95%CI 3-40) and 59% at 60 months (95%CI 5-63). The incidence of overall mortality did not significantly differ along the years of diagnosis (p=0.291) neither according to age group. Multivariate analysis for cumulative incidence of overall mortality found Charlson index (HR 1.38; p<0.001), sex (HR 1.45; p=0.014) and IPSS-R (HR 2.79; p=<0.001) as prognostic variables. The main cause of death was AML accounting for 9% at 12 months (95%CI 7-11), 16% at 24 months (14-19) and 25% at 60 months (95%CI 22-28) of mortality for all patients. Infection-mortality and bleeding-mortality were the second and the third cause of death respectively. MDS-related mortality was 16% at 12 months (95%CI 13-18), 29% at 24 months (95%CI 26-32) and 44% at 60 months (95%CI 40-48); this incidence was not different by year of diagnosis. MDS-related mortality remained the main cause of death in all IPSS-R groups and in all Charlson index categories. Multivariate analysis for cumulative incidence of MDS-mortality found Charlson index (HR 1.29; p=0.02), IPSS-R (HR 2.88; p<0.001) and sex (HR 1.47;p=0.03) as independent variable. Age (p=0.034) and IPSS-R (p<0.001) were associated with AML-related mortality. A total of 56 patients underwent allogeneic transplant; cumulative incidence of MRT for all cohort was 0.5% at 12 months (95%CI 0.2-1.2) and 1.4% at 24 months (95%CI 0.8-2.4). Only male sex was associated with a higher cumulative incidence of mortality by solid tumor (p<0.001) and a Charlson index ≥2 was associated with higher cumulative incidence of cardiovascular mortality (p=0.021).
Summary/Conclusions: In this large cohort of patient with MDS we demonstrate that MDS-related causes are the leading cause of death along all IPSS-R groups. The absence of difference in mortality along the years of diagnosis highlights the necessity of better treatments for these patients.

E1183

PROSPECTIVE STUDY OF FLOW CYTOMETRY OF BONE MARROW IN 105 CONSECUTIVE PATIENTS WITH CYTOPENIA AND SUSPICION OF MYELODYSPLASTIC SYNDROME: STRONG CORRELATION WITH RISK OF AML-EVOLUTION AND SURVIVAL

F. Marco De Lucas[1,*], Z. Díez Gallarreta[1], B. Blázquez[1], P. Isusi[1], B. Dávila[1], C. Barrenetxea[1], A. Blanco[1], B. Barreña[2], S. Herráez[1], I. Capel[3], I. Leal[1], J. Uriarte[1], C. Alonso Caballero[1], J.I. Rodríguez[1], J.A. Márquez[1]
[1]Hematología, 2genetica, Hospital Universitario Basurto, 3facultad De Medicina Upv, Bilbao, Spain

Background: Diagnosis of myelodysplastic syndromes (MDS) remains a challenge, specially in patients with scant displastic morphology features and/or in the absence of cytogenetic changes. Multiparametric flow cytometry (MFC) findings have been recognized as a co-criterion for the diagnosis of MDS and have also demonstrated prognostic value in some studies. Nevertheless, this diagnostic tool is not fully implemented for the study of MDS in many centers and data from real life out of investigational studies are few.
Aims: To prospectively assess the value of MFC in the diagnosis of MDS in our center and correlate its findings to the clinical outcome of patients in terms of overall survival, transfusional needings, risk of hospitalization and evolution to acute leukemia.
Methods: We studied bone marrow samples from 105 consecutive patients submitted to our hospital between January 2013 and Abril 2015 because of one or more cytopenia and suspicion of MDS. Cytomorphology of every sample

was evaluated by at least two morphology experts and a consensus diagnostic of MDS-confirmed, MDS-suspected or MDS-excluded was emitted. MFC was performed applying at least five-colour staining and a numerical score was calculated for every patient following criteria defined by Ogata *et al* (Blood. 2006 Aug 1; 108(3):1037-44), with a score >=2 suggesting MDS. Conventional karyotype and FISH employing probes to detect usual 5q-, 7q-, +8, 20q- and delTP53 were performed in all cases.

Results: Median age of the patients was 73.5 y/o. Patients presented with anemia in 88 cases (84%), neutropenia in 36 (34%) and thrombopenia in 49 (47%). Cytomorphology was reported as MDS-confirmed (60 pts), MDS-excluded (22) or MDS-suspected (23). MDS subtypes were Multilineage Dysplasia (23), Unilineage Dysplasia with Ring Sideroblasts (4), Blast Excess (14), Multilineage Dysplasia with Ring Sideroblasts (9), del5q Syndrome (3) and Unclassified (2), 4 pts being diagnosed of CMML. MFC score was MDS-suggestive in 56 cases, MDS-not suggestive (36) and in 13 cases its use was precluded because of morphology findings. Considering cytomorphology as gold standard, and excluding those patients with MDS-suspected but not confirmed, MFC score sensitivity was 77%, especificity 88%, with positive and negative predictive values of 96% and 56% respectively. Furthermore, MFC-score showed a significant correlation with single morphologic findings of granulocytic (p<0.001), erythroid (p=0.001) and megakaryocytic displasia (p=0.002), and a trend to significant association with del7q by FISH (p=0.085). In the subset of patients with MDS-suspected but not confirmed by morphology, the presence of a MFC score >=2 was significantly associated with a poorer overall survival (log-rank p=0.012), with all MFC score <2 patients alive after a median follow-up of 35 months. There was also a trend to statistical association between MFC findings and overall survival in the whole series of patients (log rank p=0.053). Interestingly, there was a striking difference in risk of evolution to AML according to MFC findings (log rank=0.013), with a 100% of patients free from this complication in the group of patients with MFC score <2.

Summary/Conclusions: MFC analysis of the bone marrow provides useful information in the diagnosis of MDS which can be specially helpful in the subset of patients with inconclusive morphological findings, showing a strong correlation in this group of patients with clinical outcome in terms of risk of evolution to AML and overall survival.

E1184

ECONOMIC IMPACT AND HEALTHCARE UTILIZATION IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell[1,*], A. Galaznik[1], E. Farrelly[2], M. Blazer[2], H.-C. Shih[2], A. Raju[2], A. Ogbonnaya[2], M. Eaddy[2], R. Fram[1], D. Faller[1]

[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [2]Xcenda, Palm Harbor, United States

Background: Therapy for patients with HR-MDS includes systemic chemotherapy, stem cell transplant (SCT), and supportive care aimed at improving symptoms associated with MDS-related disruption of normal hematopoiesis. However, the economic impact of these interventions over time for HR-MDS patients has not been fully examined.

Aims: We evaluated the costs and healthcare utilization (HCU) of US HR-MDS patients treated during routine care.

Methods: Newly diagnosed adult HR-MDS patients who initiated first-line therapy were identified from Optum, a large US claims database, between 1/1/08 and 10/31/15. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with ≥1 HR-MDS ICD-9/10 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: lack of continuous enrollment in medical/pharmacy benefits in the 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during baseline period. MDS-related and non-MDS-related HCU and costs incurred during follow-up were evaluated. MDS-related HCU and costs were medical claims with a primary diagnosis of MDS or MDS-related treatment (ie, MDS chemotherapy as defined by NCCN MDS Guidelines v2.2017 or MDS-directed supportive care which included hydroxyurea, erythrocyte- and colony-stimulating- growth factors and erythrocyte/platelet transfusions) and pharmacy claims for MDS treatment. Proportions of patients with HCU were reported. Costs were calculated as per-patient-per-month (PPPM) costs adjusted to 2015 US dollars and reported as mean (standard deviation [SD]). Patients with a capitated payment plan were excluded from the cost analysis. Patients were followed until death, progression to acute myeloid leukemia (AML), end of continuous enrollment, or end of study (12/31/2015).

Results: 209 treated HR-MDS patients were identified. During the follow-up period, 69.4% of patients had ≥1 inpatient admission, but more patients had an MDS-related than non-MDS-related admission (Table 1). 56.9% of patients had ≥1 emergency room visit over the follow-up period; visits were predominately for non-MDS-related services. The majority of patients had ≥1 physician office visit (91.9%) and other outpatient visits (99.5%). Over the follow-up period, the mean PPPM cost was $17,361 (SD: $19,747) (Table 1) and was higher in Year 1 than in Year 2 ($17,337 [SD: $19,696] *vs* $12,976 [SD: $14,135]). The majority of costs overall were for MDS-related medical services ($10,327 PPPM, SD: $11,050). Between Years 1 and 2, MDS-related medical PPPM costs decreased from $10,557 (SD: $11,164) to $6,530 (SD: $7,406) while non-MDS-related medical PPPM costs remained fairly constant in both years. Chemotherapy and supportive care medical services were the main drivers of MDS-related medical costs, also decreasing from Year 1 to Year 2. Non-MDS-related costs accounted for a smaller portion of the overall medical PPPM costs ($6,124 [SD: $15,158]); and remained relatively similar in Years 1 and 2.

Table 1.

Table 1. HCU & Cost (Overall, Year 1 & 2 Post-index) for Treated HR-MDS Patients

Proportion with HCU, %[a]	Overall (N=209)	Year 1 (N=209)	Year 2 (N=92)
Inpatient Visit (≥1)	69.4	57.9	37.0
MDS-related vs non-MDS-related	57.9 vs 41.6	48.3 vs 33.5	23.9 vs 18.5
ER Visit (≥1)	56.9	51.2	34.8
MDS-related vs non-MDS-related	12.0 vs 55.0	9.1 vs 48.8	5.4 vs 32.6
Physician Office Visit (≥1)	91.9	90.4	81.5
MDS-related vs non-MDS-related	82.3 vs 89.0	81.3 vs 87.6	72.8 vs 75.0
Other Outpatient Visits (≥1)	99.5	98.6	91.3
MDS-related vs non-MDS-related	96.2 vs 99.0	93.3 vs 97.6	73.9 vs 90.2
Cost, mean $ in PPPM (SD)	**Overall (N=149)**	**Year 1 (N=149)**	**Year 2 (N=62)**
Total	17,361 (19,747)	17,337 (19,696)	12,976 (14,135)
MDS-related	10,839 (11,101)	11,068 (11,217)	6,995 (7,433)
Non- MDS-related	6,522 (15,181)	6,268 (15,093)	5,980 (11,637)
Medical	16,451 (19,203)	16,427 (19,111)	11,971 (14,104)
MDS-related	10,327 (11,050)	10,557 (11,164)	6,530 (7,406)
Non- MDS-related	6,124 (15,158)	5,870 (15,093)	5,980 (11,637)
Pharmacy	910 (2,342)	909 (2,419)	1,005 (2,320)
Selected Medical Costs Components			
Inpatient	**4,904 (14,703)**	**4,655 (14,644)**	**4,079 (11,184)**
MDS-related	1,175 (4,670)	1,205 (4,829)	873 (3,917)
Non- MDS-related	3,729 (14,003)	3,451 (13,930)	3,206 (10,272)
Physician Office	**997 (1,749)**	**1,031 (1,908)**	**736 (1,162)**
MDS-related	639 (1,483)	681 (1669)	424 (695)
Non- MDS-related	358 (490)	351 (513)	312 (679)
Other Outpatient	**3,419 (3,938)**	**3,491 (4,179)**	**3,328 (5,844)**
MDS-related	1,602 (2,281)	1,644 (2,456)	1,613 (4,635)
Non- MDS-related	1,817 (2,826)	1,847 (2,995)	1,716 (3,241)
Chemotherapy	**3,161 (2,106)**	**3,304 (2,157)**	**1,888 (2,134)**
Supportive Care	**3,700 (9,134)**	**3,678 (9,174)**	**1,652 (2,897)**

[a] MDS-related vs non-MDS-related are not mutually exclusive groups; patients could be in both categories, and percentages are relative to the overall "n" in the column as the denominator.
Key: ER – emergency room; HCU – healthcare resource utilization; HR-MDS – higher-risk myelodysplastic syndrome;; PPPM – per patient per month; SD – standard deviation

Summary/Conclusions: The economic impact of HR-MDS is considerable, with higher costs incurred within the first year of diagnosis. The decrease in cost between Year 1 and Year 2 was mainly due to decreased MDS-related medical costs. Consistent with this cost trend, healthcare utilization for MDS-related services decreased in Year 1 *vs* Year 2. As treatment of HR-MDS continues to evolve, economic impact and HCU need to be further investigated in this patient population.

E1185

INTRAVENOUS IMMUNOGLOBULIN IS AN EFFECTIVE TREATMENT FOR CYTOPENIAS ASSOCIATED TO CIRCULATING T-CELL CLONES IN MYELODYSPLASTIC SYNDROMES

F. Schieppati[1,*], E.P. Demakos[2], R. Odchimar-Reissig[2], S.C. Navada[2], L.R. Silverman[2]

[1]Hematology, ASST Spedali Civili di Brescia, Brescia, Italy, [2]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States

Background: Myelodysplastic syndrome (MDS) can be associated with immunologic disorders, including autoimmune cytopenias and Coombs positive or negative (C±) hemolytic anemia. Abnormally expanded T-cells can be detected in these patients, possibly contributing to both bone marrow insufficiency and peripheral cytopenia, and offer another target for therapeutic intervention.

Aims: To explore the role of intravenous immunoglobulin (IVIG) as a treatment for immune-related cytopenia in a series of 20 consecutive patients with MDS at a single institution.

Methods: T-cell clonal expansion in the peripheral blood (PB) was documented by flow cytometry and PCR. Eighteen patients had a confirmed MDS (16 IPSS lower-risk, LR). Two suspected MDS were designated as idiopathic cytopenia of uncertain significance (ICUS). Reasons for IVIG treatment were chronic hemolysis refractory to corticosteroids (16: 12 LR, 1 higher-risk (HR), 1 ICUS) or pancytopenia (2 LR and 1 HR refractory to standard therapy, 1 ICUS) associated to a T-cell clonal proliferation in the PB. Hematological response was assessed by IWG criteria 2006. Hemolysis response (HLR) included normalization (CR) or a greater than 50% improvement (PR) of LDH, reticulocytes, indirect bilirubin and haptoglobin.

Results: Clinical characteristics are shown in the Table. All patients had a clonal rearrangement of TCR by PCR (10 TCRβ, 8 TCRβ+TCRγ, 2 TCRγ). In 9 cases the clone was characterized by flow cytometry: 6 had a CD3+ T-cell and 3 had a CD3-/CD16+/CD56+ NK-cell expansion. Associated immunologic disorders were: ITP (4), neutrophil dermatosis (3), inflammatory bowel disease

(3), seronegative arthritis (2), connectivitis (2). One patient with hypoplastic MDS had LGL liver involvement. Coombs test was positive in 4/16 hemolysis cases. From Jan-'10 to Jan-'17, IVIG was administered at a dose of 500mg/kg once per week, in cycles of 1 to 4 weeks. The ORR was 75% (15/20): all patients showed an erythroid hematological improvement (HI) (100%). Platelets and neutrophil HI was seen in 50% and 80% of responsive cases, respectively. HLR occurred in 13/16 (81%: 4 CR and 9 PR). Median number of cycles and duration of treatment were 11 and 12 months (mo), respectively. The HLR-CR was stable in 7 patients; 4 relapsed from HLR but subsequently responded by shortening the intervals between administrations of IVIG; 2 were secondary refractory. Eventually, 6 responders became refractory to IVIG. Response was more durable with continuous rather than sporadic dosing. Median time to response was 1 mo. Median duration of response was 39 mo. Corticosteroids were discontinued in 5/10 patients and reduced in 5/10. Adverse events were: 1 palpitations (G1); 1 hypertension (G1). Responders had lower platelet counts ($p<0.05$), but no other clinical differences compared to non-responders. However, the 5-year OS rate was higher in the responders to IVIG: 53% compared to 30% ($p=0.08$).

Table 1.

	All (20)	Responders (15)	Non-responders (5)	P value
Age, median	71.5	73	70	ns
Male, n.	16	11	5	ns
Hemoglobin, median	7.45	7.5	7	ns
Platelets, median	58	55	308	<0.05
ANC, median	1.7	1.09	2.87	ns
Reticulocytes, median	4	4.2	3.5	ns
LDH, median	266	272	259	ns
Bilirubin indirect, median	1.2	1.4	0.9	ns
Haptoglobin, median	48	17	79	ns
Coombs test IgG ± C3D, n.	4	4 (weak)	0	ns
IPSS low-int1 (=lower-risk), n.	16	11	5	ns
IPSS int2-high (=higher-risk), n.	2	2	0	ns
Cytogenetics unfavorable, n.	5	4	1	ns
Splenomegaly, n.	8	7	1	ns
Immunologic disorders, n.	9	6	3	ns

Summary/Conclusions: Treatment with IVIG of C± hemolytic anemia and pancytopenia associated with T-cell immune-clones and MDS was safe and yielded high rates of durable response on all lineages and on hemolysis. Transfusion independency and reduction/discontinuation of corticosteroids for chronic hemolysis make this drug a valuable option not only in LR but also in HR patients, although a confirmation on larger cohorts is needed. IVIG at intermediate-high dose suppresses proliferation of T-cells and induces immune-regulation. Given the relative rarity of T-cell clones in MDS, further investigational studies are underway to define their pathogenetic role and the mechanism of action of IVIG in this specific subset of patients.

Background: The clinical presentation of myelodysplastic syndromes (MDS) is highly variable, and the ability to accurately predict outcomes is critical. Current prognostic systems for these diseases are based on traditional clinical, pathologic and laboratory indicators.
Aims: We aimed to develop and validate a new prognostic index for advanced MDS by including self-reported fatigue severity into a well-established clinical risk classification: the International Prognostic Scoring System (IPSS).
Methods: Untreated patients (n=280) were recruited at the time of diagnosis of advanced MDS from 37 hospitals in nine countries to create the index. The index was then applied to an independent cohort including pre-treated MDS patients from the Dana-Farber Cancer Institute (DFCI) in Boston, Massachusetts (USA; n=189). Patients in both the International and DFCI cohorts were adults with newly-diagnosed intermediate-2 or high-risk MDS (advanced disease on the IPSS). Patients were enrolled regardless of age, comorbidity, performance status and progression from a lower IPSS category. All completed a baseline health-related quality of life assessment. Data from international and DFCI cohorts were independently collected and analyzed. Univariate and multivariate Cox proportional hazards (PH) regression analyses were performed to estimate hazard ratios with 95% Confidence Intervals (CIs). Discrimination and calibration were evaluated for both the development (internal validation) and independent DFCI datasets (external validation). Statistical significance for all tests was set as two-sided $\alpha=0.05$.
Results: A new risk classification was developed, namely, the fatigue (FA)-IPSS(h). Whereas use of the standard IPSS in more advanced disease discriminates between two risk categories for untreated patients, the new fatigue FA-IPSS(h) classification was able to distinguish three subgroups of patients with distinct survival outcomes. Overall survival rates at 6 months, 1 year, and 2 years were markedly different among the three groups. To illustrate, one year survival was 80.3% (95% CI, 73.4;87.8), 60.5% (95% CI, 52.3;70.0) and 37.6% (95% CI, 23.9;59.1) for patients classified into Risk-1, Risk-2 and Risk-3 respectively. Median OS in DFCI data by FA-IPSS(h) risk was similar to that of the development cohort for each of the three risk groups, indicating good external calibration. Patterns of OS through 2 years were also distinct between risk groups as in the development cohort of untreated patients, with one exception: 2–year OS was similar for FA-IPSS(h) risk-3 and risk-2. Predictive accuracy of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.61 *vs* 0.57) as well as in the independent cohort including pre-treated patients (C-statistic, 0.58 *vs* 0.54).
Summary/Conclusions: The FA-IPSS(h) is an additional prognostic tool that might enhance clinicians' ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.

E1187

PROGNOSTIC AND THERAPEUTIC IMPLICATIONS OF SIGNIFICANT MARROW FIBROSIS IN COMBINATION WITH P53 OVER-EXPRESSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME: A SINGLE CENTRE STUDY

E. Groarke[1,*], S. Maung[1], K. Ewins[1], M. Jeffers[2], B. MacDonagh[1], J. McHugh[1], R. Desmond[1], H. Enright[1]
[1]Department of Haematology, [2]Department of Cellular Pathology, Tallaght Hospital, Dublin 24, Ireland

Background: Myelodysplastic syndromes (MDS) are defined in the WHO 2016 classification as a group of clonal bone marrow neoplasms characterized by ineffective hematopoiesis, morphologic dysplasia in hematopoietic cells and peripheral cytopenia(s)[1]. They present as a diverse phenotype with some patients requiring merely observation while others require more intensive management due to significant marrow failure and the risk of development of acute leukaemia. The presence of significant marrow fibrosis has previously been shown to be a poor prognostic factor in patients with MDS, with reduced overall survival[2]. Significant marrow fibrosis has also been associated with both the presence of the TP53 gene mutation and with p53 over expression, which is a known adverse prognostic risk factors in MDS patients[3].
Aims: To assess the presence of p53 expression in patients with moderate to severe marrow fibrosis (grade 2-3), observe its effect on overall survival in patients with marrow fibrosis, and determine whether the use of azacitadine had any impact on survival.
Methods: We conducted a retrospective study utilizing a hospital database of 247 patients with MDS diagnosed in a single center between 2000 and 2014. Of these patients, 200 had bone marrow trephine samples adequate for reticulin stain analysis, which was completed using the European consensus on grading bone marrow fibrosis (grades 0-3). P53 expression was examined using immunohistochemistry staining defined according to the modified quick scoring system. We then looked for an association between degree of marrow fibrosis and p53 expression. In patients with significant marrow fibrosis and p53 expression we examined overall survival and response to treatment with azacitadine.

Results: Overall, no significant correlation was seen between expression of p53 and degree of fibrosis (p=0.25). However, degree of fibrosis predicted for overall survival in patients with p53 expression (median overall survival of 4 months in patents with both p53 over expression and significant fibrosis compared with median overall survival of 18 months in patients with p53 over expression without fibrosis, p=0.001). In patients who received azacitadine, those with both significant fibrosis and p53 expression had a significantly increased overall survival compared with those who did not receive azacitadine (4 month *versus* 1 month, p=0.002). Azacitadine treatment was not associated with increased survival in patients with p53 expression without fibrosis but these patients did have an overall increased survival compared to those with fibrosis (median survival 12 *vs* 37 months).
Summary/Conclusions: This study confirms that significant marrow fibrosis adversely affects overall survival in patients with MDS, including those with p53 over expression. Patients who received azacitadine had a significant increase in median survival. Alhough the numbers of patients who received azacitadine were small, this data suggests that patients with fibrosis may benefit from the use of azacitadine and larger and randomized studies should be considered to study this further.

FACS PURIFICATION OF BLAST CELLS IN MDS IMPROVES THE FISH DETECTION RATE FOR DEL(5Q) AND DEL(20Q), BUT NOT FOR DEL(7Q) OR T8

M. Pereira[1,2,*], G. Marques[3], J. Lima[3], R. Reis[3], A. Coelho[3], L. Jorge[3], S. Pedreiro[4], L. Ribeiro[1], A. Paiva[4], F. Rodrigues[3]
[1]Clinical Hematology Department, Coimbra University Hospital Centre, [2]Faculty of Medicine, University of Coimbra, [3]Clinical Pathology Department, [4]Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Prognostication in Myelodysplastic Syndromes (MDS) using validated scores includes the detection of chromosomal aberrations by conventional karyotyping. When the latter is unavailable or unsuccessful, fluorescence in-situ hybridization (FISH) panels can be used. Although panels vary by laboratory, some of the most commonly used probes include the search for monosomy 5 or del(5q), monosomy 7 or del(7q), del(20q) and trisomy 8 (T8). In our Lab, FISH was historically performed on the whole unsorted patient sample (Full Sample); since 2015, we have primarily performed the analysis on Fluorescence Activated Cell Sorting (FACS) separated blast cells.
Aims: In this study, we aim to analyze the benefit of using purified samples of blast cells for FISH analysis in MDS, when compared to full mixed cellularity samples.
Methods: We reviewed all samples analyzed in our laboratory between January 1st 2011 and February 28th 2017 in which a FISH panel was performed due to a suspicion of myelodysplasia, using probes for del(5q), del(7q), del(20q) and T8. The proportion of patients positive for the test, as well as the proportion of positive cells within a positive sample, were compared.
Results: We obtained valid results for 328 samples during the relevant timeframe, 39.6% of which were collected from female patients. FISH was performed after FACS in one third of samples (35.1%, n=115), starting in 2015. Considering the overall cohort, nearly a quarter of samples (23.8%) had at least one aberration in the four probes tested in this study. This proportion of abnormal findings was nearly double in FACS patients (33.0%) compared to full sample patients (18.8%, p=0.004). **Del(5q)** was present in 5.6% of the cohort; however, positivity was 8-fold higher in FACS patients, compared to full sample patients (12.3% *vs* 1.6%, p<0.001). Considering the percentage of positive cells in each sample, it doubled from 38.7±29.9% in the full sample to 71.8±28.1% after FACS, p=0.08. **Del(7q)** was similarly present in 5.7% of the cohort; however, in contrast, there were no relevant differences between FACS patients, 4.2% of whom had del(7q), and full sample patients (8.1%, p=NS). There were, however, differences in the percentage of positive cells within the sample, doubling from 32.1±11.2% in the full sample to 77.6±17.8% after FACS, p<0.001. **Del(20q)** was identified in 7.0% of the overall tested cohort; the asymmetry in results was marked, with a 36-fold higher proportion of positive findings after FACS (18.7%) compared to full samples (0.5%, p<0.001). The percentage of positive cells doubled from 15% in the single positive test in the full sample cohort, to an average of 35.5±22.2% after FACS. Finally, **T8** was found in 10.2% of patients, a result which was uninfluenced by the type of sample used (10.2% in both full and FACS samples, p=NS). The percentage of positive cells once again doubled from 25.5±14.7% in the full sample to 53.3±28.1% after FACS (p=0.0008).
Summary/Conclusions: We found that one quarter of all patients who underwent a FISH panel workup for a suspected diagnosis of MDS presented with aberrations in at least one of the four selected probes, a proportion which was significantly lower (one fifth) when a full sample was analyzed, and significantly higher (one third) in FACS purified blast cells. Although the purification of the sample through FACS doubled the percentage of positive cells within each sample for all four probes, the likelihood of obtaining a positive result for del(7q) and T8 in the cohort was unaffected by the methodology used. In contrast, the use of a sorted sample greatly increased the proportion of positive findings in del(5q) and, especially, in del(20q), the two probes for which the basal positivity in full samples were lowest. The clinical value of this increased rate of detection of del(5q) and del(20q) remains unclear, since their prognostic utility has only been established for levels detectable by conventional karyotyping of a full sample.

E1189

COUNTING BONE MARROW BLASTS AS A PERCENTAGE OF NON-ERYTHROID CELLS PROVIDES SUPERIOR RISK STRATIFICATION FOR MDS PATIENTS WITH ERYTHROID PREDOMINANCE

A. Sun[1,2,*], Y. Yu[1], T. Zhang[1], Q. Wang[1], D. Liu[1], S. Chen[1], D. Wu[1,2]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Patients with erythroid predominance (≥50% erythroblasts, MDS-erythroid) compose a significant proportion of patients with MDS. The erythroid/myeloid subtype was divided from the AML category into MDS-erythroid by the 2016 WHO classification of myeloid neoplasms. At that time, there was no consensus on a more appropriate way of enumerating bone marrow (BM) blasts from TNCs or NECs in MDS-erythroid patients.
Aims: To clarify these questions, 1283 MDS patients were retrospectively analyzed in our center.
Methods: MDS-erythroid was observed in 27.0% of patients (346/1283), and these patients had similar clinico-pathological features and overall survival, with 937 cases of MDS with <50% ENCs.
Results: By calculating the percentage of BM blasts from NECs, 73 of 200 patients (36.5%) with MDS-erythroid who were diagnosed within WHO subtypes without excess blasts (EB) were moved into higher-risk categories and showed shorter OS than those who remained in the initial categories (P=0.041). Recalculating the International Prognostic Scoring System-Revised (IPSS-R) by enumerating blasts from NECs, 40 of 168 (23.8%) MDS-erythroid patients with relatively lower risk were re-classified as higher-risk and had significantly poorer survival than those who remained in the lower-risk category (P=0.030). This was especially true for the intermediate risk group that was stratified by IPSS-R (unchanged patients *vs* shifted patients, P=0.007). However, the impact of enumerating BM blasts from NECs on classification and prognostication was not evident in all MDS patients.
Summary/Conclusions: In conclusion, our results suggested that enumerating the percentage of BM blasts from NECs significantly improved the prognostic assessment of MDS-erythroid, especially for patients within the intermediate risk group stratified by IPSS-R.

E1190

SUCCESSFUL TREATMENT WITH DANAZOL FOR MYELODYSPLASTIC SYNDROMES AND APLASTIC ANEMIA REFRACTORY OR INELIGIBLE TO STANDARD THERAPY

F. Schieppati[1,*], A.M. Pelizzari[1], E. Borlenghi[1], M. D'Adda[1], E. Cerqui[1], D. Marocolo[1], G. Rossi[1]
[1]Hematology, ASST Spedali Civili di Brescia, Brescia, Italy

Background: The discovery of danazol potential activity on telomere elongation in bone marrow failure has renewed interest in this drug. The treatment of cytopenia in myelodysplastic syndromes (MDS) and aplastic anemia (AA) patients who fail or are ineligible to standard therapies is an unmet medical need; however only dated reports on danazol use in this setting are available.
Aims: We report the results of treatment with danazol in patients with MDS and AA at a single institution.
Methods: From Jun-'11 to May-'15, danazol was administered to 31 consecutive patients (20 MDS and 11 AA). Criteria for treatment were non-severe AA (8), severe AA ineligible/refractory to immunosuppressive therapy or allogeneic transplantation (3), transfusion dependent (TD) lower risk MDS refractory to erythropoietin (11), MDS with isolated thrombocytopenia <50x10^9/L (6) or with bone marrow hypoplasia and bicytopenia (3). Diagnosis was defined by WHO 2008 for MDS and according to Camitta (Blood 1975) for AA; response was assessed by IWG 2006 criteria.
Results: The characteristics of the patients are shown in the Table. All MDS patients had low-risk disease according to IPSS and IPSS-R, except 2 and 3 patients respectively. Nineteen patients (12 MDS, 7 AA) received danazol at full dose (600mg daily). A 400mg daily dose was given to 12 patients, due to toxicity (4 MDS, 4 AA) or comorbidities (4 MDS). Median duration of treatment

was 19 months (mo) (1-66) in AA and 6 mo (1-60) in MDS. ORR was 73% and 50%, respectively. Age and hemoglobin levels impacted on response in AA. Hematological improvement was seen on all lineages in 92% of cases, with a median time to best response of 3-5 mo on platelets and neutrophils and of 8-12 mo on hemoglobin. Interestingly, duration of response in MDS patients was significantly longer with a danazol dose of 600mg than with 400mg (p=0.001). Conversely, dosing did not impact on response to danazol in AA patients. Grade 2-3 toxicity was significantly higher in AA patients (p<0.05), 60% pretreated with IST. Adverse events included: hepatotoxicity (3 G1, 1 G2, 3 G3), muscle pain/CPK elevation (3 G1, 2 G2), transient renal impairment (1 G1), hyporexia (1 G1). Responders to danazol had a better survival in terms of OS and EFS in both groups (Figure 1).

Table 1.

	AA				MDS			
	TOT	R	NR	*p-value*	TOT	R	NR	*p-value*
Total	**11**	**8**	**3**	-	**20**	**10**	**10**	-
Male	6	4	2	ns	11	4	7	ns
Age	57	48	74	**<0.05**	70	69.5	73.5	ns
Hb g/dL	9.35	11.5	7.4	**<0.01**	8.9	8.6	8.9	ns
Plts x10⁹/L	21	24	6	ns	27	31	25	ns
ANC x10⁹/L	0.98	1.27	0.7	ns	1.7	1.7	1.7	ns
Cellularity%	20	20	30	ns	40	28	74	ns
TD%	5	2	3	ns	13	6	7	ns
Toxicity (G≥2)	5	-	-	-	2	-	-	**<0.05**

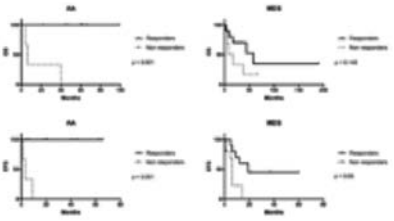

Figure 1.

Summary/Conclusions: Danazol was proved both effective and safe as treatment of cytopenia in MDS and AA patients refractory or ineligible to standard therapies. The daily dose of 600mg was more effective for MDS patients, whereas a lower dose of 400mg may have a better risk/benefit ratio in AA. Younger AA patients with less severe anemia were more likely to respond. Danazol use is particularly attractive in thrombocytopenic patients, where responses were rapid, but delayed responses may be expected also on anemia by using danazol for prolonged periods, when tolerated. Response to danazol is also potentially associated to a survival advantage, although these data should be confirmed by larger prospective studies.

E1191

SURVIVAL OUTCOMES IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell[1,*], A. Galaznik[1], E. Farrelly[2], M. Blazer[2], H.-C. Shih[2], A. Raju[2], A. Ogbonnaya[2], M. Eaddy[2], R. Fram[1], D. Faller[1]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [2]Xcenda, Palm Harbor, United States

Background: MDS is composed of multiple and rare hematological stem-cell disorders, resulting in cytopenias and disease-related complications and deaths. There are no robust trial data comparing the available treatment options for HR-MDS patients; and of the approved drugs, only azacitidine has demonstrated a statistically significant, but modest clinical impact on overall survival (OS).
Aims: We evaluated first-line treatment (1LT) choice and survival outcomes in a US cohort of HR-MDS patients engaged in routine care.
Methods: Newly diagnosed HR-MDS patients who were ≥18 years old and who had initiated 1LT were retrospectively identified from Optum, a large US claims database, between 1/1/2008 and 10/31/2015. HR status was based on ICD coding: ≥1 inpatient claim with an HR-MDS ICD-9/10 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22), or ≥2 outpatient claims with ≥1 HR-MDS ICD-9/10 code. The first MDS claim served as the index diagnosis date. Exclusion criteria included: absence of continuous care for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or stem-cell transplant (SCT) during the baseline period. 1LT was defined as MDS-specific treatment (MDS-Tx) (NCCN MDS Guidelines v2.2017)[1] and initiated after first HR-MDS claim (index date). Follow-up ended upon death, end of continuous enrollment, end of study, or progression to acute myeloid leukemia (AML) (except for OS). Transfusion independence (defined as ≥60 days with no evidence of erythrocyte [RBC] or platelet [PLT] transfusions) was evaluated in patients with ≥60 days of follow-up. Median progression-free survival (PFS) (defined as progression to AML, initiation of second-line therapy, or death) and OS, along with PFS and OS rates at 2 years following initiation of 1LT, were evaluated using unadjusted Kaplan-Meier analyses.
Results: 209 newly diagnosed HR-MDS patients initiating 1LT MDS-Tx were identified; mean age was 73 years (standard deviation [SD]: 10.1) and 61.2% were male. In the 12 months prior to diagnosis, 27.3% of patients used MDS-directed supportive care (ie, colony stimulating-, erythrocyte-, or thrombopoietic growth factors; RBC or PLT transfusions; or hydroxyurea). 1LT with hypomethylating agents (HMAs) predominated in 89.5% of patients (azacitidine, 68.9% and decitabine, 20.6%); 8.6% of patients received an immunomodulator monotherapy; and 8.6% of patients underwent SCT during follow-up. Of the 169 treated HR-MDS patients with ≥60 days of follow-up on 1LT, 51% achieved transfusion independence. For all treated HR-MDS patients, median PFS and 2-year PFS rates were 12.5 months (95% confidence interval [CI]: 9.1, 14.9) and 27.9%, respectively. OS rate at 2 years was 59.1%. Patients who achieved transfusion independence had a higher rate of 2-year OS (65.2% *vs* 53.8%) and PFS (36.3% *vs* 25.7%), but neither were statistically significant.

Table 1.

Table 1. PFS and OS Outcomes in Treated HR-MDS Patients in Routine Care

Outcome	Overall N=205[a]	Transfusion Independent N=87[b]	Transfusion Dependent N=82[b]
PFS from initiation of 1LT			
Median (95% CI), months	12.5 (9.1, 14.9)	16.5 (11.3, 23.8)	13.4 (8.9, 15.1)
		P=0.08	
1-Year Rate, %	51.5	61.7	57.0
		P=0.34	
2-Year Rate, %	27.9	36.3	25.7
		P=0.10	
OS from initiation of 1LT			
1-Year Rate, %	81.9	84.9	87.8
		P=0.73	
2-Year Rate, %	59.1	65.2	53.8
		P=0.61	

[a] Excludes the 4 patients treated with stem-cell transplant only.

[b] Includes only those treated in 1LT with ≥60 days of follow-up post-1LT initiation.

Key: 1LT – first-line therapy; CI – confidence interval; HR-MDS – higher-risk myelodysplastic syndromes; PFS – progression-free survival; OS – overall survival.

2. Fenaux P. et al. *Lancet Oncol*. 2009:10:223-232.

Summary/Conclusions: Survival outcomes in routine clinical care were higher than reported in clinical trials, specifically in HR-MDS trials with azacitidine.[2] Among patients able to achieve transfusion independence, a trend toward increased 2-year PFS and OS rates was observed, although statistical significance was not reached. Characteristics that contribute to variations in PFS and OS outcomes within the HR-MDS population need further investigation.

[1]UT MD Anderson Cancer Center, Houston, [2]Roswell Park Memorial Institute, Buffalo, [3]Cornell University Medical Center, New York, United States, [4]Hopital Maisonneuve-Rosemont, Montreal, [5]Sunnybrook Medical Center, Toronto, Canada, [6]University of Chicago, Chicago, [7]Dana Farber Cancer Institute, Boston, United States, [8]Princess Margaret Cancer Center, Toronto, Canada, [9]Hackensack University Medical Center, Hackensack, [10]Massachusetts General Hospital, Boston, [11]Medical College of Wisconsin, Milwaukee, [12]Astex Pharmaceuticals Inc., Pleasanton, [13]Vanderbilt University Medical Center, Nashville, United States

Background: We have previously shown that ASTX727, a combination of oral decitabine and the oral CDAi E7727, emulates the pharmacokinetics of a one hour intravenous decitabine infusion (IV-DAC) in a dose-escalation phase 1 study. (Garcia-Manero. Blood 2016 128:114)
Aims: To confirm pharmacokinetic (PK) and pharmacodynamic (PD) comparability of 20mg/m^2 IV-DAC administered D1-5 of a 28 day cycle with an entire cycle of ASTX727 given at the selected dose from phase 1 (35mg decitabine and 100mg of E7727).
Methods: Adult patients with Int-1/Int-2 or HR MDS or Chronic Myelomonocytic Leukemia (CMML) were enrolled in a randomized cross-over Phase 2 study. Patients were randomized 1:1 to receive in the first 28 day cycle, either 5 days of IV-DAC or 5 days of ASTX727, followed by a cross-over to the other in Cycle

2. Cycles 3 forward were with ASTX727. PD were assessed with LINE-1 methylation measured on blood cells at baseline and days 8, 15, 21 and 28 in cycles 1 and 2. Full PK assessments of ASTX727 were performed on Days 1, 2 and 5 with sparse sampling on Days 3 and 4 and on Day 1 of IV-DAC. Modeling of 5 day exposures of ASTX727 and IV-DAC was created for each patient. Safety and clinical response were assessed on all patients.
Results: 50 patients were randomized, of whom 43 had matched PK and 46 had matched PD sample sets for the first 2 cycles. No significant differences were seen when comparing the randomized sequences for any parameters, so all assessments comparing ASTX727 and IV-DAC were performed independent of sequence. The geometric mean maximum demethylation was 9.9% for ASTX727 and 11.2% for IV-DAC [Ratio of oral over IV=0.89, with a lower limit of 90%CI of 0.804]. The geometric mean AUC for IV-DAC was 161 ng*h/mL. The 5 day total geometric mean of the AUC (ng*h/mL) was 769 for ASTX727 and 805 for IV-DAC [(Ratio of oral over IV=0.96, with a lower limit of 90%CI of 0.806]. Decitabine C_{max} was higher for IV-DAC (189 ng/mL) than after ASTX727, Day 2 (109ng/mL) and Day 5 (121ng/mL). The most common adverse events regardless of grade or causality were febrile neutropenia 34%, neutropenia 28%, thrombocytopenia 16%, fatigue 16%, and hypomagnesemia 16%. There were no reported GI Adverse Events greater than Grade 2 with ASTX727 regardless of relationship to treatment.
Summary/Conclusions: Fixed dose oral administration of 35mg decitabine and 100mg E7727 (ASTX727) emulates the AUC of IV-DAC over the 5-day treatment cycle and induces a similar degree of demethylation of LINE-1 sequences in blood cells compared to IV decitabine at 20mg/m^2 dose. The preliminary safety profile is similar to what has been reported for IV-DAC and no increase in GI side effects has been observed. Clinical responses continue to be evaluated as the study data mature. This combination will be tested further as an alternative to parenteral administration of decitabine.

E1193

FACTORS PREDICTIVE FOR INFECTION IN PATIENTS WITH HIGHER- RISK MYELODYSPLASTIC SYNDROMES, CHRONIC MYELOMONOCYTIC LEUKEMIA AND ACUTE MYELOID LEUKEMIA TREATED WITH AZACITIDINE
K. Mądry[1,*], K. Lis[1], J. Żurawska[1], M. Górka[1], P. Kacprzyk[1], M. Dutka[2], M. Rodzaj[3], L. Bołkun[4], D. Krochmalczyk[5], J. Drozd-Sokołowska[1], A. Waszczuk-Gajda[1], W. Knopińska-Posłuszny[6], A. Kopińska[7], E. Subocz[8], A. Masternak[9], R. Guzicka-Kazimierczak[10], L. Gil[11], R. Machowicz[1], J. Dwilewicz-Trojaczek[1]
[1]Hematology, Oncology and Internal Diseases, Medical University, Warsaw, [2]Hematology and Bone Marrow Transplantation, Medical University, Gdańsk, [3]Hematology, Voivodal Specialistic Hospital, Kraków, [4]Hematology, Medical University, Białystok, [5]Hematology, Jagiellonian University, Kraków, [6]Hematology, SP ZOZ WMCO Oncology Center, Olsztyn, [7]Hematology and Bone Marrow Transplantation, Silesian Medical University, Katowice, [8]Hematology and Internal Diseases, Military Institute of Medicine, Warsaw, [9]Hematology, Specialistic Hospital, Opole, [10]Hematology, Pomeranian Medical University, Szczecin, [11]Hematology, Medical University, Poznań, Poland

Background: Hypomethylating agents (HMAs) are the current standard treatment of higher-risk myelodysplastic syndrome (MDS), chronic myelomonocytic leukemia (CMML) and older acute myeloid leukemia (AML) patients. Severe infectious complications are common during HMAs therapy and have been recognized as one of the most important reasons of morbidity and mortality in MDS, CMML and AML patients especially at the beginning of treatment.
Aims: To evaluate the incidence of and predisposing risk factors for infections during the first three azacitidine (AZA) cycles treatment
Methods: In this retrospective study we analyzed 282 consecutive patients with higher- risk MDS (174), CMML (34) and AML with bone marrow blasts <30% (74) treated with azacitidine in 10 Polish hematologic centers between the years 2009-2016. Patients who did not complete three AZA cycles and also did not experience infection were excluded (50 cases).
Results: Median age was 68 (28-93). Median number of AZA cycles was 6 (1-43). Infectious episodes during the first three cycles of AZA were reported in 94 out of 232 (40%) eligible patients - in 32% of MDS, 30% of CMML and 63% of AML patients (p<0.05). Among patients with infection, most of them had their first infection episode during the first cycle -53%, during the second cycle - 29% and during the third AZA cycle -18%. It was found that low neutrophil count (0,6x10^9/Lvs 1,2x10^9/L), low lymphocyte count (1,1x10^9/L *vs* 1,3x10^9/L), low platelet count (37x10^9/L *vs* 63x10^9/L), high blood ferritin level (1101ng/ml *vs* 569 ng/ml), low albumin concentration (3,6 g/dl *vs* 4,0 g/dl), high bone marrow blasts percentage (15% *vs* 12%), higher IPSS, IPSS-R and WPSS score, red blood cell transfusion dependency and worse WHO performance status prior therapy were significantly predictive factors for infection (p<0.05). Factors like age, gender, hemoglobin concentration, iron, immunoglobulin and creatinine blood level, time from diagnosis to beginning of AZA treatment, IPSS and IPSS- R cytogenetics, coexistence of diabetes mellitus, heart failure, chronic obstructive pulmonary disease, second cancer, autoimmune disease and corticosteroids treatment did not have significant impact on infection risk (p>0.05). Antibacterial, antifungal or antiviral prophylaxis did not significantly reduce the risk of infection (p>0.05). Median overall survival patients with infection was 5 months and patients without infection 12 months.
Summary/Conclusions: Patients treated with azaciditine (especially AML patients) are at high risk of infection during the first three AZA cycles. All important infection predictive factors should be assessed before therapy. Patients possessing factors predictive for infection require special approach and predictive infection model should be developed in further analysis.

E1194

OVERALL SURVIVAL, INITIAL TREATMENT AND TREATMENT DURATION OF PATIENTS WITH MYELODYSPLASTIC SYNDROME, A DETAILED POPULATION BASED STUDY
H. Rozema[1,2,*], R. Kibbelaar[2], N. Veeger[2], E. Van Roon[1,2], M. Hoogendoorn[2]
[1]Pharmacotherapy, -Epidemiology & -Economics, University of Groningen, Groningen, [2]Medical Centre Leeuwarden, Leeuwarden, Netherlands

Background: Population-based studies on myelodysplastic syndrome (MDS) containing detailed clinical information of patient characteristics, treatment and follow-up of the disease are scarce. Since 2005, all patients diagnosed with hematological malignancies in Friesland, a province in the Netherlands, are prospectively registered and followed by their clinicians in a population-based registry, the HemoBase. The registry provides representative population-based data on diagnosis, treatment and outcomes in an era where low-intensity treatment such as hypomethylating agents have become available for the elderly.
Aims: The objectives of this study were to determine the overall survival (OS) of patients with MDS and the effect of the variables gender, age, comorbidities, IPSS(-R) score and MDS subtype according to WHO 2016 classification. Furthermore, the leukemia free survival (LFS), the initial treatment and the duration of first-line treatment were analyzed.
Methods: An observational, population-based study was performed using the HemoBase registry. The bone marrow biopsies and aspirates of all MDS patients diagnosed between 01-01-2005 and 31-12-2013 were independently and blindly reviewed by both the hematologist and hemato-pathologist and classified according to the WHO 2016. Treatment categories were defined as intensive chemotherapy (IC) either combined or not combined with allogeneic stem cell transplantation, the hypomethylating agent azacytidine, the immunomodalatory agent lenalidomide, hydroxyurea or best supportive care (BSC) (blood transfusions, erythropoiesis-stimulating agents). Approval was obtained from the Medical Ethics Review Committee from Medical Centre Leeuwarden. Statistical analyses were performed with SPSS 19; survival analyses were presented using Kaplan-Meier estimates.
Results: 217 patients (72.4% male, 66.8% >70 years old, median age 75 years, 27.2% Charlson Comorbidity Index (CCI) score ≥3 at diagnosis) were included with a median follow-up duration of 70.2 months. 15.7% of the population had an IPSS score of ≥1.5 and 12.4% of the population had an IPSS-R score of ≥4.5. In 41.5% no cytogenetic information was available. MDS-RS, MDS-SLD/-MLD, MDS-EB, MDS-U and CMML were diagnosed in 11.5%, 14.7%, 36.4%, 27.2% and 10,1% of the population respectively. 18.4% showed progression towards acute myeloid leukemia (AML). IC, azacytidine, lenalidomide, hydroxyurea and BSC were the initial treatment in 5.1%, 13.8%, 1.4%, 9.7% and 66.4% of the patients respectively. Within 12 months 78.1% of all treated patients terminated their first-line therapy because of death (20.0%), refractory to treatment (18.3%) or disease progression (16.7%). A second treatment was initiated in 10.1% of patients. The median LFS was 18.2 months (95% CI: 12.6-23.8). The median OS of MDS patients in Friesland was 22.5 months (95% CI: 15.2-29.7). Univariate analysis showed an association between lower OS and male gender (HR for women: 0.54, p=0.008, 95% CI: 0.34-0.85), age >80 years (HR: 2.7, p<0.0005, 95% CI: 1.6-4.6), CCI score ≥3 (HR: 2.0, p<0.001, 95% CI: 1.3-3.0), IPSS score ≥1,5 (HR: 2.3, p=0,004, 95% CI: 1.3-4.1), IPSS-R score ≥4,5 (HR: 5.7, p<0.0005, 95% CI: 2.4-2.4) and MDS subtype MDS-EB (HR: 1.8. p=0.016, 95% CI: 1.1-2.9).
Summary/Conclusions: This study provided complete and representative population-based data on overall survival and treatment of patients with MDS in an era of new treatment modalities. Despite the median age of 75 years and significant comorbidity in this population, a third of the patients received treatment in addition to BSC.

E1195

DANAZOL TREATMENT FOR THROMBOCYTOPENIA IN LOWER-RISK MYELODYSPLASTIC SYNDROMES: A REAL LIFE EXPERIENCE
M. Riva[1], E. Ravano[1,*], R. Cairoli[1], A. Molteni[2]
[1]Hematology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milano, [2]Hematology Unit, ASST Cremona, Cremona, Italy

Background: Severe thrombocytopenia is an uncommon event in lower-risk MDS patients, but it may significantly affect the prognosis. In fact, when it occurs, major bleeding may be a life-threatening complication. No licensed pharmacologic approach is nowadays available yet for this unmet need in Europe. Eltrombopag seems to be a very interesting product, but its efficacy and safety still need to be better demonstrated. Even romiplostim could be

suitable, but, at present, its safety is questioned in MDS patients. Furthermore, in clinical practice, danazol, an attenuated androgen, has been reported to have some ability to increase the platelet count in this context (Wattel 1994; Chan 2002).

Aims: To asses efficacy and toxicity of danazol employed to improve severe thrombocytopenia in lower-risk MDS setting.

Methods: We retrospectively reviewed twenty-four patients affected by MDS and treated with danazol for thrombocytopenia. The initial dose was 600mg/day for all patients. The IWG criteria of response (Cheson 2006) were adopted. The outcome was observed every 3 months till 12th month. The overall response rate and the average platelet count or each time of observation were described. Progression free survival was estimated with the Kaplan-Meier product limit method, followed by the logrank test and by the Cox proportional-hazard regression.

Results: Of the 24 patients, 3 patients had a therapy-related MDS. At the starting time of danazol therapy, the IPSS was "low" in 9, "int-1" in 13 and "int-2" in 2 cases respectively; the IPSS-R was "very low" in 2, "low" in 11, "intermediate" in 7 and "high" or "very high" in 4 cases. At baseline in 14 patients the platelet count was lower than 20x10^3/mL, the average was 20x10^3/mL and the maximum value was 38x10^3/mL. The median dose was 600mg (range 200-600) also maintained at least up to 3 months (range 400-600). At 6 and 12 months the median dose therapy was 400mg (range 400-600 and 200-600 respectively). The response rate was 79.1% (19 responders on 24 treated). The average count increased as shown in Figure 1, over 60x10^3/mL after 6 months from the beginning of therapy and so maintained after one year. Only 3 patients lost the response at 187, 600 and 633 days respectively. The median survival was not reached in the presented series, and the probability to maintain the response is over 75% after two years from the beginning therapy in the responder patients (Figure 2). Adverse events recorded were as follows: moderate (grade 1 and 2) increase in transaminases in 4 cases (with reduction of danazolo to 400mg/day in 2 of these); 1 case of severe but reversible liver toxicity (grade 3) (with subsequently drug suspension); severe (grade 3) but reversible renal failure in 1 case (the drug was stopped); moderate (grade 1 and 2) increasing of serum creatinine in 6 case (with reduction of danazolo to 400mg/day in 2 of these); reversible cutaneous rush in 3 cases; amenorrhea in 1 case (the only fertile woman in the series); weight loss and loss of appetite in 1 case, weight gain in 1 case.

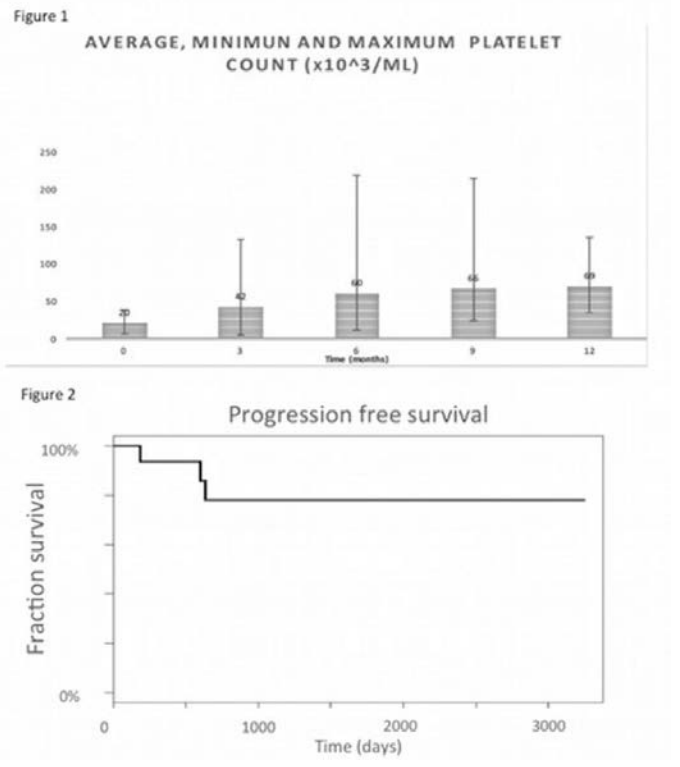

Figure 1.

Summary/Conclusions: This series confirms the efficacy of danazol to improve platelet count in the most of patients with severe thrombocytopenia due to lower-risk MDS. In all patients with increased platelet count, the response was clinically significant. The median dose of 600mg should be maintained for at least 3 months to properly assess the effectiveness of therapy and then adjusted according to response and toxicity. The response may not be immediate, but seem to be reachable after 3-6 months of treatment. A responsive patients have short probability to loss the response, that may last for very long time. The toxicity profile of this drug is low. The mechanism of action of danazol in MDS patients remains unclear. Waiting for more information on the efficacy and safety of eltrombopag from the clinical trials in progress, danazol may be a good therapeutic option for these patients.

E1196

TREATMENT PATTERNS IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell[1,*], A. Galaznik[1], E. Farrelly[2], M. Blazer[2], H.-C. Shih[2], A. Raju[2], A. Ogbonnaya[2], M. Eaddy[2], R. Fram[1], D. Faller[1]

[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Xcenda, Palm Harbor, United States

Background: Treatment of patients with HR-MDS includes hypomethylating agents (HMAs) (azacitidine and decitabine), high-intensity induction chemotherapy (IC), and stem cell transplant (SCT). Given the rarity of disease, information available on how these treatments are applied in practice is limited.

Aims: We evaluated the treatment patterns of HR-MDS patients engaged in routine care within the US.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old were retrospectively identified from Optum, a large US claims database between 1/1/2008 and 10/31/2015. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with an HR-MDS ICD-9/10 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: absence of continuous enrollment in medical and pharmacy benefits for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during the baseline period. First-line therapy (1LT) was defined as an MDS-specific treatment (as defined by NCCN MDS Guidelines v2.2017)[1] initiated on or after the index date. Patients were followed until death, end of continuous enrollment, or end of study (12/31/2015). For patients with progression to acute myeloid leukemia (AML), treatment pattern evaluation stopped at AML diagnosis.

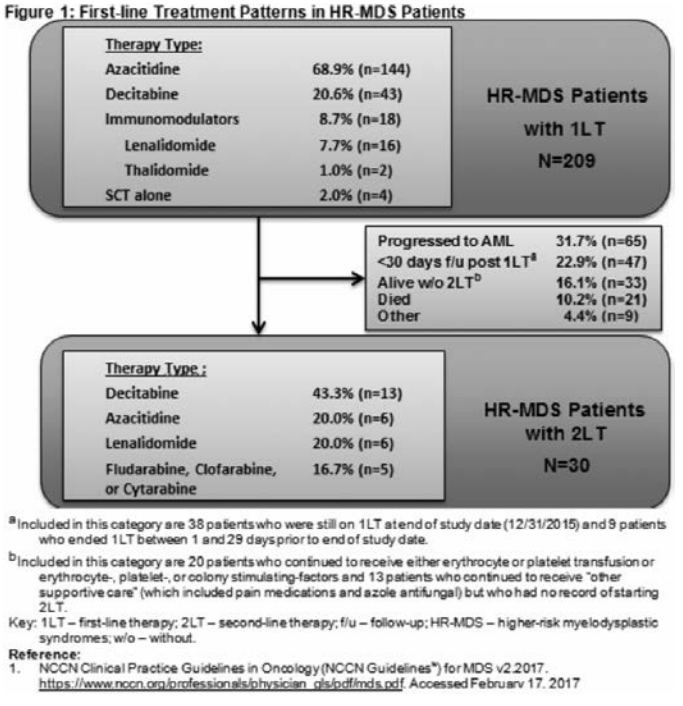

Figure 1.

Results: 335 newly diagnosed HR-MDS patients were identified; 209 (62.4%) were treated with 1LT with treatment initiated within 1 month of diagnosis (median: 17 days, interquartile range [IQR]: 9, 35). A higher proportion of untreated patients (n=126) was ≥75 years of age (71.4% *vs* 53.1%) and had certain comorbidities at baseline (congestive heart failure, 23.0% *vs* 16.3%; renal disease, 24.6% *vs* 16.3%; diabetes 31.0% *vs* 23.4%, diabetes with end organ failure, 16.7% *vs* 8.1%) than treated patients. For treated patients, 1LT with azacitidine predominated in 68.9% of patients (n=144), followed by decitabine in 20.6% of patients (n=43), and immunomodulators (lenalidomide or thalidomide) in 8.7% of patients (n=18) (Figure 1). 4 patients had only SCT and an additional 14 had SCT at some point during follow-up. With regard to HMA therapy, median duration was 4.5 months (IQR: 2.6, 9.5) for azacitidine and 4.8 months (IQR: 2.1, 11.6) for decitabine. A greater proportion of decitabine-treated patients

received supportive care with colony-stimulating factors (CSFs) (39.5% *vs* 28.5%) and either erythrocyte or platelet transfusions (69.8% *vs* 57.6%) during 1LT *vs* azacitidine-treated patients. Second-line therapy (2LT) was administered to 30 (14.4%) patients; the HMAs again predominated in 63.3% of patients (n=19). Of patients not receiving 2LT, 65 (31.7%) progressed to AML, 47 (22.9%) had <30 days of follow-up due to proximity to end of study (38 [80.9%] of these were on 1LT at end of study date), 33 (16.1%) continued to receive some supportive care and, 21 (10.2%) died.

Summary/Conclusions: Most HR-MDS patients treated in routine care are treated according to guidelines, with the HMA, azacitidine, predominating. Underlying comorbidities and older age may influence whether or not to treat HR-MDS patients with 1LT. For treated HR-MDS patients, duration of 1LT did not differ with azacitidine and decitabine. However, use of certain MDS-related supportive care treatments varied by choice of HMA, with more decitabine-treated patients receiving CSFs and transfusions. Further research is needed to determine how these factors influence both clinical outcomes in a HR-MDS population.

E1197

APPRECI8: A PIPELINE FOR PRECISE VARIANT CALLING INTEGRATING 8 TOOLS

S. Sandmann[1,*], M. Karimi[2], A. de Graaf[3], B. van der Reijden[3], E. Hellström-Lindberg[2], J. Jansen[3], M. Dugas[1]
[1]Institute of Medical Informatics, University of Münster, Münster, Germany, [2]Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, [3]Laboratory Hematology, RadboudUMC, Nijmegen, Netherlands

Background: For the use of next-generation sequencing in clinical routine valid variant calling results are crucial. However, evaluation of eight open-source variant calling tools on two different real- and simulated data sets has pointed out that variant calling - even of single nucleotide variants and short indels - remains challenging. Perfect results could not be obtained with any of the considered tools. High sensitivity was always accompanied by low positive predictive value (PPV).

Aims: We aimed at developing a variant calling pipeline with both, high sensitivity and high PPV.

Methods: We developed *appreci8*, a variant calling pipeline combining the output of eight open-source variant calling tools: GATK HaplotypeCaller, Platypus, VarScan, LoFreq, FreeBayes, SNVer, SAMtools and VarDict. The pipeline performs several steps of filtration, including a final automatic characterization of all reported calls as artifacts, likely polymorphisms and likely mutations. To train our pipeline, we analyzed two data sets covering data of 54 myelodysplastic syndrome (MDS) patients, sequenced on Illumina HiSeq, and 111 MDS patients, sequenced on Illumina NextSeq. Subsequently, two independent test sets were analyzed. The first test set covered 237 MDS patients, sequenced on Illumina HiSeq. The second test set covered 89 MDS patients, sequenced on Roche 454. In all cases the same target region consisting of 19 genes (42,322bp) was analyzed. Validation was performed by re-sequencing on the same platform, on a different platform and expert-based review.

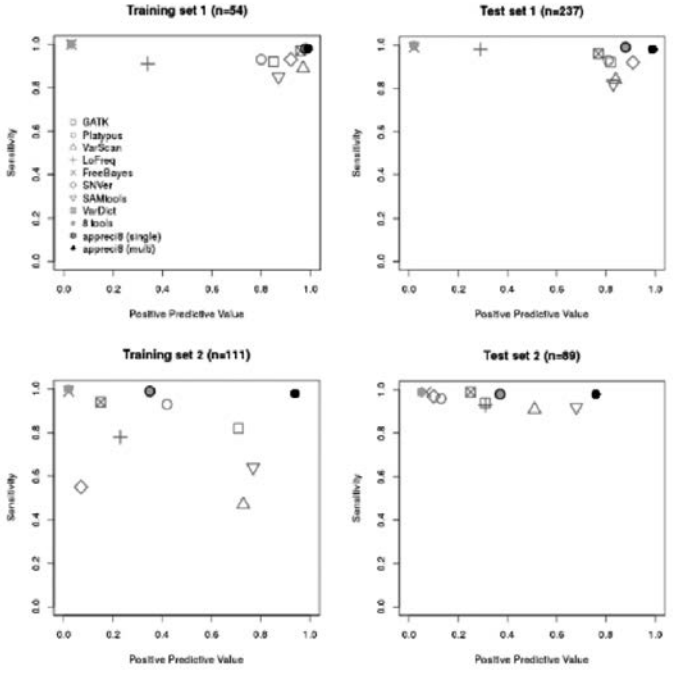

Figure 1.

Results: When analyzing the training sets with only one of the eight variant calling tools and considering all variants -pathogenic as well as polymorphisms-, sensitivity ranges between 0.85 and 1.00 in case of set 1 and 0.47 and 0.99 in case of set 2. Although FreeBayes features highest sensitivity regarding both sets, it consistently features lowest PPV as well (set 1: 0.03, set 2: 0.02). Combining the output of all variant calling tools leads to perfect sensitivity, while PPV is 0.03 for set 1 and 0.02 for set 2. Application of our *appreci8* pipeline leads to a minor decrease in sensitivity (set 1 and set 2: 0.98), while PPV is significantly increased (set 1: 0.99, set 2: 0.94). The PPV of the *appreci8* output for both training sets is higher compared to each of the individual tools. Analysis of the independent test set 1 leads to comparable results. Sensitivity of the individual tools ranges between 0.82 and 0.99, while PPV ranges between 0.02 and 0.91. Combining the output of all variant calling tools leads to sensitivity of 1.00 and PPV of 0.02. However, application of *appreci8* leads to variant calling results with sensitivity of 0.98 and PPV of 0.99. To test the robustness of our approach, we analyzed Roche 454 data, although the pipeline was exclusively trained on Illumina data. Regarding the individual tools sensitivity ranges between 0.91 and 0.99, while PPV ranges between 0.07 and 0.68. By combining the output of all variant calling tools, sensitivity increases to 0.99, while PPV is 0.05. Application of *appreci8* leads to sensitivity of 0.98 and PPV of 0.76.

Summary/Conclusions: To consider variant calling results in clinical routine, it does not seem appropriate to rely on the output of a single tool only. Instead, combining the output of several tools and applying a set of filters as it is done by our appreci8 pipeline leads to results with both high sensitivity and PPV. Nonetheless, variant calling results should, especially at allelic frequencies below 20%, always be viewed with criticism.

E1198

COMPARISON OF ADMINISTRATION OF HYPOMETHYLATING AGENTS WITH EFFICIENCY OF ALLOGENEIC SCT IN ELDERLY PATIENTS WITH ADVANCED MDS

J. Cermak[1,*], A. Vitek[1], J. Maalouf-Soukupova[1], M. Markova-Štastna[1], P. Cetkovsky[1]
[1]Clinical Hematology, Institute of Hematology and Blood Transfusion, Praha, Czech Republic

Background: Hypomethylating agents (HMA) have been introduced as a promising agent in the treatment of elderly patients with advanced myelodysplastic syndromes (MDS) leading to a response in approximately 50% of patients. However, most of the patients relapse and estimated years survival is below 10%. Stem cell transplantation (SCT) still represents the only curative treatment even in elderly patients with advanced MDS and it is connected with long-term survival in 35-40% despite relatively high risk of transplant related mortality (25-30%).

Aims: The aim of the study was a retrospective analysis of results of the treatment of 59 elderly patients (50 years of age or older) with MDS RAEB-2 or with acute myeloid leukemia with multilineage dysplasia with less than 30% of bone marrow blasts (MDS RAEB-T according to the FAB classification) who received either HMA or underwent allogeneic SCT.

Methods: In the HMA group, 34 out of total 38 patients received azacytidine (Vidaza®) in the dose of 75mg/m^{2}x7 every 28 days and 4 patients were treated with decitabine (Dacogen®) in the dose of 20mg/m^2 x5 every 28 days. Median number of cycles administered was 10.4 (range 3-31). An age and diagnosis matched transplanted group consisted of 21 patients, 9 patients were transplanted upfront, 12 patients were pretretated either with combination chemotherapy (10 patients) or with HMA (2 patients) and achieved CR prior to SCT. Ten patients received myeloablative conditioning and 11 patients were transplanted after reduced conditioning regimen.

Results: A hematologic response to HMA (CR,PR, hematologic improvement) was observed in 22 out of 38 patients in HMA group (57.9%), CR was achieved in 10 patients (31.8%). In SCT group, engraftment was reached in 20 out of 21 patients, 11 patients died after SCT (6 on complications related to SCT, 5 patients relapsed). No difference was observed between both the groups in 2 years estimated overall survival (OS), (42% for SCT *vs* 36% for HMA), a significant difference in favour of SCT was present in estimated 3 years and 5 years OS (42% and 38% for SCT *vs* 9% and 4% in HMA group, P=0.001). Median OS was 18.7 months in HMA treated group compared to 42.6 months in SCT group (P=0.02). In a recent analysis performed at 48 months after starting the treatment, 2 patients treated with HMA (5,3%) and 9 transplanted patients (42.8%) were alive, 23 patients in HMA group and 6 patients in SCT group relapsed. No significant differences in results and adverse effects of treatment were observed between patients aged 50-60 years and those older than 60 years in both HMA and SCT groups.

Summary/Conclusions: Our results confirm previous observations showing that despite a promising effect of HMA resulting in hematologic response in more than 50% of elderly patients with advanced MDS, allogeneic SCT still represents the only potentially curative treatment connected with long-term survival in a significant number of patients even in elderly MDS patients.

E1199

A MULTICENTER, OPEN-LABEL, PHASE I CLINICAL STUDY: SAFETY, EFFICACY, AND PHARMACOKINETICS OF ORAL RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES

K. Ishizawa[12,*], K. Usuki[3], K. Ando[4], Y. Ueda[5], T. Kiguchi[6], N. Uike[78], Y. Onishi[2], H. Iida[9]
[1]Hematology and Cell Therapy, Yamagata University Faculty of Medicine, Yamagata, [2]Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, [3]Department of Hematology, NTT Medical Center Tokyo, Tokyo, [4]Department of Hematology and Oncology, Tokai University School of Medicine, Isehara, [5]Department of Hematology/Oncology, Kurashiki Central Hospital, Kurashiki, [6]Department of Hematology, Chugoku Central Hospital, Fukuyama, [7]Department of Palliative Care Medicine, Saga Medical Center Koseikan, Saga, [8]Department of Hematology, National Hospital Organization Kyushu Cancer Center, Fukuoka, [9]Department of Hematology, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Rigosertib, a novel phosphoinositide 3 kinase pathway inhibitor, induces G2/M arrest leading to the apoptosis of cancer cells and myeloblasts and is safe for and well tolerated by pts with low, intermediate-1, intermediate-2, or high-risk myelodysplastic syndromes (MDS).
Aims: The aims of the study were to assess the safety, efficacy, and pharmacokinetics of oral rigosertib and to determine the recommended dose (RD) for a Phase II clinical study in Japanese pts with recurrent/relapsed or refractory MDS.
Methods: We conducted a multicenter, open-label, Phase I clinical study of oral rigosertib. The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age: 20 or older; ECOG PS of 0 to 2; and no major organ dysfunctions. Rigosertib (280 and 560mg BID) was administered orally in one 21-day cycle (up to cycle 6) that consisted of the 14-day, twice-daily, oral administration term, followed by 7-day monitoring. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results, 2) efficacy as assessed with the International Working Group 2006 criteria, and 3) pharmacokinetics.
Results: Between March 2013 and November 2014, 6 male and 3 female pts (median age: 70; range 52-80) were enrolled. ECOG PS was 0 in 7 pts and was 1 in 2 pts, and 3 and 6 pts were eventually assigned to the 280 and 560mg BID arms, respectively. According to the FAB classification, 4, 2, 2, and 1 pts were categorized to RAEB, RARS, RA, and RAEB-t, respectively. The prognostic factor according to IPSS was Int-1 risk in 4 pts (1 and 3 pts in the 280 and 560mg BID arms, respectively) and was Int-2 in 5 pts (2 and 3 pts in the 280 and 560mg BID arms, respectively). DLT occurred in 1 pt in the 280mg BID arm and in 2 pts in the 560mg BID arm: the former consisted of type 2 diabetes and grade 4 delirium, and the latter grade 5 urinary tract infection and grade 3 prolonged QT interval. Therefore, the RD for a Phase II clinical study in Japanese pts was determined to be 560mg BID. On day 11 of treatment, 1 pt in the 560mg BID arm died of grade 5 urinary infection whose relationship with the investigational drug was rated to “Definite”. The presumed cause of death for this patient was septic shock caused by urinary tract infection. The mean counts of leukocytes, neutrophils, lymphocytes, and reticulocytes in the 280mg BID arm did not decrease along with increases in the number of cycles delivered but decreased slightly in the 560mg BID arm. Any changes of note were not found in other hematological items. One case of grade 3 neutropenia developed in the 280mg BID arm, and 1 case each of grade 3 laboratory abnormalities—increased alanine aminotransferase, increased aspartate aminotransferase, prolonged QT interval, neutropenia, and decreased hemoglobin—occurred in the 560 BID arm. The hematological remission rate was 11.1% (1 marrow CR; 1/9 pts), and the hematological improvement rate was 11.1% (1 HI-P; 1/9 pts). Among the PK parameters, inter-individual variability was observed in the C_{max} and AUC. However, changes suggesting the accumulation of rigosertib during repeated oral administration (e.g., consistent increases in the C_{max} and AUC) were not found.
Summary/Conclusions: The present chemotherapy regimen of oral rigosertib was well tolerated. Our study indicates that the RD for a Phase II clinical study is 560mg BID in Japanese patients with recurrent/relapsed or refractory MDS.

NON-OVERLAPPING PROMOTER AND SUPERENHANCER DRIVEN PROCESSES SUPPORT MYELOMA CELL GROWTH AND SURVIVAL VIA DISTINCT REGULATORY AXES

M. Fulciniti[1,*], C. Lin[2], M. Samur[1], H. Avet-Loiseau[3], K. Anderson[1], J. Bradner[4], N. Munshi[1]
[1]Dana Farber Cancer Institute, Boston, [2]Baylor college of medicine, Houston, United States, [3]Cancer research center, Toulouse, France, [4]Novartis, Boston, United States

Background: We have previously reported that E2F1 and its heterodimerization partner DP1 promote MM tumor proliferation both *in vitro* and in vivo; and observed an inverse correlation between their expression and patient survival suggesting a role in MM pathogenesis. Moreover, E2F functional impairment by a dimerization inhibiting stapled peptide significantly affects myeloma tumor cell growth while sparing effect on normal components of bone marrow as well as normal plasma cells, suggesting an E2F dependency in MM cells.
Aims: In this study, our aim was to defined the regolatory landscape of E2F in MM to better understand how E2F1 and DP1 drive myeloma cell proliferation; and to define the relationship between promoter proximal transcription factor-associated gene expression and super-enhancer-driven transcriptional programs.
Methods: We integrated genetic perturbation with functional omics to define E2F role in MM. Global occupancy of E2F1 and DP1 in MM was evaluated by ChIP-seq analysis. E2F1 and DP1 genomic localizations were then integrated to MM reference epigenome. Enhancers and super-enhancers were mapped using ROSE2 (github.com/bradnerlab/pipeline). Read densities were calculated using bamliquidator (github.com/BradnerLab/pipeline/wiki/bamliquidator).
Results: Integration of E2F1 and DP1 genomic localization to MM reference epigenome revealed specific co-occupancy of the factors at promoters of active genes marked by H3K4me3, with a strong positive correlation between E2F and RNA Polymerase II (RNA Pol II) binding at transcription start sites. In contrast, active enhancers, as defined by promoter distal Mediator (MED1) peaks and marked by H3K27ac and BRD4, showed virtually no E2F binding. Prompt by these observations, we explored the transcriptional and functional interrelationship between E2F and BETs to identify their individual contribution to eventual functional effect in MM. Unbiased hierarchical clustering revealed distinct regulatory axes for E2F and BETs, with E2F predominantly localized to active gene promoters of growth/proliferation genes and BETs disproportionately at enhancer- regulated tissue specific genes confirming that these factors establish distinct target gene programs. At the extremes, we found less than 10% of genes were among the top 500 in BRD4 enhancer signal (*i.e.* SE-regulated) and top 500 E2F promoter signal. We hypothesized that the presence of BETs and E2F in distinct regulatory axes divides active genes in MM into those that can be selectively influenced by BET inhibition or E2F perturbation, but not both. In line with this we have observed that dual E2F and BET inhibition is synergistic for MM cell growth, both *in vitro* and in vivo.
Summary/Conclusions: In conclusions, our results highlight the existence of non-overlapping promoter and super-enhancer-associated dependencies in multiple myeloma, suggesting a sequestered molecular control that may be perturbed in cancer with potential for development of a promising therapeutic strategy.

Background: In multiple myeloma (MM), next generation sequencing (NGS) has expanded our knowledge of genomic lesions, and highlighted a dynamic and heterogeneous composition. Despite a growing number of cases sequenced, the full potential of NGS studies has not been exploited so far.

Aims: We used a custom target pulldown (TPD) approach on a large cohort of MM samples at diagnosis, with homogeneous treatment and long follow-up, to further our understanding of the landscape of driver lesions in MM and how this can be used to improve prognostication and disease classification.
Methods: We used a custom-designed SureSelect pulldown strategy (Agilent Biotechnologies) to target 246 genes implicated in MM or cancer in general; 2538 single nucleotide polymorphisms; the immunoglobulin heavy chain (IGH) locus. We sequenced unmatched DNA from CD138-purified plasma cells from 418 patients with a median follow-up of 5.4 years using Illumina Hiseq2000 machines. We applied algorithms developed in-house to detect driver genomic events, filtering out potential artifacts and germline variants. We then ranked each mutation on its likelihood of being oncogenic.
Results: We identified 197 driver events including gene mutations, aneuploidies and IGH translocations (IGH-Tx), median of 6 per patient. Gene mutations where found in >99% of patients. At least one oncogenic mutation of a known driver gene previously identified (*KRAS, NRAS, TP53, FAM46C, BRAF, DIS3, TRAF3, SP140, IRF4*) was found in 64%, with a long tail of infrequently mutated genes with uncertain significance. Karyotypic class was assigned in 80% of patients, with 9% of hyperdiploid cases also showing an IGH-Tx (mostly t(4;14)). IGH-Tx and aneuploidies dominated the MM genomic landscape, KRAS and NRAS being the only point mutations present in the 15 most frequent driver events. Multivariate analysis by sparse Cox regression highlighted only four driver events with significant prognostic impact for both progression-free (PFS) and overall survival (OS): t(4;14) (HR 1.88, CI 1.25-1.84), amp(1q) (HR2.63, CI 1.92-3.59), del(17p) (HR2.55, CI 1.66-3.92), and rare mutations of *ATP13A4* (HR 0.08, CI 0.01-0.65, mutated in 1.4% of patients). We found a significantly worse prognosis for increasing numbers of driver lesions in each patient (median OS 8.2 *vs* 3.5 years for <5 and>8 driver events, respectively). This was only partially explained by instances of additive effect or interactions between variables, which were very informative but not frequent. To better investigate these findings in the context of the genomic landscape of each case, we applied Bayesian clustering algorithms. The large number of driver events screened led to the identification of three groups: in the largest one, some hyperdiploid and IGH-Tx cases clustered together, suggesting that secondary mutations and CNAs required for tumor progression are often shared between these two subgroups. We then identified two clusters both characterized by significantly lower number of mutations, but with opposing features. One was enriched for IGH-Tx, had the highest number of CNAs overall, showed higher prevalence of amp(1q), del(13), del(17p), *TP53* mutations, and had a shorter median OS of 5.3 years. The other was mostly composed of hyperdiploid cases and showed fewest CNAs and mutations, with a good prognosis (median OS not reached).

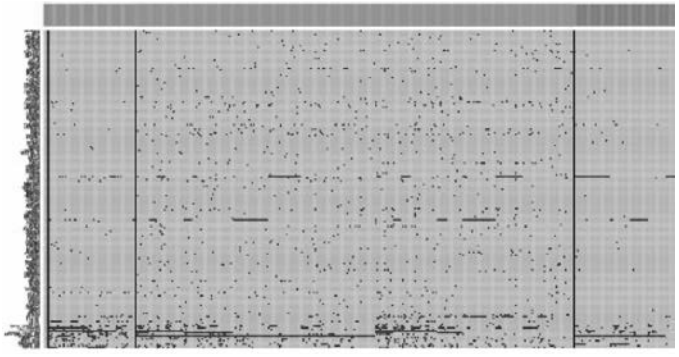

Figure 1.

Summary/Conclusions: We report on the first attempt towards the use of extended tumor genotype for a genomic classification of MM using innovative clustering algorithms. Despite the heterogeneity of the disease, we could identify disease subgroups with a distinct spectrum and number of driver events carrying different prognosis, supporting the introduction of genomics in the clinical approach to MM

A NOVEL METHOD FOR GENOME-WIDE COPY NUMBER ASSESSMENT FROM TARGETED SEQUENCING DATA AND CLINICAL APPLICATION IN PATIENTS WITH MULTIPLE MYELOMA

G. Ryland[1,*], J. Markham[2], K. Jones[1], E. Aydogan[1], T. Papenfuss[2], M. Chin[3], J. Sive[4], K. Yong[3], M. Prince[5], D. Westerman[1], M. Dickinson[5], P. Blombery[1]
[1]Pathology, [2]Research, Peter MacCallum Cancer Centre, Melbourne, Australia, [3]UCL Cancer Institute, [4]Department of Haemato-Oncology, St Bartholomew's Hospital, London, United Kingdom, [5]Haematology, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Assessment of gene mutations by next generation sequencing is now standard in patients with haematological malignancy. However, larger chromosomal aberrations (e.g. exon, gene and chromosome level gains and losses) also serve as critical prognostic indicators that guide therapeutic decision making. These larger genetic lesions are typically detected using a separate methodology such as conventional cytogenetics/FISH.
Aims: We aimed to develop and clinically validate a novel method for assessing genome-wide copy number changes using an existing hybridisation-based targeted sequencing panel in order to provide further critical prognostic information in addition to variant-level data without the need for a separate assay.
Methods: A custom Agilent SureSelect capture panel targeting 313 genes of relevance in myeloid and lymphoid malignancies was sequenced on an Illumina NextSeq (paired end 75bp reads) to a mean depth of 700x. An in-house bioinformatics pipeline was created to analyse probe counts from on-target and off-target reads, which also corrects for biases introduced during DNA enrichment and sequencing by normalisation to a pooled reference comprising 10 normal controls. Three metrics for copy number calling were tested including a per-mutation-based statistic from circular binary segmentation, weighted mean and variance for the bins in each segmented region, and an MLPA-like test using read count ratios compared to controls. An interactive web-based graphical user interface was developed to visualise both large-scale and exon level amplification and deletions.
Results: We validated the approach on 45 samples from patients with multiple myeloma (predominantly advanced disease) with known copy number status as determined by conventional cytogenetics, FISH and MLPA. Our novel method detected numerous copy number changes that were outside the targeted region (through genome-wide mapping and analysis of off-target reads) such as del(1p) in 12 patients, gain(1q) in 15 patients and MYC amplification in 5 patients. Moreover our method was able to interrogate and resolve the complexity of changes on del(1p) including isolated deletions of FAM46C, CDKN2C and FAF1. Of 25 patients with a TP53 mutation, 20 had concomitant del(17p) detected by our assay, while 1 case had a del(17p) without mutation; both monoallelic and biallelic TP53 aberration was associated with poor survival. Other findings in this cohort include frequent DIS3 mutations in patients with monosomy 13 and novel oncogenic copy number changes such as the high level amplification of KRAS in 1 case.
Summary/Conclusions: We have developed and demonstrated utility of a reliable workflow for genome-wide copy number assessment that can be implemented using existing targeted short read sequencing data, greatly extending the utility of this technology beyond the identification of mutations in patients with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.

THE MULTIPLE MYELOMA GENOME PROJECT: DEVELOPMENT OF A MOLECULAR SEGMENTATION STRATEGY FOR RISK STRATIFICATION OF MULTIPLE MYELOMA

K. Mavrommatis[1], B. Walker[2], M. Samur[3], F. Towfic[4], C. Ashby[2], C. Wardell[2], M. Bauer[2], M. Ortiz[5], E. Flynt[4], Z. Yu[4], M. Amatangelo[4], M. Trotter[5], H. Avet-Loiseau[6], G. Jackson[7], K. Anderson[3], A. Thakurta[4], N. Munshi[3], G. Morgan[2,*]
[1]Celgene Corporation, San Francisco, [2]Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, [3]Dana Farber Cancer Institute, Harvard Medical School, Boston, [4]Celgene Corporation, Summit, United States, [5]Celgene Corporation, Seville, Spain, [6]Centre de Recherche en Cancérologie de Toulouse Institut National de la Santé et de la Recherche Médicale, Toulousse, France, [7]Newcastle University, Newcastle, United Kingdom

Background: Segmenting multiple myeloma (MM) into subgroups with distinct pathogenesis and clinical behavior is critical to implement a targeted therapy approach and improve prognosis for patients. Current technologies have elucidated major translocation groups and recurrent copy number changes with varying effects on prognosis. However, minor translocation and mutational groups remain poorly described due to limited sample numbers and small datasets. The availability of multiple sets of high quality genomic data associated with clinical information, cytogenetics, and outcomes provides an opportunity to create an integrative genomic predictor using mutational, chromosomal, and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.
Aims: The Multiple Myeloma Genome Project (MGP) is a global collaborative research initiative that aims to develop a molecular segmentation strategy for MM to inform development and deployment of clinically relevant tests that could improve diagnosis, prognosis, and treatment of patients with MM.
Methods: We have established a dataset representing 1766 MM patients for which whole exome sequencing (WES; n=1367), Whole Genome Sequencing (WGS; n=779), and expression data from RNA-Seq and Expression arrays (n=1059) were available. Data were derived from the Myeloma XI trial, Dana-Faber Cancer Institute/Intergroupe Francophone du Myeloma, The UAMS Myeloma Institute and the Multiple Myeloma Research Foundation (IA1 – IA9). Data were investigated for genetic abnormalities following preprocessing with state of the art methods and algorithms.
Results: Our analysis is focused on data from newly-diagnosed MM patients (n=1751), which is the majority of our dataset. We have begun to integrate genomic dataset with various correlates. Based on our data, we have at least

80% power to detect gene expression changes and genomic variants associated in >2% of the study population. WES data identified the main cytogenetic groups, somatic variants, and significantly mutated genes. 28 significantly mutated genes were present in newly diagnosed samples (17 genes in >2% of samples). The main recurrent mutations included *KRAS* and *NRAS*, and negative regulators of the NF-κB pathway; however, novel genes were also identified. Distinct mutational patterns, proportions, and sites between translocation subgroups were found and will be presented. In addition, we detected recurrent copy number abnormalities and examined the interaction with mutations and fusion gene expression from RNASeq. Preliminary analysis with an integrative model developed with machine learning methods/approaches using CN, SNV and structural variants predicted a subset of high-risk patients. Unsupervised molecular classification is in progress to integrate genomic data and define subgroups, which will be presented.

Summary/Conclusions: We have established the largest repository of molecular profiling data in MM associated with clinical outcomes. Integrated analyses are enabling generation of clinically meaningful disease segments associated with differing risk that will inform development of clinical tests. ThemgP intends to build a global network by expanding collaboration with global MM centers to incorporate additional datasets through current and new collaborations.

ALVOCIDIB SYNERGIZES WITH VENETOCLAX IN PRECLINICAL MODELS OF MULTIPLE MYELOMA

H. Haws[1], M. Livingston[1], W. Kim[1], R. Mangelson[1], P. Peterson[1], C. Whatcott[1,*], A. Siddiqui-Jain[1], S. Weitman[1], D. Bearss[1], S. Warner[1]
[1]Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: With over 30,000 new cases expected in 2016 (US), new treatments are desperately needed for the treatment of multiple myeloma (MM). Major developments in the treatment of MM have included introduction of agents such as lenalidomide, thalidomide, or bortezomib. Bortezomib, an inhibitor of the proteasome, reduces the degradation of many proteins, including the pro-apoptotic protein NOXA. However, high levels of MCL-1 and/or low basal levels of NOXA have been implicated in bortezomib resistance and negative patient outcomes. The BCL-2-specific BH3 mimetic, venetoclax (ABT-199), is also being explored in multiple hematologic malignancies, including multiple myeloma. However, intrinsic resistance to venetoclax treatment observed in MM patient samples has been attributed to a low BCL-2-to-MCL-1 gene expression ratio, suggesting a central role for MCL-1 in cell survival in this context as well. NOXA functions to sequester the anti-apoptotic BCL-2 family member, MCL-1. Increased MCL-1 expression is a known resistance mechanism to venetoclax treatment in a variety of cell types including chronic lymphocytic leukemia and lymphomas. Considering the central role of MCL-1 to treatment efficacy in MM, we investigated the ability of an MCL-1-lowering agent, namely the CDK9 inhibitor alvocidib, to potentiate the activity of venetoclax in MM. Alvocidib suppresses MCL-1 expression via CDK9-mediated regulation of RNA polymerase II. Alvocidib has demonstrated robust improvements in the clinical response rates of high-risk, newly diagnosed acute myeloid leukemia (AML) patients as part of the time-sequential ACM regimen (alvocidib + cytarabine + mitoxantrone).

Aims: We hypothesize that alvocidib would potentiate the activity of venetoclax in MM through an MCL-1-dependent mechanism.

Methods: CellTiter-Glo and Caspase-Glo were used for cell viability and apoptosis assays interrogating alvocidib and venetoclax in cell lines. We performed RT-PCR to measure mRNA levels of MCL-1 and other genes following treatment. Protein levels were interrogated using standard immunoblotting techniques. To determine the efficacy of an alvocidib/venetoclax combination on tumor growth *in vivo*, we performed a mouse study in the OPM-2 xenograft model.

Results: In this report, we demonstrate that alvocidib inhibited the protein expression of MCL-1 in MM cells in a time-dependent fashion, up to 96 hours. In cell viability assays, the addition of up to 100 nM venetoclax resulted in a 2.8-fold reduction in the IC_{50} of alvocidib in the cultured OPM-2 cell line. Conversely, the potentiation of venetoclax activity with the addition of alvocidib resulted in a more than 500-fold decrease in IC_{50} in the relatively venetoclax-resistant OPM-2 cells. Additional studies are currently underway to investigate the efficacy of alvocidib and venetoclax in the context of bortezomib resistance where low NOXA may contribute to enhanced cell survival via MCL-1.

Summary/Conclusions: Taken together, our data suggest that the combination of alvocidib with venetoclax may constitute a novel therapeutic regimen in the treatment of MM. Further, it suggests that CDK9-mediated targeting of MCL-1 may offer a clinical route to addressing intrinsic resistance in MM patients.

NOVEL COMPOUND, OSSL_325096, INDUCES APOPTOSIS IN MULTIPLE MYELOMA CELLS THROUGH VCP INHIBITION

N. Nishimura[1,*], M.O. Radwan[2,3], M. Amano[1], S. Endo[1], S. Ueno[1], N. Ueno[1], H. Tatetsu[1], H. Hata[4], Y. Okamoto[2], M. Matsuoka[1], M. Otsuka[2], Y. Okuno[1]
[1]Department of Hematology, [2]Department of Bioorganic Medicinal Chemistry, School of Pharmacy, Kumamoto University, Kumamoto, Japan, [3]Department of Chemistry of Natural Compounds, National Research Center, Cairo, Egypt, [4]Graduate School of Health Sciences, Kumamoto University, Kumamoto, Japan

Background: VCP (p97) is an ER-associated protein that belongs to the AAA ATPase family. It has a variety of cellular functions including ER-associated protein degradation, autophagy, and aggresome formation. Recent studies have elucidated emerging roles of VCP and its potential as a therapeutic target in several cancer subtypes including multiple myeloma (MM).

Aims: We screened approximately 2,000 small molecular compounds to find out novel small compounds that suppress growth of MM cell lines, and found that OSSL_325096 has strong anti-proliferative activity on MM cell lines (IC50 100-500nM). In this study, we evaluated anti-MM activity of OSSL_325096 through VCP inhibition, in an ATP-competitive manner.

Methods: OSSL_325096 were purchased from Princeton BioMolecular Research, Inc. (Princeton, NJ, USA). His-tagged human *VCP* (*hVCP*) cDNA was cloned and utilized to generate hVCP protein *in vitro* as previously described [Chou *et al., PNAS,* 2011, vol. 108(12): 4834-4839] to evaluate the VCP inhibition by OSSL_325096. For *in vivo* analysis, MM xenograft model mice were intraperitoneally administrated with vehicle or 50mg/kg of OSSL_325096 twice a week.

Results: OSSL_325096 inhibited proliferation of MM cell lines, including one bortezomib-resistant cell line (Figure 1). OSSL_325096 induces apoptosis in these MM cell lines and primary MM cells purified from patients but not in PBMCs from healthy donors. OSSL_325096 treatment leads to accumulation of poly-ubiquitinated proteins, cleavage of caspase-3, and up-regulation of CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-mediated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical structure similar to several known VCP inhibitors. Therefore, to evaluate the role of VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of VCP induced apoptosis in MM cell lines, accompanied with accumulation of poly-ubiquitinated protein. In-silico protein-drug binding simulation suggests possible binding of OSSL_325096 to the ATP binding site in VCP's D2 domain. Indeed, in the cell-free ATPase assay, OSSL_325096 showed dose-dependent inhibition of VCP's ATPase activity (Figure 3). The IC50 of OSSL_325096 on ATPase activity was 7-10μM, while IC50 of cell survival in MM cells was 0.1-0.8μM, suggesting that OSSL_325096 may have other anti-myeloma function in addition to VCP inhibition. RNA-sequencing of MM cells treated with OSSL_325096 revealed that several pathways including mTROC1 signaling, TNFα signaling, and unfold protein response, were activated by OSSL_325096. Finally, OSSL_325096 was administered to xenograft mice with MM cell tumors and inhibited the tumor growth *in vivo* (Figure 4).

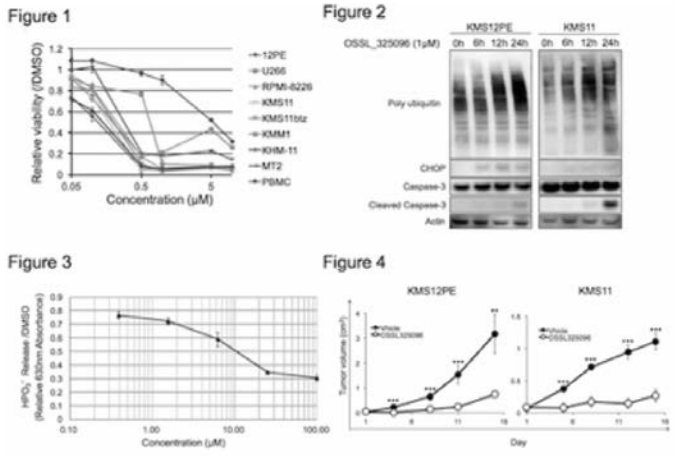

Figure 1.

Summary/Conclusions: The present data suggest that OSSL_325096 may be novel anti-myeloma drug candidate partially through its direct inhibition activity of VCP.

E1206

A NOVEL PREDICTIVE MODEL COMBINING LINCRNAS AND PROTEIN CODING GENES IN MULTIPLE MYELOMA

M. Samur[1,2,*], A. Gulla[1], M. Fulciniti[1], R. Szalat[1], A. Aktas Samur[1], M. Shamas[1], F. Magrangeas[3], S. Minvielle[4], K. Anderson[1], G. Parmigiani[1], H. Avet-Loiseau[5], N. Munshi[1]
[1]Dana Farber Cancer Institute, [2]Harvard Medical School, Boston, United States, [3]Centre de Recherche en Cancérologie Nantes, [4]Institut de Recherche Thérapeutique, Nantes, [5]Cancer Research Center of Toulouse, Toulouse, France

Background: RNA has diverse sets of regulatory functions and a recent analysis of RNA repertoire has identified a large numbers of non-coding transcripts. One of which, long intergenic non-coding RNA (lincRNA) with transcripts longer than 200 nucleotides, are located between the protein coding genes and do not overlap exons of either protein-coding or other non-lincRNA genes. lincRNAs have been considered to provide regulatory functions, however, their precise role in cellular biology remains unclear.
Aims: Here, we have studied lincRNAs using uniformly treated patients to show their impact on survival outcome in MM.
Methods: We performed RNA-seq on CD138+ MM cells from 360 newly-diagnosed patients and 18 normal plasma cells (NPM) and analyzed for lincRNA and protein coding genes. MM patient data for clinical characteristics, cytogenetic and FISH as well as clinical survival outcomes were also analyzed and correlated with lincRNA data.
Results: Using only the expressed lincRNAs, we developed a risk prediction signature. The Kaplan-Meier estimates of EFS at 4 years were 53.3% (95% CI, 45.1% to 63.1%) and 32.6% (95% CI, 25.1% to 42.2%), and OS at 4 years were 93.2% (95% CI, 88.9% to 97.6%) and 71.1% (95% CI, 62.9% to 80.3%) in our patients having a low or high risk score. We then combined lincRNA signature with known expression signatures and improved the risk prediction for known expression signatures dramatically. We validated our results on independent large cohort with newly diagnosed MM RNAseq data. When applied to patient cohort separated by other risk categorization including minimal residual disease status (MRD), cytogenetic risk status (del17p, t(4;14) and t(14;16)) and International Staging System (ISS), lincRNA signature was able to further identify patients with significant differential survival outcomes.
Summary/Conclusions: In summary, we report that lincRNAs have an independent effect on survival outcome in MM and provides rational for its use in risk stratification as well as to understand biological impact. Combined risk prediction with other risk features improve the prediction power and helps to create better classification in MM.

DYNAMIC IMMUNOHISTOCHEMICAL EVALUATION OF MARROW MICROENVIRONMENT MODIFICATIONS IN PATIENTS WITH SMOLDERING MYELOMA

A. Mussetti[1,*], A. Pellegrinelli[2], N. Cieri[3], M. Pennisi[3], G. Garzone[2], F. Dominoni[2], A. Cabras[2], P. Corradini[4], V. Montefusco[1]
[1]Hematology and Adult Bone Marrow Transplantation, [2]Department of Pathology and Laboratory Medicine, Fondazione IRCCS Istituto Nazionale Tumori, [3]Università degli Studi di Milano, Milano, Italy, [4]Department of Oncology and Hemato-oncology, Università degli Studi di Milano, Milano, Italy

Background: In most cases, multiple myeloma (MM) is preceded by an asymptomatic status known as monoclonal gammopathy of unknown significance (MGUS) or smoldering multiple myeloma (SMM). The mechanisms of progression from SMM to MM are not well understood. Despite an increasing evidence of an immune system dysregulation in the setting of MM characterized by a tumor tolerating microenvironment, the immunosurveillance profile in the setting of SMM has never been investigated.
Aims: Our aim was to identify a progressive dysregulation of marrow microenvironment in sequential samples of SMM patients. Secondly, we hypothesized a difference in the microenvironment of the patients with progressed SMM *versus* those with stable SMM.
Methods: We performed extensive immunohistochemical analysis of bone marrow samples of 16 patients affected by SMM at time 0 (16 samples) and at +24 months (+/- 4 months, 16 samples). Half of these patients developed MM at 24 months (progressed SMM), the other half remained asymptomatic (stable SMM). Immunohistochemical panel comprised the following markers: microenvironment cell composition (CD138, CD4, CD8, CD3, CD45, CD56, CD68), loss of immunogenicity (PDL1, PDL2, PD1, LAG3, CTLA-4, IDO), loss of antigenicity (HLA-DR). Immunogenicity and antigenicity markers expression was described as percentage on the total of marrow plasma cells and non-plasma cells separately. A first analysis compared the samples of the whole cohort at time 0 and +24 months (32 samples, paired t-test). A linear correlation was performed to study the expression of T cell inhibitory ligands on plasmacells and their respective receptors on marrow non-plasma cells (HLA-DR with LAG3, PDL1 with PD-1). A second analysis compared, at time 0 and +24 months, the samples of stable SMM *versus* progressed SMM (16 samples each analysis, t-test).
Results: In the first analysis, we found a significant increase between time 0 and +24-month samples of CD4+ (11% *vs* 17%, p<0.01), CD8+ (15% *vs* 18%, p<0.01), CD4/CD8 ratio (0.75 *vs* 0.94, p<0.01), PDL1 on plasmacells (1% *vs* 12%, p=0.03), HLA-DR on plasmacells (7% *vs* 10%, p=0.04), HLA-DR on non-plasmacells (29% *vs* 39%, p=0.01), LAG3 on non-plasmacells (4% *vs* 10%, p=0.04). Interestingly, we found a significant correlation between LAG3 and its ligand HLA-DR (r=0.47, p=<0.01). In the second analysis we compared stable SMM *versus* progressed SMM at time 0 and at +24 months. At time 0, we found only an increased CD68-KP1 expression in favor of stable SMM group (28% *vs* 23%, p=0.01). At time +24 months, no differences were observed but an increased plasma cell marrow infiltration in the progressed SMM group (50% *vs* 26%, p<0.01).
Summary/Conclusions: First, we observed an increase in inflamed microenvironment markers (increase in CD4+ and CD8+ cell count in favor of CD4+ population and HLA-DR expression on plasmacells and non-plasmacells) during the course of SMM. Secondly, expression of T cell inhibition markers (PDL1, LAG3) was significantly augmented during disease progression. For the first time, we reported a comprehensive analysis of microenvironment modifications in the setting of SMM with a paired-samples analysis. Features of an immune dysregulated microenvironment were observed. In particular, increased in PDL1 and LAG3 expression could be of clinical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.

E1208

IMMUNE CELL PROFILING IN BONE MARROW OF MYELOMA PATIENTS POST AUTOLOGUS STEM CELL TRANSPLANT SHOWS PRESENCE OF CYTOTOXIC CD4 AND CD8 CELLS, WITH PROMINENT LAG-3 EXPRESSION AND OTHER CHECKPOINT MARKERS

N. Alrasheed[1,*], A. Furness[1], D. De-Silva[1], D. Galas-Filipowicz[1], M. Chin[1], L. Lee[1], J. Henry[1], M. Pule[1], S.A. Quezada[1], K. Yong[1]
[1]UCL Cancer institute, university college london, London, United Kingdom

Background: Multiple myeloma (MM) is a plasma cell malignancy that remains incurable, despite therapeutic advances. Immunotherapies have recently shown much promise in this and other cancers, and are under intense investigation. Autologous stem cell transplantation (ASCT) is standard of care in young fit newly diagnosed patients. In the post-ASCT setting, the minimal disease burden and re-constituting immune system may be a favourable context for immunotherapies, including cellular therapy and checkpoint blockade.
Aims: We aimed to characterise the immune landscape in the bone marrow (BM) of MM patients post- ASCT, to identify candidate immune checkpoint proteins for therapeutic targeting.
Methods: BM aspirates were obtained from patients with MM at 3months post ASCT (n=28), and 6-12months post ASCT (n=41) at University College Hospital. Control BM aspirates were collected from healthy volunteers undergoing BM harvesting with the Anthony Nolan. Immunofluorescence surface staining was performed using antibodies to CD3, CD4, CD8, LAG-3, PD-1, HLA-DR, ICOS and the intracellular markers GzmB and Foxp-3. All p-values indicate differences from normal donors unless otherwise stated.
Results: In the post-ASCT BM, absolute numbers of CD8 cells exceeded CD4 cells as early as 3months post-ASCT, suggesting the BM compartment is rapidly filled with CD8 cells. Although absolute numbers of CD4 effectors (CD4+Foxp3-) were either similar (3 months) to or lower (6-12months, p<0.05) than healthy donors, there was a higher proportion of cytotoxic (GzmB+) CD4 cells (3months median 30.4%, range 0.2-89.7%, p<0.01 *vs* control median 2.6%, range 0.2-33.4% and 6-12months, median17.6%, range 0.4-100%, p<0.05). CD4 effectors also expressed activation markers: Inducible co-stimulator (ICOS, 3months median 20.2%, range 2.9-80.6% p<0.05 *vs* control median 8.6%, range 2-22% and 6-12months median 33%, range 1.8-80.7%, p<0.01) and HLA-DR (p<0.05), and high levels of lymphocyte-activated gene-3 (LAG-3, 6-12months median 29.6%, range 12.2-62.1%, p<0.05 *vs* control median 17.9%, range 8.2-32.4%) Significant numbers of CD4 effectors co-expressed LAG-3 and GzmB (p<0.05), as well as LAG-3 and ICOS (p<0.05). Absolute numbers of CD8 effectors (CD8+Foxp3-) in post ASCT patients were not different from healthy donors. Similar to CD4 effectors, a significantly higher proportion of CD8 effectors displayed cytotoxic phenotype (GzmB+, 3months median 88%, range 15.2-98.3%, p <0.0001 *vs* control median 30.3%, range 5.8-71.4% and 6-12months median 81.5%, range 19.4-100%, p <0.0001) as well as increased levels of HLA-DR (p<0.05) post ASCT. CD8 effectors also displayed high co-expression of LAG-3 and GzmB (p<0.05), but overall levels of LAG-3 were not significantly higher than controls. Both CD4 and CD8 effectors expressed PD-1, however, levels were not significantly higher compared to healthy donors. Patients whose BM contained higher levels of activated (and cytotoxic) CD4 effectors also had similar phenotype of CD8 effectors. We correlated immune checkpoint protein expression with disease response in patients at 12months post ASCT. Patients with residual disease (PR) had higher levels of cytotoxic (Foxp-3-GzmB+) CD4 and CD8 effectors (p<0.05) with co-expression of LAG-3 on cytotoxic CD4 effectors, but no differences in PD-1 expression were seen.
Summary/Conclusions: The BM of MM patients following ASCT contains activated CD4 and CD8 effectors, but high co-expression of LAG-3 suggests that these cells may be functionally suppressed. Patients with larger amounts of residual disease have higher numbers of cytotoxic CD4 and CD8 cells, and the co-expression of the checkpoint protein LAG-3 may provide a rationale for blockade of this pathway.

E1209

INHIBITION OF EXTRACELLULAR VESICLE SECRETION INDUCES APOPTOSIS OF BONE MARROW STROMAL CELLS: TOWARDS SOIL-TARGETED THERAPY IN MULTIPLE MYELOMA

T. Umezu[1,*], S. Imanishi[2], S. Yoshizawa[1], K. Ohyashiki[1], J. Ohyashiki[2]

[1]Department of Hematology, [2]Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, Japan

Background: Bone marrow stromal cells (BMSCs) interact with multiple myeloma (MM) cells in the bone marrow, and also create a permissive microenvironment for MM cell growth and survival. Recent evidence indicated that MM cell-BMSC communication via extracellular vesicles (EVs) plays an important role in the MM microenvironment.
Aims: In this study, we investigated the biological property of EVs and miRNAs in EVs derived from BMSCs, aiming to establish the emerging strategies to target MM microenvironment to prevent tumor growth and spread.
Methods: Bone marrow samples were obtained from MM patients (age 56 to 82, n=20) and monoclonal gammopathy of undetermined significance (MGUS) patients (age 44 to 82, n=13) in accordance with the Declaration of Helsinki and using protocols approved by the research Ethics Committee of Tokyo Medical University (IRB No. 2648), and BMSCs derived form MM patients (MM-BMSCs) andmgUS patients (MGUS-BMSCs) were isolated by the classical adhesion method. EVs were isolated from conditioned medium of BMSCs using a Exoquick-TC (SBI). The size of EVs was confirmed using a NanoSight LM10 (Malvren). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI). For functional analysis of candidate miRNAs, the miRNA mimics (Ambion) were transfected into BMSCs using HiPerFect (Qiagen). Cell viability of miRNA-overexpressed BMSCs were determined using WST-8 (Dojindo), and Apoptosis rates were determined using Caspase-Glo assays (Promega). To assess the effect of the inhibit on EV secretion, BMSCs were treated with 10 μM GW4869 (nSMase2 inhibitor, Sigma) for 48h.
Results: MM-BMSCs andmgUS-BMSCs had a fibroblast-like morphology in culture, and were homogeneously $CD73^+$, $CD90^+$, $CD105^+$, $CD34^-$, and $CD45^-$. MM-BMSCs had a higher expression of α-smooth muscle actin (α-SMA) thanmgUS–BMSCs. The nanoparticle size distribution of EVs derived from BMSCs was approximately 50 nm. We found high expression of miR-10a in the EVs derived MM-BMSCs, while the expression of intracellular miR-10a was low in MM-BMSCs. We therefore hypothesized that low expression of cellular miR-10a might be important for survival of MM-BMSCs; As a result, miR-10a was packaged into EVs, and they were released to the extracellular space. To test the hypothesis, miR-10a mimic was transfected into MM-BMSCs andmgUS-BMSCs. Of note is that overexpression of miR-10a inhibited cell proliferation and induced apoptosis of MM-BMSCs, while the cell proliferation and apoptosis ofmgUS-BMSCs were not affected by the overexpression of miR-10a. We also found that inhibition of EV release with GW4869 promote the accumulation of intracellular miR-10a in MM-BMSCs, and EV-release inhibitor also can inhibited cell proliferation and induced apoptosis of MM-BMSCs.
Summary/Conclusions: Our results provide the possibility that the inhibition of EV secretion induced apoptosis of MM-BMSCs that can support MM cell growth and survival in BM microenvironment.

E1210

SINGLE-NUCLEOTIDE POLYMORPHISM IN THE PBK GENE IS CLOSELY ASSOCIATED WITH MYELOMA CELL PROLIFERATION

I. Hanamura[1,*], A. Ota[2], S. Karnan[2], M. Wahiduzzaman[2], S. Mizuno[1], K. Uchino[1], J. Kanasugi[1], T. Horio[1], S. Murakami[1], S. Suzuki[3], R. Ueda[3], S. Tsuzuki[2], H. Konishi[2], Y. Hosokawa[2], A. Takami[1]
[1]Division of Hematology, Department of Internal Medicine, [2]Department of Biochemistry, [3]Department of Tumor Immunology, Aichi Medical University, Nagakute, Japan

Background: Elevated expression of *PDZ binding kinase (PBK)*, which encodes a serine/threonine kinase, has been reported to be associated with a poor prognosis in a variety of cancers. The public gene expression profiling data also showed that higher expression of *PBK* was related with a poor prognosis in myeloma. However, the molecular mechanisms of *PBK* expression have never been investigated in myeloma.
Aims: The aim of this work was to elucidate *PBK* gene functions associated with myeloma cell growth *in vitro* and *in vivo*.
Methods: Eight human myeloma cell lines including ANBL-6, 8226, OPM2, and KMS-11 were used in this study. The expression levels of mRNA and protein of *PBK* were detected by real-time RT-PCR and western blotting, respectively. The genome sequence of the whole *PBK* gene was determined using the dye terminator method. Knockout of *PBK* was performed using CRISPR-Cas 9 system. A single guide RNA sequence for *PBK* was in exon 3 and *PBK* expression was completely disrupted (Fig. 1). Transfection of the plasmid expressing *PBK* to cells was performed using with the Amaxa Nucleofector system. Cell viability and proliferation were examined by the MTT and colony formation assay. The KMS-11 cells were subcutaneously injected to mice and tumor volumes were observed every 3 to 4 days.
Results: High expression of mRNA and protein of PBK was observed in 8/8 myeloma cell lines. Genome sequencing revealed the rs3779620 polymorphism in the *PBK* exon 5, in which the A to G transition results in the N107S substitution. A/A, A/G and G/G were found in 88, 0 and 12%, respectively. Of note, *PBK* inhibition by CRISPR-mediated knockout enhanced cell proliferation in ANBL-6, 8226, and OPM2 cells, all of which carry $PBK^{A/A}$. Surprisingly, in the KMS-11 cells carrying $PBK^{G/G}$, *PBK* inhibition by CRISPR-mediated knockout suppressed cell growth *in vitro* and in xenograft mice (Fig. 2). Moreover, exogenous expression of $PBK^{G/G}$ augmented cell proliferation in the PBK-deficient OPM2 cells, which carry $PBK^{A/A}$ originally. Furthermore, Thr 9 phosphorylation on PBK was increased in cells expressing $PBK^{G/G}$ compared with those cells expressing $PBK^{A/A}$.

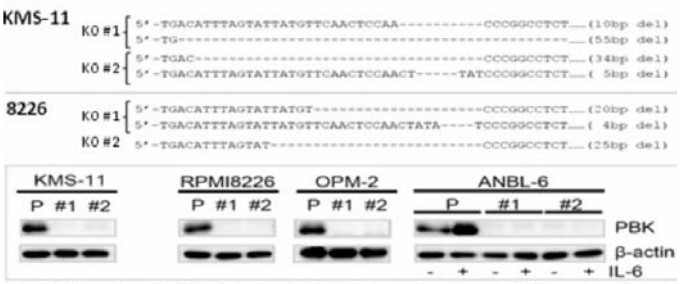

Fig. 1. Knockout of *PBK* using CRISPR-Cas 9 system. *PBK* expression was completely disrupted. 8226, ANBL-6, and OPM2 carry $PBK^{A/A}$ and KMS-11 $PBK^{G/G}$. P; positive control. #1 and #2; clone numbers.

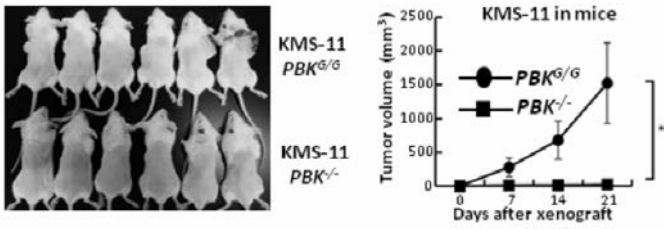

Fig. 2. $PBK^{G/G}$ inhibition by CRISPR-mediated knockout suppressed cell growth in xenograft mice. $PBK^{-/-}$; PBK-deficient cells.

Figure 1.

Summary/Conclusions: Our findings indicate that expression of $PBK^{G/G}$ was associated with myeloma cell proliferation, while $PBK^{A/A}$ was likely linked to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with $PBK^{G/G}$. These results provide a novel insight into the mechanisms underlying myeloma cell growth and *PBK* rs3779620 genotype is a potential stratification and therapeutic target for plasma cell dyscrasias.

E1211

THE HISTONE METHYLTRANSFERASES G9A/GLP REPRESENT NEW PROMISING TARGETS FOR THE TREATMENT OF MULTIPLE MYELOMA

E. De Smedt[1,*], J. Devin[2], H. Liu[3], A. Maes[1], K. Maes[1], K. De Veirman[1], E. Menu[1], K. Vanderkerken[1], J. Moreaux[2], E. De Bruyne[1]
[1]Department of Hematology and Immunology-Myeloma Center Brussels, Vrije Universiteit Brussel, Brussels, Belgium, [2]Laboratory for Monitoring Innovative Therapies, Institute of Human Genetics, CNRS, Montpellier, France, [3]Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Multiple myeloma (MM) is a clonal plasma cell malignancy which mainly resides in the bone marrow. In cancer cells, the epigenetic landscape is known to be highly disturbed. In line, numerous epigenetic aberrations have been described in MM, resulting in deregulated gene expression, disease progression and drug resistance. Targeting deregulated epigenetic modifiers therefore represents an interesting therapeutic approach. G9a (EHMT2) and GLP (EHMT1) are 2 histone methyltransferases which catalyze mono- and dimethylation of histone 3 lysine 9 (H3K9). Importantly, G9a is overexpressed in several cancers, correlating with a poor prognosis.
Aims: Currently, data about the expression and role of G9a/GLP in MM is lacking. The aim of this study is therefore to investigate the functional role of G9a/GLP in MM pathogenesis.
Methods: The prognostic value of G9a/GLP in terms of overall survival was determined in the UAMS-TT2 cohort of newly diagnosed MM patients (n=345, GSE4581) using Maxstat analysis. In addition, we used a panel of 10 human cell lines, 3 murine cell lines and 5 primary patient samples to evaluate the effect of the small molecule inhibitors UNC0638 and BIX01294 on MM cell viability, cell cycle progression and apoptosis. We also assessed the *in vitro* anti-MM activity of BIX01294 in combination with bortezomib or ABT-199. The *in vivo* anti-MM activity of therapeutic BIX01294 treatment was tested using the murine 5TGM1 model. Difference in overall survival between groups was assayed with a log-rank test and survival curves plotted using the Kaplan-Meier method.

Results: Here we report that high expression levels of both G9a and GLP are associated with a worse disease outcome in newly diagnosed MM patients. Moreover, gene set enrichment analysis of patients with high G9a/GLP expression levels displayed a significant enrichment of genes involved in pathways associated with MM disease progression, including the RAS pathway, NF-κB canonical pathway, IRF4 multiple myeloma program and mRNA splicing. Next, we demonstrated that the specific G9a/GLP inhibitors BIX01294 and UNC0638 significantly and potently reduced MM cell viability *in vitro*. Moreover, both inhibitors also induce cell cycle arrest and apoptosis. When comparing between both inhibitors, BIX01294 was found to be the most potent in induce apoptosis. Mechanistic studies for BIX01294 furthermore indicated that BIX01294 treatment resulted in autophagic programmed cell death as evidenced by a strong increase in the formation of LC3B puncta and an increase in LC3II and beclin-1 protein levels. In addition, we found that BIX01294 sensitizes MM cells to the proteasome inhibitor bortezomib and the Bcl-2 inhibitor ABT199. Lastly, therapeutic treatment of 5TGM1 inoculated mice with BIX01294 resulted in a clear delay in tumor progression, as evidenced by a clear decrease in tumor burden and a significant increase in the overall survival of BIX01294 treated mice compared to vehicle treated mice.
Summary/Conclusions: Altogether, our results demonstrate for the first time the importance of the histone methyltransferases G9a/GLP in MM pathogenesis. Furthermore, we show that specific targeting of G9a/GLP induces MM cell apoptosis, enhances MM sensitivity to ABT- 199 and bortezomib and significantly delays tumor progression in the murine 5TGM1 model. Thus, G9a/GLP targeting represents a promising strategy to improve treatment of MM.

E1212

CYTOTOXIC LYMPHOCYTES IN NEWLY DIAGNOSED MYELOMA HAVE REVERSIBLE FUNCTIONAL AND PHENOTYPIC ABNORMALITIES THAT MAY OFFER THERAPUTIC OPPORTUNITIES

F. Seymour[1,*], J. Cavenagh[1], J. Gribben[1]
[1]Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Background: A bi-directional interaction exists between malignant cells and those of the immune microenvironement. This dynamic relationship results in gradual loss of clonal control associated with loss of cytotoxic lymphocyte (CTL) response. Mechanisms of immune escape are varied and include the induction of immune checkpoint pathways, notably the PD1-PDL1 axis. Multiple myeloma is a disease characterised by a pre malignant phase which can evolve into periods of asymptomatic and symptomatic disease. One possible mechanism for disease progression is progressive loss of immunological control. The malignant plasma cell has multiple potentially immune modifying effects including the expression of PDL1 and induction of a pro-tumour micro-environment. The role of CTLs is less well understood.
Aims: To undertake deep immune profiling of the CTL landscape in myeloma in order to establish whether features of immune dysregulation are present and to identify potential therapeutic opportunities.
Methods: Cryopreserved bone marrow from 18 patients with newly diagnosed and untreated myeloma and 9 controls were assessed using a 36 parameter mass cytometry panel. The panel was designed to assess 9 immune checkpoint regulators, 5 cytokines, and markers of proliferation and degranulation across multiple lymphocyte subsets. Samples were stimulated with CD3 and CD28 to assess functional capacity. Dimensionality reducing clustering algorithmic analysis was used alongside traditional data analysis techniques to identify functional subpopulations characterised by expression of multiple markers.
Results: The cytokine profile in newly diagnosed myeloma is shifted towards a pro-tumour microenvironment with particularly marked elevation of TGFb throughout resting CTLs (36.4% v. 66.2%, p=<0.0001). IFNg production is reduced in the resting myeloma effector population (0.33% v. 0.18%, p=0.0099). Stimulation restores the cytokine profile to match that of controls. Myeloma CTLs retain the capacity to proliferate and produce the constituents for cytotoxic granule formation, however elevated PD1 expression alongside other markers of exhaustion suggests a transition towards an exhausted phenotype is occurring. Strongly PD1 expressing populations in myeloma are larger (26% v.43%, p=0.05) and have increased rates of co-expression of CTLA4 (32%v. 64%, p=0.0015), PDL1 (26% v. 47%, p=0.0198) and TIM3 (34% v. 56%, p=0.0241). Populations of CTLS from myeloma up-regulate expression of the TCR co-stimulatory receptors DNAM1 (74% total CD8), NKG2D (45% total CD8) and OX40 (33% total CD8) following stimulation.
Summary/Conclusions: Clear differences can be identified in the functional and phenotypic features of CTLS in myeloma compared to those of controls.The partial nature of these defects and the fact that reversibility can be demonstrated suggests that these cells have not yet reached the stage of irreversible exhaustion. Taken together this data suggests that targeting immune checkpoint regulators at an early disease stage, in order to optimise immunological function and reverse partial defects, is a viable therapeutic strategy to explore. PD1, PDL1, CTLA4 and TIM are all potential immune checkpoint targets. In addition the expression of NKG2D, DNAM1 and OX40 raises the possibility of activating TCR co-stimulation in order to up-regulate antigen specific CTL activity. Combining immunological blockade with other immune optimising agents may enhance the benefit, leading to greater malignant cell clearance.

P53-RESTORING SMALL MOLECULE CP-31398 INDUCES APOPTOSIS VIA INDUCTION OF REACTIVE OXIDATIVE SPECIES IN HUMAN MULTIPLE MYELOMA

Y. Arihara[1,*], K. Takada[1], Y. Kawano[1], N. Hayasaka[1], H. Nakamura[1], S. Kikuchi[1], Y. Kamihara[1], K. Murase[1], H. Ikeda[2], S. Iyama[2], T. Sato[2], K. Miyanishi[1], M. Kobune[2], J. Kato[1]
[1]Department of Medical Oncology, [2]Department of Hematology, Sapporo Medical University, Sapporo, Japan

Background: Reactive oxygen species (ROS) are normal byproducts of a wide variety of cellular processes. ROS have dual functional roles in cancer cell pathophysiology. At low to moderate levels, ROS act as signaling transducers to activate cell proliferation, migration, invasion, and angiogenesis. In contrast, high levels of ROS induce cell death. In multiple myeloma (MM), ROS overproduction is the trigger for apoptosis induced by several anticancer compounds, including proteasome inhibitors. However, no drugs that mainly affect oxidative stress are currently used for treatment of MM in the clinic. In MM, p53 status is an independent prognostic marker, since patients harboring p53 abnormalities are highly resistant to standard therapies, and the incidence of p53 mutations and deletions increases during disease progression. Therefore, restoration of p53 is an attractive strategy for treating advanced relapsed and refractory MM (RRMM) patients. CP-31398 (CP) is a small molecule that activates wild-type p53 or restores tumor-associated p53 mutants to wild type p53 function in multiple human cancer cell lines; this leads to cell cycle arrest and/or apoptosis. The growth of rhabdomyosarcoma cell lines can be inhibited by p53-dependent induction of ROS, but it is not clear whether CP-induced cytotoxicity proceeds via a similar pathway.
Aims: Our study was aimed at evaluating the anti-myeloma activity of CP.
Methods: MM cell lines (MM1S, RPMI8226, U266, KMS5, OPM2, Delta47, KMS11) and three primary MM samples were treated for 48 h with CP. Subsequently, the inhibitory effect of CP on MM cell line growth was assessed using a WST-1 assay. In order to elucidate the cytotoxic mechanism of CP, immunoblotting and flow cytometry analysis were performed. Measurements of cytosolic and mitochondrial ROS were performed with CellROX Deep Red or MitoSOX Red. For quantification of ROS, cells were analyzed by flow cytometry and fluorescence microscopy. The therapeutic potential of CP was evaluated by its ability to suppress tumor growth *in vivo* using the subcutaneous RPMI8226 murine xenograft model for human MM.
Results: In this study, we have demonstrated that the p53-activating small molecule CP-31398 effectively inhibited the growth of MM cell lines and primary MM isolates from patients with IC_{50} values in the range of 2.51–11.2 μM. CP also suppressed the growth of MM xenografts in mice. Mechanistically, CP was found to induce intrinsic apoptosis in MM cells via increasing mitochondrial and cytosolic ROS production. Interesting, CP-induced apoptosis occurs regardless of the cells' p53 status, suggesting that CP has additional mechanisms of action. In addition, we found that CP acted synergetic with the protease inhibitor carfilzomib (CFZ) in MM cells, providing a framework for further studies of CP alone and in combination with CFZ to improve the prognosis for MM patients.
Summary/Conclusions: Our findings indicate that CP could be an attractive candidate for treatment of MM even in patients with p53 abnormalities; this would satisfy an unmet clinical need, as such patients currently have a poor prognosis.

E1214

TUMOR MICROENVIRONMET TRANSFORMATION FROMmgUS TO MYELOMA IS ASSOCIATED WITH PRO-TUMORAL ACTIVATION OF MESENCHYMAL STROMAL CELLS (MSC)

C. Giallongo[1,*], D. Tibullo[1], N. L. Parrinello[1], P. La Cava[1], G. Camiolo[1], M. Tummino[1], N. Caporarello[1], C. Anfuso[1], C. Conticello[1], A. Romano[1], F. Di Raimondo[1]
[1]Clinical and Molecular Biomedicine, section of Hematology, University of Catania, catania, Italy

Background: A well-recognized feature of MM is the intimate relationship between plasma cells (PC) and bone marrow microenvironment, characterized by a modified extracellular matrix, enhanced angiogenesis and presence of cells with immune suppressive activity, including tumor-associated macrophages and myeloid-derived suppressor cells (MDSC). Recently, we demonstrated that MM-MSC are able to convert normal immature myeloid cells in MDSC contributing to immune-escape mechanisms.
Aims: We hypothesize that MSC derived from Smoldering myeloma (SMM) and MM are in an activated status that promotes tumor growth and and tumor microenvironment trasformation.
Methods: Human peripheral blood mononucleated cells (PBMC) isolated from healthy subjects (HC) were cultured with healthy controls (HC-),mgUS-, SMM- or MM-MSC. After 6 days,. neutrophils (N) were isolated using anti-CD66b magnetic microbeads and were tested *in vitro* for their ability to induce angiogenesis and suppress T cell proliferation.

Results: Only N educated by SMM- and MM-MSC (both from patients at diagnosis, relapsed and refractory) significantly up-regulated Arg1, NOS2 and TNFα and exhibited suppressive effect with a reduction of T cell proliferation ($p<0.001$). By co-culturing educated-N with Human Brain Microvascular Endothelial Cells (HBMEC), we observed increased both tube length and number of branch points only in conditions where HBMEC were incubated with MM-MSC or MMref-MSC educated-N ($p<0.05$). Adding Bortezomib, Lenalidomide or Pomalidomide during co-culture of PBMC with MM-MSC, isolated N showed a significant reduction of pro-angiogenic activity but did not lose immunosuppressive ability. To examine if PC play a role in MSC "activation", before performing co-cultures with PBMC, we pre-treated HS-5 or HC-MSC with MM cell lines. PC pre-treatment drives healthy MSC to activate N in immunosuppressive and pro-angiogenic cells. Implanting of mixtures of fluorescently labeled MM cells and healthy- or MM-MSC into zebrafish, animals coinjected with PC and MM-MSC showed enhanced tumor colonization and growth compared with those injected with PC and healthy MSC.
Summary/Conclusions: Tumor microenvironmet transformation frommgUS to MM is associated with progressive activation of MSC that have a pro-tumoral activity. Indeed SMM- and MM-MSC polarize N in immunosuppressive and pro-angiogenic N (N2) in vitro. In addition, MM-MSC facilitate MM growth *in vivo* confirming their central role in tumor progression.

Background: CR is a prerequisite for long term responses, progression free survivals, and ultimately overall survivals and cure. In the era of novel agents, many MM patients can achieve stringent CR (sCR), *i.e.* disease disappearance at serological, immunoistochemical level plus negativity of free light chains (FLC). On the other hand most of these patients still will relapse and minimal residual disease (MRD) detection will play a crucial role in the very next future. Recently, two 8 colours tubes panel developed by the EuroFlow Consortium can detect MRD with an increased sensitivity and can be applied as standardized method to study multiple myeloma (MM) patients.
Aims: While many studies have looked at MRD status sequentially and soon after autologous or allogeneic stem cell transplantation with flow or molecular techniques, little is known about long term remission patients (>5-10 years) and in particular if more sensitive techniques such as NGF or NGS can still detect minimal disease in those patients. Aim of the study was to analyse patients with MM in >VGPR with next generation flow at>2 and>5 years of lasting remission.
Methods: Clinical assessment definition of CR status included serum and urine immunofixation, free light chain determination, imaging study with CT-PET, bone marrow aspirate, bone core biopsy. 56 MM patients (M/F= 30/26), were studied with NGF at two GTMM centers between February 2016 and February 2017. 28/56 (50%) patients were in sCR at the moment of the study at a median of 40 months after therapy (range 3-140). 28/56 (50%) patients were in VGPR at study analysis according to new IMWG response criteria. N= 12, 25 and 44 patients had a remission disease >5 years, >2 years, and <5 years, respectively. Two tube assay incorporated 8 antibodies each: CD38, CD56 β2-Microglobulin, CD19, κ Anti-Kappa Anti-Lambda CD45 CD138, and CD38, CD28, CD27, CD19, CD117, CD81, CD45 and CD138 (OneFlow™ *PCST* and PCD, BD Biosciences) and were utilized to detect MRD level with a lyse-wash-and-stain sample preparation protocol by flow cytometry (FACScanto II, BD, Biosciences). Accurate identification of BM plasma cells (PCs) and discrimination between phenotypically aberrant (aPC) and normal PC (nPC) were carried out after acquisition and analysis of >2 x 10^6 cells (Diva 8, BD Biosciences).
Results: MRD+ status was detected in 23/56 (41%) of the patients. 4/12 (2 33%) were MRD positive at >5 years remission (2 sCR, 2 VGPR) (median 96 months range 72 – 186 months); 20/44 (45%) were positive at<5 years of remission (3 CR; 17 VGPR)(median 9,5 range 3 – 46 months). 9/25 (36%) were MRD + after >2 years of remission (2 sCR, 7 VGPR) (median 46 months range 24 – 186 months). As expected being in sCR was correlated with a low MRD+ status 5/28 (18%) (2 patients after >5 years, 3 patients after <5 years). Interestingly looking at long lasting remission, *i.e.* >5 years, the 4/14 patients that resulted MRD+ displayed anmgUS like –plasmacell immunophenotype (prevalence of normal plasmacells *vs* aberrant monoclonal) with a PCn/PCtot ratio of 48%, 95%, 35%, 30%. CT/PET was positive in 22/56 patients. All patients in sCR were CT/PET negative.
Summary/Conclusions: In conclusion NGF showed that MM patients with long remission status can be considered disease free/cured with a high sensitivity method. MM patients that display anmgUS–like phenotype after achieving a CR can have long lasting remissions meaning disease control. Patients in sustained CR after 2 years can have high percentage of MRD negativity. Larger studies are warranted to identify patients who need treatment consolidation or continuous treatment based on MRD+ status *vs* others who could stay treatment free with social and economical benefits.

THE NOTCH PATHWAY IN THE INTERPLAY BETWEEN MYELOMA CELLS AND ENDOTHELIUM IN THE BONE MARROW NICHE

M.T. Palano[1,*], N. Palatonova[2], I. Saltarella[3], S. Garavelli[1], M. Colombo[1], F. Baccianti[1], A. Neri[2], R. Ria[3], R. Chiaramonte[1]
[1]Scienze della Salute, [2]Oncologia ed emato-oncologia, Università degli Studi di Milano, Milano, [3]Medicina interna e Oncologia clinica, Università di Bari, Bari, Italy

Background: Angiogenesis is a hallmark of tumors, and it is a peculiar characteristic in bone marrow (BM) of multiple myeloma (MM) patients. MM is a still incurable disease that strongly depends on interactions with BM microenvironment. Endothelium of MM patients displays malignant behavior as compared to a healthy counterpart (1). MM displays a dysregulation of the Notch pathway due to Jagged ligands and Notch receptors overexpression. This condition brings to the generation of homotypic and heterotypic interaction loops that sustain MM cells. Moreover, Notch pathway represents a bridge in the dialogue with BM resident cells, including osteoclast and BM stromal cells (BMSCs), although its role in the crosstalk of MM and endothelium is still to be clarified.
Aims: The aim of this study is to investigate Notch role in MM crosstalk with endothelium exploiting 2D assays and 3D organoid systems to mimic tumor microenvironment (TME).
Methods: The Notch ligands, Jagged1 and 2, were silenced in the MM cell line RPMI8226 (RPMI8226$^{shJAG1/2}$) using an inducible lentiviral vector carrying two short hairpin RNAs targeting Jagged1 and 2. To mimic the endothelial compartment the human pulmonary arterial endothelial cells (HPAECs) were used and for the stromal compartment, the GFP$^+$HS5 cell line. Matrigel and wound healing assays were set up to investigate Notch role in modulating respectively the angiogenic potential of MM cells co-cultured with HPAECs and HPAEC motility in response to MM-derived soluble factors. To develop a TME-like system, a decellularized extracellular matrix (dECM) was used as a physiologic scaffold for organoid generation. dECM was produced by treating murine fibroblast NIH3T3 with ascorbic acid and was loaded with cells for organoids generation. We evaluated apoptosis of MM cells in single culture and co-culture with BMSCs or HPAECs by flow cytometry.
Results: Matrigel assay of HPAEC co-cultured with MM cells showed that direct contact increased angiogenic potential of HPAEC to form a grid of tubes; this effect is significantly reduced when HPAECs are co-cultured with RPMI8226$^{shJAG1/2}$ cells, indicating a key role of Notch signaling in endothelial stimulation. Wound healing assay demonstrated that Notch signaling affects HPAEC motility, since it is reduced when Jagged ligands are silenced. Concerning the 3D-organoid generation, our results indicate that the handcrafted dECM was a suitable scaffold. Moreover, apoptosis assays indicated that MM cells displayed an increased survival when cultured in the presence of BMSCs, that consistently with their recognized protective role; no significant difference in MM cell apoptosis was observed in the presence of endothelial cells. On the contrary, we have observed that endothelial cells were protected by MM cells suggesting that MM cells improve angiogenesis by preventing endothelial cells apoptosis.
Summary/Conclusions: These results indicate a novel role for Notch pathway in MM-EC crosstalk suggesting that the Notch pathway activation in MM cells can increase their proangiogenic potential. 3D-organoid mimics BM microenvironment and may be used as a novel tool to recapitulate the interactions of BM and tumor cells beyond the animal models.

MIR-101-3P REGULATES BONE MARROW STROMA-INDUCED DRUG RESISTANCE IN MULTIPLE MYELOMA CELLS BY TARGETING SURVIVIN AND MODULATING CELL-CELL ADHESION

J. Abdi[1,*], Y. Chen[1], N. Rastgoo[1], H. Chang[2]
[1]University Health Network, Toronto, Canada, [2]Lab Hematology, University Health Network, Toronto, Canada

Background: In multiple myeloma (MM), bone marrow stromal cells (BMSCs) protect MM cells against cell death by direct or indirect interaction. This phenomenon can partly explain *de novo* or acquired drug resistance in MM. Findings of relevant studies indicate activation of some oncogenic or survival pathways including PI3K/mTOR, Ras/MAPK, NFkB and Wnt. However; the potential regulatory mechanisms and druggable targets have not been clearly elucidated.

Aims: To understrand the role of stomal induced drug resistance and to identify new therapeutic target in myeloma
Methods: GFP-tagged human myeloma cell lines, 8226, U266 and MM.1s, were co-cultured with MM patient-derived BMSCs or HS.5 cells with or without BTZ for 24 h. MM cells in monocultures were used as controls. Co-cultures were then applied to magnetic cell separation to isolate MM cells for downstream analyses including western blotting and mRNA or miRNA qPCR arrays. Furthermore, percent apoptosis of gated GFP^+ cells was determined using FACS. In other experiments, MM cells were exposed to BMSCs pre-treated with Brefeldin-A (BFA) or separated with a transwell (TW) insert. For functional analysis, miR-101-3p was overexpressed using lentiviral transduction and survivin gene was silenced using siRNA. MM cells were then seeded on BMSCs in presence or absence of BTZ. GFP fluorescence-based adhesion, cytotoxicity and annexin-V/PI apoptosis were applied.
Results: qPCR arrays showed that BMSCs up- or down-regulated several mRNAs and miRNAs in MM cells. Survivin (BIRC5) was confirmed to be consistently upregulated in 3 MM cell lines at both mRNA and protein levels. In contrast, miR-101-3p was confirmed to be significantly downregulated by stroma in MM cells. Moreover, suppression of miR-101-3p or upregulation of survivin was reversed partially when BMSCs were pre-treated with BFA but highly significantly when they were separated from MM cells with a TW insert. The same rescue pattern was observed in apoptosis FACS analysis indicating that direct cell-cell adhesion was more effective in BMSC-induced modulations in MM cells. Next we identified that survivin was a direct target of miR-101-3p, overexpression of miR-101-3p suppressed survivin mRNA/protein. As indicator of involvement in stroma-mediated drug resistance, survivin and miRNA-101-3p were not affected by BTZ in MM cell-BMSCs co-cultures compared to monocultures. Furthermore, miR-101-3p overexpression or silencing of survivin increased BTZ-induced apoptosis in MM cells in the absence or presence of BMSCs significantly overcoming stroma-mediated drug resistance. To test whether miRNA-101-3p could also regulate adhesion of MM cells to BMSC, we found that miRNA-101-3p significantly reduced adhesion of MM cells to HS.5 and primary MM BMSCs compared to scrambled control. This finding suggests that miRNA-101-3p regulates cell adhesion-mediated drug resistance (CAMDR) by modulation of MM-BMSC adhesion.
Summary/Conclusions: Our results identify a mechanism whereby BMSCs induce drug resistance in MM cells by upregulating survivin and downregulating miRNA-101-3p which directly targets survivin. Overexpression of miRNA-101-3p or silencing of survivin sensitizes MM cells to BTZ significantly overcoming stroma-induced drug resistance. These findings disclose a role of survivin-miRNA-101-3p axis in regulation of BMSCs-induced BTZ resistance in MM cells, thus provide a rationale to further investigate the anti-myeloma activity of miR-101-3p in combination with BTZ as a potential therapeutic strategy in MM.

ARQ-197, A SMALL-MOLECULE INHIBITOR OF C-MET, REDUCES TUMOUR BURDEN AND PREVENTS TUMOUR-ASSOCIATED BONE DISEASE IN A MURINE MODEL OF MYELOMA

A. Chantry[1,*], E. Holly[1], M. Fisher[1], D. Jenny[1], L. Michelle[1], L. Darren[1]
[1]Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom

Background: The receptor tyrosine kinase c-Met, its ligand HGF, and their signalling pathway, have all been implicated in the pathogenesis of myeloma. In myeloma patients with elevated levels of HGF their prognosis is known to be poor. Therefore, targeting these molecules or their pathway in such patients may be of great benefit. We hypothesised that ARQ-197 (Tivantinib), a small molecule c-Met inhibitor, would reduce myeloma cell growth and prevent myeloma-associated bone disease in a murine model.
Aims: 1. Assess effects of ARQ-197 on myeloma cell proliferation. 2. Assess effects of ARQ-197 treatment on tumour burden in murine models of myeloma and 3. Assess effects of ARQ-197 treatment on myeloma bone disease in murine models of myeloma.
Methods: *In vitro* we assessed the effects of ARQ-197 (0.1563 μM - 5 μM) on myeloma cell proliferation, cytotoxicity and c-Met protein expression in the JJN3 human cell line. *In vivo* we intravenously injected NOD/SCID-γ mice with 10^6 JJN3 cells and 1 week later treated mice with either ARQ-197 (200mg/kg/day, 5 times per week by oral gavage) or vehicle for 2 weeks.
Results: *In vitro* exposure of JJN3 cells to ARQ-197 (0.625 μM - 5 μM) resulted in a significant inhibition of cell proliferation ($p<0.0001$) and an induction of cell death ($p<0.001$), probably caused by significantly [SL1] reduced levels of phosphorylated c-Met. *In vivo* ARQ-197 treatment of JJN3 tumour-bearing mice resulted in a significant reduction in tumour burden ($p<0.001$), where tumour infiltration of the bone marrow was reduced by approximately 43% (96±4.9% vehicle *vs* 55±20% ARQ-197 treatment). ARQ-197 treatment also significantly prevented the formation of myeloma-induced bone lesions ($P<0.001$) and the loss of trabecular bone ($p<0.01$) compared to vehicle treated JJN3-tumour bearing mice. Dynamic histomorphometry showed ARQ-197 treatment prevented significant decreases in the mineralising bone surface ($p<0.001$), the mineral apposition rate ($p<0.01$), the bone formation rate ($p<0.01$), and prevented complete loss of osteoblasts on the cortico-endosteal bone surface compared to the vehicle group.
Summary/Conclusions: In summary, these results suggest that ARQ-197 could be a promising therapeutic in myeloma patients who express high levels of HGF, leading to both a reduction in tumour burden and an inhibition of myeloma-induced bone disease.

THE GENETIC LANDSCAPE OF THE MURINE 5T MODELS FOR MULTIPLE MYELOMA

K. Maes[1,*], B. Boeckx[2], K. De Veirman[1], E. Menu[1], K. Vanderkerken[1], D. Lambrechts[3], E. De Bruyne[1]
[1]Hematology and Immunology, Vrije Universiteit Brussel, Brussel, [2]Department of Oncology, VIB Center for Cancer Biology, [3]Department of Oncology, VIB Center for Cancer Biology, Leuven, Belgium

Background: Multiple myeloma (MM) is a plasma cell malignancy which remains incurable in most cases. This is mainly attributed to the large genetic and clonal heterogeneity between patients and within individual patients. The mutational landscape of MM patients has led to the discovery of several potential driver mutations and copy number alterations reflecting this genetic heterogeneity. Genetic lesions affecting RAS/MAPK and NF-KB pathways, apoptosis and cell cycle signaling are the most commonly found in patients. Moreover, mutations disturbing the DNA damage response are linked with poor prognosis.
Aims: The use of suitable murine MM models is important to gain understanding of the functional consequences of the genetic heterogeneity observed in patients. However, to date, the genetic landscape of murine MM models have not been analyzed. Our aim of this study is to analyze the genetic landscape of the 5T murine models for MM.
Methods: In this study, we used the 5T2, 5T33vv and 5TGM1 murine models for MM. As control samples, we used C57Bl/KaLwRij and C57Bl/6J germline DNA. We analyzed the copy-number alterations and the mutational landscape using shallow whole genome sequencing and whole exome sequencing.
Results: Among the tested models, the 5T2 model displayed the most copy number alterations. Over the entire genome, 11% and 17% showed copy number alterations for the 5T33vv and 5TGM1 of which 6% is shared reflecting their clonal relationship. Overall, the copy-number alterations affects genes involved in RAS/MAPK, PI3K/AKT1 and JAK/STAT signaling, DNA damage response, cell cycle and epigenetic regulation. Exome sequencing revealed the presence of 417, 407 and 314 non-synonymous mutations and 8, 14 and 24 indels in the 5T33vv, 5TGM1 and 5T2 models, respectively. Moreover, a statistically significant overlap of mutated genes between the 5T33vv and 5T2 models and multiple myeloma patients from two large cohorts published by Lohr *et al.* and Walker *et al.* was observed ($p<1E-8$). Similar to MM patients, we identified damaging mutations in Trp53, Rb1, Pik3ca, Fat3, Kdm6a and Nf1.
Summary/Conclusions: In summary, our results show that the disturbed genetic landscape of the 5T models shows heterogeneity and a partial overlap with multiple myeloma patients. The genetic defects affect pathways known to be involved in multiple myeloma cell survival. The 5T models thus represent reliable models to study the characterized genetic defects.

CHARACTERIZING THE CONTRIBUTION OF BONE MARROW STROMA-DERIVED IL-6 TO MYELOMA GROWTH AND RESISTANCE

T. Csikos[1,*], H.-J. Prins[1], E. Drent[1], P. Poddighe[2], S. Zweegman[1], T. Mutis[1], R. Groen[1]
[1]Hematology, [2]Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands

Background: The bone marrow niche is a specialized microenvironment, which allows for the survival, growth and differentiation of hematopoietic stem and progenitor cells. This niche also provides the optimal growth conditions for hematological malignancies, such as multiple myeloma (MM). A complex interaction between cytokines, adhesion molecules, cell receptors and their ligands provides the MM plasma cells with survival signals and contribute to therapy resistance.
Aims: To unravel the role of the bone marrow mesenchymal stem/stromal cells (BMMSCs) in MM cell growth, progression and drug resistance.
Methods: Hypothesizing that the interaction between MM cells and the BMMSCs is bidirectional, we have compared BMMSCs from healthy individuals, mgUS, and MM patients and used our "humanized" bone marrow-like model to characterize the molecular impact of MM cells on BMMSCs. Finally, we have validated targets by generating HS-5 knock-out lines using CRISPR/Cas9 targeting.
Results: Analyzing the BMMSCs of healthy individuals,mgUS, and MM patients, as well as BMMSCs impacted by MM in our humanized bone marrow-like model, allowed us to confirm established disease biomarkers (*e.g.* IL-

6, HGF, IGF and GDF15) and identify novel mediators of MM disease progression and bone disease. To further elucidate the role of IL-6 in BMMSC-induced growth of MM plasma cells and drug resistance, we have established HS5 stromal cell lines that upon CRISPR/Cas9 targeting have reduced or no expression of IL-6. RNA sequencing analysis of these cells revealed IL-6 to be a master regulator of cytokine production (e.g. IL-1B, CXCL8, CSF2 and CSF3). Disruption of the IL-6 gene did not result in a reduced growth rate of the IL-6 deficient stromal cells as compared to wildtype. Using the compartment specific bioluminescent imaging co-culture system, where luciferase gene-marked MM cells are co-cultured with non-marked stromal cells, we have documented a contribution of the stromal cells to both growth and drug resistance to known chemotherapeutics (*e.g.* bortezomib, doxorubicin) of MM cells. Using this same co-culture system we compared wildtype and IL-6 deficient stroma. Although disruption of IL-6 in the stromal cells resulted in a reduced proliferation of MM cells and stromal cell mediated drug resistance, it did not entirely reverse these stroma-mediated effects.

Summary/Conclusions: Taken together these data suggest that although IL-6 is one of the most deregulated genes in MM-derived BMMSCs, it certainly is not the sole contributor to BMMSC-induced MM cell growth and drug resistance.

E1222

THE PAN-PIM KINASE INHIBITOR, PIM447, POTENTLY SYNERGIZES WITH POMALIDOMIDE PLUS DEXAMETHASONE IN PRECLINICAL IN VITRO AND IN VIVO MODELS OF MULTIPLE MYELOMA

T. Paíno[1,2,*], L. San-Segundo[1,2], S. Hernández-García[1,2], L. González-Méndez[1,2], E.M. Algarín[1,2], M. Martín-Sánchez[1], M.-V. Mateos[2], M. Garayoa[1,2], E.M. Ocio[1,2]
[1]Centro de Investigación del Cáncer (CIC-IBMCC), [2]Complejo Asistencial Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: PIM kinases are a family of serine/threonine kinases recently proposed as therapeutic targets in multiple myeloma. Recent work from our group has shown the dual antimyeloma and bone-protective effects of the pan-PIM kinase inhibitor, PIM447, and its *in vitro* synergism with current standards of care. Since myeloma remains an incurable disease, the preclinical evaluation of new drug combinations is of utmost importance, in order to support the development of future clinical trials. In this scenario, effective all-oral combinations are particularly attractive.

Aims: The aim of the present work has been the evaluation of the efficacy and mechanism of action of the all-oral triple combination PIM447 + pomalidomide + dexamethasone in preclinical *in vitro* and *in vivo* models of multiple myeloma.

Methods: *in vitro* cytotoxicity of PIM447, pomalidomide and dexamethasone alone or in double and triple combinations was evaluated on myeloma cell lines. The combination index (CI) was calculated with Calcusyn software based on results from MTT assay. Effects on apoptosis and cell cycle were evaluated by flow cytometry. Glucose uptake was analyzed by incubation with 2-NBDG. The mechanism of action was explored by analysis of different protein levels by western blot. Finally, a plasmacytoma model in CB17-SCID mice was employed for *in vivo* studies.

Results: Triple combination PIM447 + pomalidomide + dexamethasone showed a strong synergism (CI<0.3) in MM1S and RPMI-8226 cell lines. The clear reduction of cell viability promoted by this combination was due to induction of apoptosis and cell cycle arrest at G_0-G_1 phase. Accordingly, cleavage of caspase 3 and PARP, as well as reduction of cyclin D2 was observed by western blot. In addition, triple combination inhibited mTORC1 as shown by decreased levels of p4EBP1 and pS6RP. Interestingly, treatment with PIM447 + pomalidomide + dexamethasone remarkably reduced the levels of the glucose metabolism-associated enzime hexokinase II and also reduced glucose uptake by cells. Finally, the efficacy of this combination was confimed in a plasmacytoma model in CB17-SCID mice, where it clearly reduced tumor growth as compared to single and double treatments.

Summary/Conclusions: Our preclinical data suggest that myeloma patients could benefit from treatment with the triple combination PIM447 + pomalidomide + dexamethasone and would support future clinical trials with this combination.

E1223

EXPRESSION OF CD38 AND ECTOENZYMES OF THE ADENOSINERGIC PATHWAYS IN MYELOMA BONE NICHE: A RATIONAL BASIS FOR THE USE OF DARATUMUMAB TO TARGET OSTEOCLAST FORMATION IN MULTIPLE MYELOMA

F. Costa[1,*], D. Toscani[1], A. Chillemi[2], V. Quarona[2], M. Bolzoni[1], V. Marchica[1,3], R. Vescovini[1], C. Mancini[4], E. Martella[4], N. Campanini[4], C. Schifano[5], S. Bonomini[5], F. Accardi[1,5], A. L. Horenstein[2], F. Aversa[1,5], F. Malavasi[2], N. Giuliani[1,3,5]
[1]Medicine and Surgery, University of Parma, PARMA, [2]Medical Sciences and CeRMS, University of Torino, TORINO, [3]CoreLab, [4]Pathology, [5]Hematology and BMT Center, Azienda Ospedaliero-Universitaria di Parma, PARMA, Italy

Background: Bone disease is the hallmark of multiple myeloma (MM). It is known that MM cells express CD38 and that a recently developed human anti-CD38 monoclonal antibody, Daratumumab (DARA), induces and mediates MM cell killing. However, the expression of CD38 and other functionally related ectoenzymes in the bone niche of MM patients and the potential effects of DARA on bone cells are still unknown.

Aims: The aim of this study was to define the expression profile of CD38, CD31, CD39, CD73 and CD203a on MM and bone niche cells. Then, the effect of DARA on bone cells was evaluated by *in vitro* osteoclastogenesis.

Methods: In order to evaluate the expression profile of CD38 and the ectoenzymes, we firstly performed immunohistochemical analysis on bone biopsies in a cohort of 37 patients with MM and 14 with monoclonal gammopathy of uncertain significance (MGUS). The same antigens were analyzed by flow cytometry on primary MM cells, mesenchymal stromal cells (MSC), osteoblasts (OB), monocytes and osteoclasts (OC). Then, we tested DARA effects, in the presence or absence of *All-trans* retinoic acid, compared with human IgG isotype control, on OC differentiation from either $CD138^-$ cell fraction or purified MM bone marrow (BM) $CD14^+$ cells. We also investigated the effect of microvesicles isolated from a MM cell line treated with DARA or the human IgG isotype control, on OC differentiation.

Results: MM cells showed a high expression of CD38 and were positive for CD31, CD39, CD73 and CD203a at variable levels. However, we did not find any significant difference in the expression of CD38 and related ectoenzymes between MM andmgUS patients. CD38 was expressed by monocytes and early OC progenitors but not by OB, mature OC and MSC, that were positive for CD73 and CD203a. Indeed, CD38 was lost during OC differentiation. Consistently, we found that DARA reacts with CD38 expressed by monocytes and its binding inhibits early *in vitro* osteoclastogenesis from total mononuclear cells. *All-trans* retinoic acid treatment increased the inhibitory effect of DARA on OC formation.

Summary/Conclusions: Our data suggest that DARA inhibits osteoclastogenesis, targeting monocytes and early progenitors. These observations provide a rationale for the use of an anti-CD38 antibody-based approach as treatment for MM-induced osteoclastogenesis.

E1224

TRIM33 IS A POTENTIAL TUMOR SUPPRESSOR IN MULTIPLE MYELOMA

C.K. Johnston[1,*], L.J. Crawford[1], K.I. Mills[1], A.E. Irvine[1]
[1]Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom

Background: Multiple myeloma (MM) continues to be an incurable plasma cell neoplasm, regardless of recent therapeutic advances. The success of proteasome inhibitors in MM validates the ubiquitin proteasome system (UPS) as a therapeutic target. Using a UPS-specific microarray (PIQOR) we identified aberrant expression of an E3 ligase TRIM33 (tri-partite motif containing protein 33) in MM. TRIM33 has previously been identified as a tumor suppressor in chronic myelomonocytic leukaemia and hepatocellular carcinoma.

Aims: The aim of this study was to examine TRIM33 expression and to investigate its role as a potential tumor suppressor in MM.

Methods: Western blotting and qPCR were used to analyse TRIM33 expression at basal level and following knockdown in four MM cell lines representing a range of MM translocations; JJN3 t(14;16), U266 t(11;14), KMS-18 t(4;14), OPM-2 t(4;14). TRIM33 knockdown was performed using shRNA pLKO lentiviral plasmids. CellTiter-Glo® was used to determine cell viability following knockdown and drug treatments. Partek ®Genomics Suite was used to analyse publically available datasets to look at TRIM33 expression and correlation with survival in subsets of newly diagnosed MM; GSE19784 (N=320) and GSE2658 (N=551). qPCR was used to validate the changes in expression of the TRIM33 gene signature.

Results: Compared to normal bone marrow, lower expression of TRIM33 was observed at both gene and protein level (p=0.03) in the t(4;14) cell lines, KMS-18 and OPM-2. Conversely, expression was found to be high in the non t(4;14) cell lines, JJN3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression did not alter cell viability in the t(4;14) cell lines. However, cell viability was significantly increased in JJN3 (P<0.04) and U266 (P<0.05). Analysis of a publically available dataset, GSE19784, showed lower levels of TRIM33 present in patients with a t(4;14) compared to other MM subtypes, particularly t(6;14) (p≤0.004) and hyperdiploid cluster (p≤0.03). Low TRIM33 expression has also been associated with poor overall survival (GSE2658; p=0.00034). Forty-seven genes associated with TRIM33 expression in non t(4;14) MM were identified; these genes were analysed using QUADrATiC tools connectivity mapping to identify FDA approved agents predicted to enhance the TRIM33 gene signature. One of the top enhancers identified was the tyrosine kinase inhibitor (TKI) Imatinib. The OPM-2 cell line showed greatly increased sensitivity to Imatinib compared to other cell lines (IC50: 0.8 μM *vs* 20 μM). Similar effects were observed with second generation TKIs, Dasatinib (IC50: 0.003 μM *vs* >1μM) and Nilotinib (IC50: 0.08 μM *vs* >1μM). An increase in genes associated with TRIM33 expression in non t(4;14) subtypes was also observed following Imatinib treatment.

Summary/Conclusions: We have shown that TRIM33 exhibits lower expression in t(4;14) cell lines, compared to non t(4;14) cell lines and that knockdown of TRIM33 increased the viability of non t(4;14) cell lines. This suggests that TRIM33 may act as a tumor suppressor in MM and that expression is dysregulated in a subset of MM. Connectivity mapping identified Imatinib as an

enhancer of the TRIM33 signature that potently decreased the viability of the OPM-2 cell line. This study suggests that enhancing the TRIM33 gene signature could potentiate the tumor suppressive effect of TRIM33 and identify novel therapies for this subset of MM.

E1225

LONG NON-CODING RNAS EXPRESSION HETEROGENEITY AND FUNCTIONAL INVOLVEMENT IN MULTIPLE MYELOMA

Background: Increasing amount of evidence indicates that deregulation of long non-coding RNAs (lncRNAs) is a common feature of cancer and therefore, its investigation may uncover new molecular oncogenic mechanisms. In multiple myeloma (MM), altered expression of small number of lncRNAs has been associated with decreased disease-free and overall survival, suggesting that these elements may play a more important role in MM than previously anticipated. Nevertheless, an extensive high-throughput analysis that characterizes the deregulation of lncRNAs in MM has not yet been performed.
Aims: We aim to characterize the lncRNA transcriptome of MM and its heterogeneity, and determine whether altered lncRNAs have a functional involvement in this disease.
Methods: Paired-end strand-specific RNA sequencing (ssRNA-seq) was performed in 38 purified plasma cell (PC) samples from MM patients, as well as in 5 tonsil PCs (TPCs) and in 3 bone marrow PCs (BMPCs) of healthy donors as controls. We also performed ssRNA-seq of populations from B cell differentiation (Naïve, Germinal Center, Memory and PC). To study the heterogeneity of lncRNAs expression we performed sample level enrichment analysis (SLEA), in which each individual lncRNA was compared to BMPCs. To determine the epigenetic regulation of lncRNAs we used whole-genome bisulfite sequencing and CHIP-seq. shRNA-mediated knockdown using 2 different shRNAs and MTS (cell proliferation) and annexin V (cell death) assays were utilized to study the functional effect of lncRNA overexpression.
Results: We identified 40.552 novel lncRNAs in MM samples that were present in at least 3 of the 38 patients. Principal component analysis demonstrated that TPCs and BMPCS cluster separately, suggesting that, in spite of being the same cell type, their transcriptomes are very different. We observed that the expression of lncRNAs was more heterogeneous than that of coding genes. More importantly, SLEA showed 11.067 lncRNAs that were overexpressed and 5.601 underexpressed in >40% of patients. Thus, the number of deregulated genes analyzed by SLEA was much larger than the 70 lncRNAs that appeared as deregulated when all MM were compared to BMPCs, demonstrating the relevance of studying the heterogeneity in this disease. To determine the functional role of heterogeneously altered lncRNAs in the biology of MM cells we focused on the study of *LINC-SMILO* (*Specific Myeloma INtergenic LOng noncoding RNA*), a lncRNA that it is overexpressed in ~ 40% of MM patients and not at different stages of B-cell differentiation. DNA methylation analysis demonstrated that CpGs located upstream of *LINC-SMILO* showed a significant hypomethylation inmgUS, that was even more pronounced in MM samples. We also have observed a gain of active chromatin modifications in the promoter region of *LINC-SMILO* in MM patient samples. These data suggest that epigenetic mechanisms, namely DNA hypomethylation and the gain of active histone modifications, may be the cause of *LINC-SMILO* overexpression in MM. Knockdown of *LINC-SMILO* in 3 different cell lines (MM.1S, MM.1R and KMS-11) resulted in reduced proliferation and induction of apoptosis, indicating this lncRNA is essential for the survival of MM cells.
Summary/Conclusions: All together, these data demonstrate that alteration of lncRNAs is an important and unexplored feature of MM. Moreover, overexpression of *LINC-SMILO* is required for the survival of MM cells and could represent a potential therapeutic target for the treatment of this disease.

E1226

ROLE OF EPHA3 IN MULTIPLE MYELOMA: A PERSPECTIVE FOR A NOVEL TARGET THERAPY?

Background: The tyrosine kinase Eph receptor A3 (EphA3) has recently emerged as a potential therapeutic target, since it resulted to be overexpressed in many cancers, including some hematological malignancies (Keane *et al.* 2012). Furthermore, EphA3 has been found overexpressed not only in neoplastic cells, but also in the microenvironment of different human cancers, where its targeting inhibits tumor growth by disrupting supportive stroma and vasculature (Vail *et al.* 2014).
Aims: Due to the absence of relevant information about the role of EphA3 in multiple myeloma (MM), we aimed to evaluate the expression of this molecule in primary bone marrow plasma cells (BMPCs) from MM patients and MM cell lines compared to healthy controls (HCs). In addition, using a "loss of function" approach by mRNA silencing and an anti-EphA3 monoclonal antibody (EphA3mAb), we studied *in vitro* plasma cells (PCs) viability and movement. Finally, we analysed the *in vivo* effects of EphA3mAb in a MM mouse xenograft model.
Methods: EphA3 mRNA and protein where investigated in 15 MM BMPCs, 11 MM cell lines and 10 HCs by qRT-PCR and flow cytometry. The effects of EphA3 targeting by lentiviral RNA silencing (shRNA) and anti-EphA3mAb on PC trafficking and viability were studied by adhesion assay on fibronectin and on bone marrow stromal cells (BMSCs), invasion assays and proliferation MTS assay, respectively. Gene expression profiling (GEP) was performed in shEphA3 *versus* shControl cells. Furthermore, the effects of EphA3mAb were analysed in a MM xenograft model by measuring tumor size and by assessing angiogenesis, proliferation and apoptosis rate on tumor biopsies using immunohistochemistry (anti-CD31, anti-ki67 and TUNEL assay, respectively). Statistical significance was determined by the t-test or One-way ANOVA analysis.
Results: EphA3 was found overexpressed in primary MM BMPCs and MM cell lines when compared with HCs (figure 1A-B). The EphA3 loss of function by siRNA and by EphA3mAb significantly inhibited *in vitro* the ability of MM PCs to adhere to fibronectin, to BMSCs and to invade (figure 1C-E), without affecting cell proliferation and viability (data not shown). GEP showed that knockdown of EphA3 modulated some molecules that regulate adhesion, migration and invasion processes. Importantly, the treatment with EphA3mAb *in vivo* significantly reduced tumor size and inhibited angiogenesis, as revealed by decrease of CD31+ vessels at immunohistochemistry (data not shown).

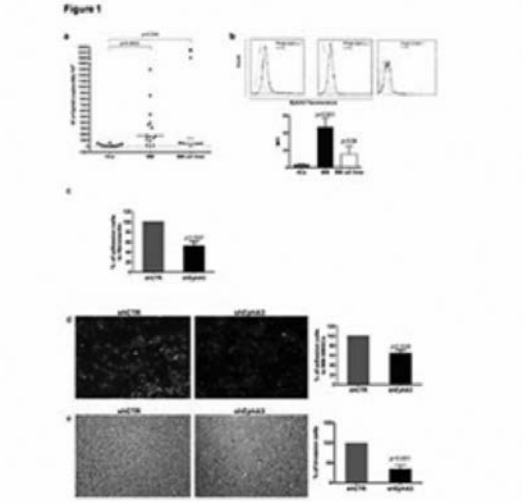

Figure 1. EphA3 expression was verified by absolute quantitative qRT-PCR (normalized to Abelson=ABL) in bone marrow plasma cells (BMPCs) from 5 healthy controls (HCs), 15 MM patients and 11 MM cell lines (◆ SKMM1, ● KMS-11, ▼ KMS-12-BM, ◇ KMS-18, * KMS-34, ⁄ KMS-28, ▲ MM1S, ■ JJN3, ⁷ U266, ⁻⁺ RPMI-8226, □ OPM-2; β-actin = loading control; (lines inside scatters represent the median values)] (a) and by cytometry analysis in PCs from a representative MM patient, HC and MM cell line (b). Mean fluorescence intensity (MFI) as mean ± SD of 3 HCs, 5 MM BMPCs and 4 MM cell lines. shEphA3 and shCTR cells were tested in adhesion to fibronectin (FN; c) and to MM bone marrow stromal cells (BMSCs; d) and Matrigel® invasion test (e). Data are presented as percentage of the respective controls (mean ± SD of triplicates from 3 independent experiments) for viability, proliferation, adhesion to FN and invasion assays. For the adhesion to BMSCs data are presented as percentage of the respective controls and are shown as means ± SD of n=3 experiments on 3 BMSCs by analysing five random fields for each experiment.

Summary/Conclusions: Our findings suggest that EphA3 is a novel regulator of MM PC trafficking, in part via effects on adhesion and invasion; its targeting using EphA3mAb inhibits tumor growth, possibly by reducing angiogenesis, though other possible mechanisms of tumor death cannot be excluded. These data, together with the favourable clinical properties of a humanized EphA3mAb reported in a phase I trial on acute myeloid leukemia and myelodysplastic syndrome (Swords *et al.* 2016), support EphA3 targeting as a new potential therapeutic opportunity for MM that would warrant to be further investigated.

E1227

PROGNOSTIC SIGNIFICANCE OF AMP1Q21 IN MULTIPLE MYELOMA

T. Abramova[1,*], T. Obukhova[1], L. Mendeleeva[1], O. Pokrovskaya[1], E. Gribanova[1], M. Nareyko[1], L. Grebenyuk[1], O. Votyakova[2], M. Solovev[1], M. Firsova[1], I. Nakastoev[1], A. Grachev[1], M. Kanaeva[1], A. Danilina[1], S. Kulikov[1], M. Rusinov[1], V. Savchenko[1]
[1]Hematology Research Center, [2]N.N.Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Multiple Myeloma (MM) is a genetically heterogeneous and complex disease with widely diverging survival times from months to years. Amplification of locus 1q21 (amp1q21) is among the most commonly reported genetic abnormalities in MM, but its prognostic value remains unclarified.
Aims: To define the frequency of amp1q21 in MM and its correlation with other chromosomal abnormalities, clinical course and prognosis.
Methods: In 134 patients (pts) with newly diagnosed MM from December, 2009 to March, 2016, 67 male and 67 female, median age 57 years (30-81), we performed FISH with locus-specific and centromere DNA probes (XL 1p32/1q21, XL IGH plus, XL t(11;14), XL t(4;14), XL t(14;16), XL t(14;20), XL t(6;14), XL cMYC BA, XL 5p15/9q22/15q22, XL P53 (MetaSystems), D13S25 (Cytocell). Induction therapy with bortezomib-based courses was initiated for 131 pts, 3 pts with smoldering MM remained under observation. Response was evaluated according to the IMWG criteria for 127 pts, because 4 pts died in induction. 48 pts were underwent ASCT. The median follow-up of group was 19.3 months (3,2 – 77,4). Progression was diagnosed in 69 pts, in 12 of them FISH-analysis was performed also in disease progression.
Results: Chromosomal aberrations were revealed in 133 of 134 (99%) pts. TIgH/14q32 were detected in 42.5% (57/134), hyperdiploidy in 57.5% (77/134), hypoploidy in 2.4% (3/134) pts. In 11.2% (15/134) a concurrent tIgH/14q32 and a trisomy were found. The IgH translocations t(11;14), t(4;14), t(14;16), t(14;20), t(6;14) were observed at a frequency of 16.4%, 12.7%, 3.7%, 2.2%, 0.7% respectively, chromosomal partner is not found in 6.7%. Del(13q) was detected in 40.3% (54/134), del(17p) in 12.7% (17/134), tcMYC/8q24 in 17.2% (23/134). Amp1q21 was detected in 39.6% (53/134). We identified 3 copies of 1q21 in 32 (60.4%) and>3 copies 1q21 (4-7) in 21 (39.6%) pts. Cases with amp1q21 had a high incidence of del(13q) (OR=2.71 (1.32-5.55); p=0.006) and t(4;14) (OR=4.49 (1.47-13.51); p=0.005), as well as higher LDH levels (OR=2.27 (1.09-4.72); p=0.027). From 12 pts investigated in progression amp1q21 was found in 9 pts (75%): in 2 cases amp1q21 was not found at diagnosis and was revealed in disease progression only; in 7 cases - amp1q21 was detected at diagnosis and in progression, and its copy number did not change. The difference in response after induction between pts with or without amp1q21 was not statistically significant: CR – 11.8% *versus* 14.5%; VGPR –39.2% *versus* 27.6%; PR –37.2% *versus* 27.6%; therapy resistance 11.8% *versus* 30,3% (p=0.07). Pts with amp1q21 had significantly worse 5-year overall survival (OS) (43.5% *vs* 79.4%; p=0.07). According to copy number of 1q21 the 5-year OS pts carrying 3 or >3 copies of 1q21 were 67.3% and 20.9% (p=0.0016) (Figure 1). On multivariate analysis>3 copies of amp1q21 (HR=4.29, p=0.0094), tcMYC/8q24 (HR=6.51, p=0.0082), del(17p) (HR=3.46, p=0.007) were found to be an independent adverse predictors of shorter OS.

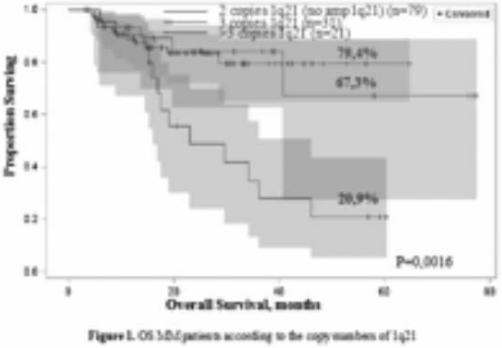

Figure 1.

Summary/Conclusions: Our results show that amp1q21 has a significant impact on OS MM pts in cases of more than 3 copies of locus only. In cases of 3 copies of 1q21 OS pts is comparable with OS in group without amp1q21. Amp1q21 can appear in the course of MM, therefore FISH-analysis of locus 1q21 should be performed at diagnosis, as well as in disease progression.

E1228

ADAPTIVE IMMUNE RESPONSE IN PLASMA CELL DYSCRASIAS: IMMUNE PROFILING AND DETERMINATION OF CIRCULATING B CELL LEVELS AS A SURROGATE ASSAY FOR BONE MARROW TESTING

S. Drain[1,*], P. Egan[1], I. Deighan[2], P. Elder[3], T. Bjourson[1], F. McNicholl[3], M. Bowers[4], C. Morris[3], D. Alexander[1]
[1]Stratified Medicine, C-tric, Ulster University, [2]Clinical Biochemistry, [3]Haematology Department, Altnagelvin Hospital, Derry, [4]Haematology Department, Ulster Hospital, Belfast, United Kingdom

Background: Immune paresis is commonly identified in patients with plasma cell dyscrasias (PCD). Often, in newly presenting multiple myeloma (MM), it is associated with intractable infections for which the patient first seeks medical help. Furthermore, recent evidence suggests the importance of assessing levels of bone marrow (BM) derived B cells for risk stratification of MM patients as reduced levels of B-cells in the BM have been associated with poorer outcomes and reduced progression free survival[1]. This cellular measure of adaptive immune function (ie: B cell enumeration) is, however, seldom analysed in the peripheral blood (PB) of patients with PCD.
Aims: This study was designed to examine measures of the adaptive immune response in PCD patients, by measuring relative and absolute numbers of T, T cell subset, B, NK and NKT cells at different stages of PCD, and to determine if the PB B-cell component can act as a surrogate marker for B cell enumeration in the BM.
Methods: PB and BM lymphocyte subset analysis was performed on samples obtained from a range of PCD patients (n=70) using directly conjugated monoclonal antibodies (MAB) and multicolour flow cytometry, carried out on a FACSAria III cell sorter (BD, Oxford, UK). Serum protein electrophoresis was performed to identify and quantify paraprotein, and uninvolved Ig levels were quantified immunoturbidometrically. sFLC were estimated using the Freelite assay on the SPAplus instrument (Binding Site, Birmingham, UK).
Results: Data is presented on 102 PB samples obtained from 70 PCD patients at different stages of disease, including monoclonal gammopathy of undetermined significance (MGUS), smoldering myeloma (SMM), and MM at diagnosis (MMD), throughout treatment (MMT) and at relapse (MMR). Quantification of circulating lymphocyte subsets showed reduced, absolute, numbers of B cells (56/102), T cells (19/102), T_H cells (32/102), CTLs (17/102), NK cells (32/102) and NKT cells (72/102). Furthermore, these reduced B cell levels were more frequently seen in the MMD and MMT groups (50% of samples) compared with the other PCD groups (10-25% of samples). Lymphocyte subset analysis was also performed on paired PB and BM samples from 14 patients with MM and a significant, positive, correlation was seen between relative numbers of B cells in both PB and BM ($p<0.0001$, $r^2=0.94$). No clearcut correlations were found between reductions in uninvolved Ig or sFLC levels, and numbers of cells involved in the adaptive immune response.
Summary/Conclusions: The results presented here are further evidence of immune paresis in PCD with specific effects seen at the cellular level. The highest frequency of reduction was in B lymphocytes and NKT cells, in keeping with reduced levels of circulating uninvolved Ig levels, followed by T cells, particularly T_H cells which have a crucial role in B cell Ig production. Relative B cell levels in BM were significantly correlated with B cell levels in PB and we suggest that monitoring of B cell levels in the PB of PCD patients may serve as a surrogate assay for enumeration of B cells in BM.

E1229

NOVEL MONOCLONAL ANTIBODY THERAPY TARGETING CD26 IN MULTIPLE MYELOMA

H. Nishida[1,*], H. Suzuki[1], M. Hayashi[1], M. Sakamoto[1], T. Yamada[1]
[1]Pathology, Keio University, School of Medicine, Tokyo, Japan

Background: Bone disease is a hallmark of multiple myeloma (MM) and targeting osteoclasts (OCs) to alleviate bone destruction is a component of the standard care for MM. CD26 is a 110-kDa cell surface glycoprotein with DPPIV enzyme activity and has well-defined roles in T cell activation and several tumor developments, including malignant lymphoma. However, little is known about the role of CD26 in regulating bone remodeling.
Aims: In this study, we examine the CD26 expression in human normal OCs and OCs of MM patients. We explore the function of CD26 in osteoclastgenesis (OCG) and investigate the effects of humanized anti-CD26 monoclonal antibody (CD26mAb) on human OCG. We further define the molecular targets of CD26 signaling cascade in OCG and explore the therapeutic potential of CD26mAb for treating MM.

Methods: Human BM-MNCs derived from normal human subjects or MM patients were cultured with M-CSF plus sRANKL with or without CD26mAb for OC formation for TRAP staining and functional assay. To assess the mechanisms of action of CD26mAb on OCG, RANK signaling proteins were examined by immunoblotting.
Results: CD26 is expressed on normal human OCs and is intensely expressed on activated OCs in MM. M-CSF and sRANKL induced human OC differentiation, in association with CD26 expression on monocyte-macrophage lineage cells. CD26 expression was accompanied by increased phosphorylation of MKK3/6 and p38MAPK, which is crucial for early human OC differentiation with its downstream activation of microphthalmia-associated transcription factor (mi/Mitf), which plays an important role in OC functions. CD26mAb decreased the number of multinucleated OCs (>3 nuclei) by TRAP/CD26 staining and down-regulated the secretion of TRAP-5b and type 1 collagen. It decreased the size of OCs and the number of nuclei per OC, with significantly defective bone resorption activity. It was revealed that in the presence of CD26mAb, when it bound to CD26 on OC precursor cells, only MKK3/6-p38MAPK phosphorylation pathway was specifically, rapidly inactivated and subsequently, its downstream mi/Mitf phosphorylation was persistently inhibited. Thus, OC maturation with its bone resorption was impaired by suppressing the expression of TRAP and OC fusion proteins. In contrast, MKK3/6-p38MAPK-mi/Mitf was not phosphorylated at all in mature OCs after RANKL stimulation, regardless of the absence or presence of CD26mAb. These results suggest that CD26mAb blocked RANKL induced p38MAPK phosphorylation in OC precursor cells, but not in OCs. The activation of other MAPKs including ERK and SAPK/JNK, or NFκB was rapidly induced in response to RANKL both in OC precursor cells and OCs, regardless of the absence or presence of CD26mAb. Moreover, CD26mAb did not directly affect mature OC functions. Next, although CD26mAb did not demonstrate direct inhibition of proliferation of MM cells, to further investigate the role of CD26 in MM cells in the BM, co-cultures of 11 MM cell lines with CD26-stained OCs were performed. We examined the expression of CD26 in MM cells. Although CD26 expression was only slightly detected in any of MM cell lines in mono-culture, CD26 expression level was upregulated in all MM cell lines, co-cultured with OCs by flow cytometry and immunohistochemistry. CD26 protein level in these cell lines was also increased by immunoblotting or ELISA. To further explore the CD26 expression in the BM of MM patients, we performed immunohistochemical staining on decalcified biopsy specimens. CD26/CD138 positive plasma cells were detected around CD26 positive OCs and certain endothelial vascular cells in several cases. Anti-myeloma efficacy of CD26mAb on MM cells, co-cultured with OCs was also revealed.
Summary/Conclusions: Our data imply that the blockade of CD26 signaling with CD26mAb impairs the development of human functional OCs. Targeting CD26 in both OCs and MM cells with CD26mAb may be a promising novel therapeutic strategy in MM-associated bone disease and MM progression.

E1230

KYNURENINE INHIBITS T-CELLS THROUGH THE ARYL HYDROCARBON RECEPTOR AT IDO-POSITIVE TUMOR MICROENVIRONMENT

S. Ninomiya[1,*], N. Nakamura[1], J. Kitagawa[1], S. Kasahara[2], T. Hara[1], K. Saito[3], M. Shimizu[1], H. Tsurumi[1]
[1]Hematology, Gifu University Graduate School Of Medicine, [2]Hematology, Gifu Municipal Hospital, [3]Internal Medicine, Gihoku Kosei Hospital, Gifu, Japan

Background: IDO is an intracellular enzyme proceed the essential amino acid tryptophan metabolism. Accumulation of tryptophan derivatives such as kynurenine blocks antigen-specific T-cell proliferation and induces T-cell death. A recent study indicated that kynurenine was an endogenous ligand of aryl hydrocarbon receptor (AhR), which is a ligand-dependent transcription factor well known to generate biological responses to dioxins. We previously showed that both IDO expression by tumor cells and high serum kynurenine levels correlate with poor prognosis in non-Hodgkin lymphoma patients. We also revealed that tumor IDO activity can inhibit CD19-specific CAR T-cell therapy through the action of tryptophan metabolites (*Blood*. 2015; 125(25): 3905-3916).
Aims: Therefore, we now focus on the AhR in T-cells to escape from IDO-positive tumor microenvironment.
Methods: We collected PBMCs from healthy blood donors, and bone marrow (BM) samples from multiple myeloma (MM) patients at first diagnosis. The cells were activated with anti-CD3 and anti-CD28 Abs. We measured the expression of AhR in activated T-cells using by flow cytometry. We then studied the effect of kynurenine on the proliferation and apoptosis of T-cells. To evaluate the effect of inhibiting AhR in T-cells, we used AhR inhibitor (CH-223191). Next, to assess the functional effects of tryptophan metabolites on the T-cells, we cocultured T-cells with GFP-transduced wild-type Raji cells or IDO-transduced Raji cells. After 72 hours, cells were stained with CD8 antibody to distinguish tumor (GFP+ CD8–) and T-cells (GFP- CD8+).
Results: We found that the range of AhR expression in activated T-cells were from 4.5% to 38%. We found that kynurenine significantly inhibited the proliferation of T-cells with high expression of AhR. The percentage inhibition with kynurenine 25μM was 33%. While T-cells with low expression of AhR were not inhibited with even 50μM of kynurenine. We found that kynurenine was also associated with increased the apoptosis of T-cells with high AhR, as assessed by Annexin-V staining (percent Annexin-V positive and 7-AAD negative cells in 0 and 25 μM kynurenine was 11.8% and 36%, respectively). We found that CH-223191 could blocked the inhibitory effects of kynurenine on T-cells. We found that the percentage of T-cells with high AhR in culture with IDO negative and positive Raji cells was 46.7% and 61.4%, respectively, while the percentage of T-cells with low AhR was 41.6% and 39.4%. These data showed that only T-cells with high AhR were inhibited at IDO-positive tumor microenvironment. Next, we could generated the activated T-cells from 10 of 12 BM samples from MM patients. We found that there was a positive correlation between the expression of AhR and the proportion of plasma cells in BM (r=0.76, P=0.04) and clinical stage of MM. The mean expression of AhR in T-cells of stage2 and stage3 were 7.3% (3.3-11.6) and 19.5% (11.3-26.6), respectively.
Summary/Conclusions: Kynurenine produced by IDO, induce inhibitory signal in T-cells through the AhR. Anti-PD-1 and anti-CTLA-4 therapies, which block directly the inhibitory signal in T-cells, have been getting some clinical benefits against such as melanoma and Hodgkin lymphoma. Therefore, the AhR in T cells might be a target for IDO-positive hematological malignancies.

THE ANTI-MYELOMA ACTIVITY OF PERK KINASE INHIBITOR IN TARGETING MORE THAN 50 UPR-RELATED GENES INVOLVED IN THE PROLIFERATION OF MM CELLS

T. Bagratuni[1,*], E. Kastritis[1], N. Mavrianou[1], C. Liacos[1], E. Terpos[1], M. Dimopoulos[1]
[1]National and Kapodistrian University of Athens, Athens, Greece

Background: Due to the immunoglobulin production, multiple myeloma (MM) plasma cells are dependent on the unfolded protein response process (UPR), which controls protein production and ensures its proper translation and folding. A study by Michallet et al (2011) showed that knockdown of one of the three well-known arms of the UPR, PERK (protein kinase R (PKR)-like ER kinase) in MM cells resulted in autophagic cell death. This outcome indicated the important role of PERK activation for the metabolic shift of plasma cell to myeloma cell but also its ability to impede the apoptotic effect. In this study we used a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding region, while displaying ≥385 fold selectivity over c-kit, Aurora B, BRK and many other kinases.
Aims: In this study we aimed to use a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding region, while displaying ≥385 fold selectivity over c-kit, Aurora B, BRK and many other kinases.
Methods: We initially screened 25 CD138+ MM patients and 6 human myeloma cell lines (HMCLs) for PERK mRNA expression. Our results showed that PERK mRNA is highly expressed in almost all patients (5-10 fold higher than the mean PERK expression of HMCLs).
Results: To test the effect of GSK2606414 on the proliferation of MM cells, 4 HMCLs were treated with different doses of GSK2606414 at two time points (24 and 48 hours). Treatment of cells with 3-30μM GSK2606414 resulted in a dose-dependent inhibition of cell proliferation in all HMCLs ranging for 20-95% reduction of proliferative activity, thus, indicating the dependency of these cells on PERK activity. Treatment with GSK2606414 at 20μM in H929 and L363 HMCLs for 24 hours resulted 25% and 15% increase in apoptotic cells by Annexin-PI staining respectively compared to the untreated cells. However, the most important finding was a significant synergistic effect of GSK2606414 with bortezomib in these cells. Specifically when H929 and L363 cells were treated with 5nM bortezomib in combination with 20μM GSK2606414, synergistic effect was seen where apoptotic cells reached 99% and 77% respectively, compared to bortezomib-treated cells (87% and 42% respectively). In addition, the effect of GSK2606414 in combination with bortezomib in the proliferation of H929 and L363 cells was examined. As seen in the apoptosis assay, pretreatment with GSK2606414 for 2 hours prior to bortezomib treatment resulted in 40% and 30% reduced cell proliferation in H929 and L363 respectively compared to bortezomib only treated cells. Under ER stress conditions, the activation of ATF6 and PERK/eIF2α leads to the induction of ATF4 translation and results in the upregulation of CHOP. To determine the gene target effects of GSK2606414, ATF4 and CHOP mRNA expression levels were determined in H929 cell line after 24 hour of treatment. Treatment with GSK2606414 alone did not alter the expression levels of CHOP but reduced more than 50% the expression levels of ATF4. When combined with bortezomib CHOP and ATF4 levels were reduced 20% and 60% respectively while treatment with bortezomib alone increased the levels of CHOP and ATF4 by 50-100%. Changes in RNA expression of 84 UPR-related genes were analyzed in H929 cells. Specifically H929 cells were pre-treated with GSK2606414 and then subjected to ER stress conditions by treatment with tunicamycin (TM). After 24 hours of treatment, 50 genes were found to be transcriptionally regulated by 5-fold in response to TM-induce UPR activation. Thirty of these genes (ERN1, ERN2,XBP1, DDIT3, CEBPB, PPP1R15A, etc.) were downregulsted by >5 fold, whereas 10 of these genes (HERPUD1, EIF2AK3, CREB3L3, HSPA2, HSPA1B, etc.) were upregulated similarly.

Summary/Conclusions: In conclusion, given the on-target pharmacological effects of PERK inhibitor on MM, development of PERK inhibitors may offer a therapeutic advantage that would affect MM pathogenesis and treatment.

E1232

ENVIRONMENTAL CONTROL OF PLASMA CELL FITNESS IN MULTIPLE MYELOMA: MALIGNANT CO-OPTATION OF ARGININE AS NOVEL IMMUNO-METABOLIC CHECKPOINT

A. Romano[12,*], J. M. Garcia Manteiga[3], V. Simeon[4], L. Parrinello[2], L. Canziani[1], E. Milan[1], M. Ghizzinardi[1], D. Tibullo[2], C. Giallongo[2], P. La Cava[2], F. Cremasco[1], C. Conticello[5], P. Musto[4], F. Ciceri[6], F. Di Raimondo[2], S. Cenci[1]
[1]Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milano, [2]Division of Hematology, Azienda Ospedaliera Policlinico e Vittorio Emanuele di Catania, Catania, [3]Center for Translational genomics and BioInformatics, San Raffaele Scientific Institute, Milano, [4]Laboratory of Pre-clinical and Translational Research IRCCS, CROB Referral Cancer Center of Basilicata, Rionero in Vulture (Pz), [5]Division of Genetics and Cell Biology, Azienda Ospedaliera Policlinico e Vittorio Emanuele di Catania, Catania, [6]Department of Oncohematology, San Raffaele Scientific Institute, Milano, Italy

Background: The bone marrow (BM) environment plays a crucial role in the incurable plasma cell (PC) malignancy multiple myeloma (MM). Our previous work showed that autophagy is essential to sustain long-lived PC fitness, regulating Blimp-1, immunoglobulin (Ig) production and ATP availability (Pengo, 2013) and that MM is addicted to the autophagy receptor SQSTM1/p62 (Milan, 2015). Among putative pro-tumoral players are immunosuppressive BM-derived high-density neutrophils (HDNs), but their role in MM is unknown.
Aims: We hypothesized that in MM HDNs sustain PC fitness sustaining p62 through environmental arginine deprivation.
Methods: We integrated diverse unbiased and hypothesis-driven approaches: (1) gene expression profiles (GEP) of patient-derived circulating HDNs (60 MM, 30mgUS, 30 healthy controls), (2) metabolomic profiling by UHPLC/GC-MS of *ad hoc*-collected BM and peripheral plasma (16 MM, 17 smoldering MM, 30mgUS, 29 controls), and (3) functional and expression *in vitro* studies on human MM cell lines. We validated our observations in primary MM cells using bioinformatic analysis of transcript expression levels detected by RNA sequencing (RNAseq) available from the open-access, public clinical and molecular database, the CoMMpass Researcher Gateway (RG, (https://research.themmrf.org, v IA8, n=549).
Results: *In vitro*, selective and progressive arginine deprivation (range 1000-0 μM) in four MM cell lines (MM.1S, U266, OPM2 and RPMI8826) activated the GCN2/CHOP axis, resulting in increased p62 and Blimp-1 expression, increased ATP availability and immunoglobulin production. Conversely, stable lentiviral p62 silencing significantly reduced Blimp-1 and ATP, and led to complete extinction of MM cell lines within 10 days of culture. Bioinformatic analysis of MMRF-Encompass trial data showed a positive correlation between p62 and Blimp-1 expression (r^2=0.92, p<0.0001). Both high Blimp-1 and p62 transcripts predicted shorter progression-free survival at 24 months (4.56 months *versus* 11.6 months, p<0.0001).
Summary/Conclusions: Taken together, our findings disclose a novel environmental circuit co-opted by MM evolution, whereby immunosuppressive HDNs sustain PC cell fitness through arginine depletion to increase p62 and Blimp-1 via the GCN2/CHOP pathway.

E1233

ESTIMATED GLOMERULAR FILTRATION (EGFR) CALCULATED BY CKD-EPI EQUATION COMBINED WITH THE INTERNATIONAL STAGING SYSTEM PROVIDES A POWERFUL PROGNOSTIC MODEL FOR EARLY MORTALITY IN MYELOMA PATIENTS

E. Katodritou[1,*], V. Palaska[1], E. Giannopoulou[1], S. Papadaki[1], A. Gerofotis[1], N. Karampatzakis[1], K. Keramidioti[1], E. Verrou[1], K. Kokoviadou[2], I. Batsis[3], I. Sakellari[3], A. Anagnostopoulos[3], M.-A. Dimopoulos[4], P. Konstantinidou[1], E. Terpos[4]
[1]Hematology Department, Theagenion Cancer Hospital, [2]Hematology Department, Papageorgiou General Hospital, [3]Hematology Department and Bone Marrow Transplantation Unit, G. Papanikolaou General Hospital, THESSALONIKI, [4]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, ATHENS, Greece

Background: During the last decades, the introduction of autologous transplantation and novel agents has improved early mortality rates (EM, henceforth defined as death within one year after diagnosis) in Multiple Myeloma (MM). However, the incidence of EM remains high. Data relating to prognostic factors for EM in MM are limited.
Aims: The aim of this study was to explore for possible prognostic factors for EM, which could be a useful tool for planning treatment strategy in MM.
Methods: We have studied the medical records of 479 patients with MM (M/F: 258/221, median age: 68 years, range 29-88, IgG: 269, IgA: 123, light chain: 72, non-secretory: 15), diagnosed and treated in our Department between January 2001 and January 2016; 86 patients (18%) had EM. Comparisons of patients' characteristics between the EM group and the rest of the patients, were performed with χ^2, one-way ANOVA and Mann Whitney *U* test. Prognostic factors for EM and overall survival (OS) were studied by using logistic regression and cox regression analysis, respectively; OS was plotted by Kaplan-Meier; p<0.05 was considered as statistically significant.
Results: Patients with EM were more often men with a higher median age; hemoglobin, platelets and albumin were lower whereas β2 microglobulin, lactate dehydrogenase (LDH) and calcium were higher in the EM group compared to the rest of MM patients (p<0.05). The percentage of patients with abnormal estimated Glomerular Filtration (eGFR) calculated by chronic kidney disease epidemiology collaboration (CKD-EPI) creatinine equation (<40ml/min/1.73m^2) was higher in EM group compared with the rest of the patients (69% *vs* 17%, *p*<0.001). In accordance with the International Staging System (ISS), advanced MM stage (*i.e.* ISS3) was observed more often in the EM group compared to the rest (65% *vs* 31%, *p*<0.001). High risk cytogenetics including t(4;14), t(14;16) and del17p were present in 48% of patients in the EM group *vs* 21% of the others (p<0.001). The causes of EM included infection/sepsis: 54%, relapsed/refractory disease: 26%, other causes: 6%. Univariate logistic regression analysis demonstrated that ISS, revised ISS (R-ISS), abnormal LDH, hemoglobin <10g/dl, high risk cytogenetics, and CKD-EPI <40ml/min/1.73m^2 were independent prognostic factors for EM. In the multivariate analysis ISS and abnormal eGFR were the only independent prognostic factors for EM. When we incorporated ISS and eGFR in a single prognostic model (CKD-EPI/ISS) we identified 3 distinct prognostic groups: 1) low risk group including patients with ISS1 and CKD-EPI ≥40ml/min/1.73m^2, 2) high risk group including patients with ISS3 and CKD-EPI <40ml/min/1.73m^2 and 3) intermediate risk group including patients that did not fit in either low or high risk group. The incidence of EM in each group was 8.1% 39% and 15.3%, respectively (OR: 2.8, 95% CI:1.9-4.1, *p*<0.001). Multivariate cox regression analysis of prognostic factors for OS in the whole population demonstrated that CKD-EPI/ISS model was the strongest independent prognostic factor for OS (HzR: 0.38, 95% CI: 0.23-0.6, *p*<0.001).
Summary/Conclusions: Based on our data, the combination of eGFR estimated by CKD-EPI with ISS (CKD-EPI/ISS) represents a powerful independent prognostic model for EM and OS, in the era of novel agents. The markers constituting eGFR and ISS are cheap and available for most of MM patients, therefore the CKD-EPI/ISS prognostic model may have a wide application. Nevertheless, the establishment of CKD-EPI/ISS model requires further validation.

E1234

ACTIVATED AND EXPANDED NATURAL KILLER CELLS FROM MULTIPLE MYELOMA PATIENTS DESTROY TUMOR DRUG RESISTANT CELLS AND CLONOGENIC TUMOR CELLS

A. Leivas[1,2,*], I. Rapado[1,2], L. Fernández[1], A. Pérez-Martínez[3], J.J. Lahuerta[2], J. Martínez-López[1,2]
[1]Hematological Malignancies Clinical Research Unit, Spanish National Cancer Research Center, [2]Hematology, Hospital Universitario 12 de Octubre, [3]Pediatrics, Hospital Universitario La Paz, Madrid, Spain

Background: Multiple myeloma (MM) remains an incurable disease. Novel therapeutic strategies targeting drug resistant cells (DRC) and clonogenic tumor cells (CTC) are needed. Our group has conducted a phase I clinical trial with activated and expanded autologous NK cells (NKAEs) in patients with refractory MM with a relevant clinical effect. Likewise, it has been possible to discriminate DRCs in MM by side population (SP) detection.
Aims: The aim of this study was to characterize DRC and to check the activity of NKAEs against these DRCs and CTCs while preserving the hematopoietic progenitor cell.
Methods: Flow cytometry of the side population was performed by Dye Cycle Violet efflux detection to characterize DRC of MM cell lines and bone marrow samples from MM patients. The side population was purified by sorting and characterized by RNAseq. NK cells from MM patients' peripheral blood were obtained and cocultured with the genetically modified K562-mb15-41BBL cells in order to obtain NKAE cells. The activity of NKAE cells against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. I*n vitro* safety against CD34+ progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and cultures of methylcellulose of healthy bone marrow CD34 + progenitors.
Results: SP cells from both cell lines and samples from different stages of MM showed overexpression of stemness markers. Patient NKAE cells were shown to have much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAE cells were able to detect and destroy the SP cells without significant differences. NKAE cells were also able to destroy CTCs from different MM cell lines. Cytotoxicity studies revealed that NKAE cells did not destroy mononuclear cells from healthy bone marrow, even at maximum ratios of 32:1 the mean cytotoxicity was 1.85% (range 0 - 4.47%). Experiments on CD34$^+$ hematopoietic progenitor cell cultures also showed that NKAE cells do not destroy CD34$^+$ clones from healthy bone marrow, confirming the safety of NKAEs.
Summary/Conclusions: SP cells have molecular characteristics of the tumor stem cell compartment in MM. Likewise, NKAE cells from MM patients could

destroy drug resistant MM cells and clonogenic tumor cells with high efficiency, preserving CD34+ hematopoietic cells, and thus constitute an effective and safe therapy against MM.

E1235

UNMASKING THE RETROTRANSPOSON-ORCHESTRATED PRODUCTION OF SOLUBLE RANKL IN MULTIPLE MYELOMA CELLS

S. Papamichos[1,*]
[1]Laboratory of General Biology, Aristotle University of Thessaloniki Medical School, Thessaloniki, Greece

Background: Growing evidence suggest that production of soluble receptor activator of nuclear factor-kappa B ligand (sRANKL) directly by myeloma cells is causally related to generalized bone loss in multiple myeloma (MM). Notably, sRANKL may be produced either by proteolytic cleavage of membrane-bound RANKL or by alternative splicing of *TNFSF11* gene (*TNFSF11* variant 2, sRANKL mRNA). Recent analysis argues against proteolytic processing of the membrane-bound form being the main mechanism of sRANKL production by myeloma cells. Accumulative data indicate that sRANKL mRNA presents a restricted transcriptional pattern, namely is expressed predominantly in malignant cell types. Accordingly, sRANKL mRNA (over)expression in primary MM cells and human MM cell lines has been validated in three independent studies. Furthermore it was recently demonstrated that sRANKL mRNA proximal promoter and first exon are of retroviral origin, residing within a large genomic cluster of transposable elements (TEs).
Aims: To unmask the TE-shaped transcriptional and epigenetic apparatus impelling the expression of sRANKL mRNA in a cell type- and cell context-specific manner.
Methods: RepeatMasker software was used to reveal the presence of integrated TEs in the genomic segment comprising *TNFSF11*. *TNFSF11* RNA-Seq data, generated by the GTEx project across 51 normal human tissues, were analyzed via GTEx Portal. *TNFSF11* RNA-seq data from 4 bone marrow samples and 8 white blood cells samples, generated from the PRJEB4337 and PRJNA182351 BioProjects, were analyzed via the NCBI portal. *TNFSF11* transcription factor (TF) ChIP-seq data were downloaded from the UCSC Genome Browser Database. Data on *TNFSF11* proximal promoter methylation status in 63 cell lines were downloaded from the HAIB Methyl450 ENCODE track.
Results: RNA-Seq data from 51 normal human tissues show that sRANKL mRNA is expressed exclusively in testis, which is in accordance with the retroviral origin of the transcript. Data analysis from the PRJEB4337 and PRJNA182351 BioProjects further validates the null expression of sRANKL mRNA in normal human bone marrow and white blood cells. Methylation status of sRANKL mRNA promoter in 5 lymphoblastoid cell lines (LCLs) signifies that the retroviral promoter remains heavily methylated in these cell types. *TNFSF11* TF ChIP-seq data show that 5 of 161 TFs can bind to the TE-derived sRANKL mRNA promoter region. Four of the five TFs (EBF1, PAX5, IKZF1, and PU.1) bind to this genomic segment exclusively in LCLs, signifying a cell-type specific transcriptional regulation. Notably, all 4 TFs are known to play a major role in normal and/or malignant lymphopoiesis. Furthermore, IKZF1 and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.
Summary/Conclusions: Transcription of sRANKL mRNA is driven by a retroviral promoter which remains heavily methylated, thereby inactive, in normal lymphocytes. Epigenetic derepression of this promoter during the course of myelomatogenesis resulting in the (over)expression of sRANKL mRNA by myeloma cells represents a plausible scenario. Should the IKZF1 and the PU.1 TFs act as enhancers of sRANKL mRNA expression, directly contributing to upregulation of sRANKL production in MM, is a tantalizing hypothesis that warrants further investigation especially because this type of transcriptional boost could be intercepted following treatment with IMiDs. That Lenalidomide treatment downregulates the amount of sRANKL in the serum of patients with MM through inhibiting PU.1 expression (Breitkreutz *et al*., Leukemia 2008) is in accordance with the above and further raises the interest on the mechanisms promoting the anti-osteoclastogenic properties of IMiDs.

E1236

THE RATIO OF PATHOLOGICAL PLASMOCYTES, ASSESSED BY 8-COLOR FLOW CYTOMETRY, PREDICTS OF RISK OF EVOLUTION IN MONOCLONAL GAMMOPATHY OF UNKNOWN SIGNIFICANCE AND SMOULDERING MULTIPLE MYELOMA

C. Brouzes[1,*], L. Lhermitte[1], C. Zaratzian[1], M.O. Chandesris[2], L. Frenzel[2], R. Delarue[2], F. Suarez[2], O. Hermine[2], E. Macintyre[1], V. Asnafi[1]
[1]Laboratory Onco Hematology, [2]Clinical Hematology, Necker Enfants Malades Hospital and Descartes University, Paris, France

Background:mgUS and SM are defined by the presence of a monoclonal immunoglobulin and bone marrow infiltration by plasmocytes, with no associated symptoms of Multiple Myeloma (MM). The risk of development of symptomatic MM justifies identification of the factors associated with an increased risk of evolution. Flow cytometric quantification of the ratio of bone marrow pathological/total plasmocytes (PP/PT) has been reported to be predictive in this context (Pérez-Persona E. *et al.* Blood 2007; 110: 2586–2592).
Aims: We undertook to test this in a single center study.
Methods: All patients undergoing bone marrow evaluation following identification of a monoclonal peak (at diagnosis or during follow-up) during a 7.5year period with a diagnosis ofmgUS (n=154) ou SMM (n=56) and at least 6 months follow-up were analysed by 8-color FC (including 11 antibodies) from fresh whole bone marrow. PP/PT ratios ≥95% were considered high risk. Disease evolution was indicated by a necessity to treat.
Results: The 210_PP/PT ratios were on average 77% (10-100). Amongst the 154mgUS patients, 24 had a ratio >95%, of which 8 (33%) evolved, compared to 9/130 (7%) with a ratio below 95%. Only 2 of these 8mgUS demonstrated other high risk factors (a non-IgG monoclonal peak or a peak at >15g/L). Amongst SMM patients, 22/30 (73%) patients with a high ratio evolved, of which 9 (41%) had a non-IgG peak, compared to 10/26 (38%) evolution in SMM with low PP/PT ratios. The risk of evolution to active MM was significantly higher in patients with a PP/PT ≥ 95%, both in themgUS (p<0.0001) and in the overallmgUS + SMM group (p<0.0001). The delay to treatment start was significantly longer in the PP/PT <95% group, in both themgUS (p<0.0001) and overall (p=0,0004) groups. There was a discordance between PP/PT ratio and disease evolution in 11% (17/154)mgUS patients and 23% (48/210) of the overall group but no other FC markers associated with an increased risk of evolution could be identified.
Summary/Conclusions: We confirm the clinical value of a simple, rapid, two-tubes FC quantification of the proportion of pathological plasma cells in the evaluation of the risk and kinetics of disease evolution inmgUS and SMM. It's use allows identification of patients which require more frequent follow-up.

E1237

ADENOSINE IN THE MYELOMA BONE MARROW NICHE: IMMUNE CHECKPOINT AND KEY PLAYER IN DISEASE PROGRESSION

A. Horenstein[1,2,*], A. Chillemi[1], V. Quarona[1], F. Costa[3], D. Toscani[3], F. Morandi[4], D. Marimpietro[4], N. Giuliani[3], F. Malavasi[1,2]
[1]Medical Sciences, University of Turin, [2]CERMS, A.O.U. Citta della Salute e della Scienza, Turin, [3]Myeloma Unit, Department of Clinical and Experimental Medicine, University of Parma, Parma, [4]Laboratory of Oncology, Istituto Giannina Gaslini, Genova, Italy

Background: The tumor microenvironment is rich in extracellular mono- and di-nucleotides (ATP, NAD) which are metabolized by cell surface ectoenzymes to produce adenosine (Ado), a nucleoside involved in the control of inflammation and immune responses. Multiple myeloma (MM), a plasma cell malignancy that develops within the bone marrow (BM) niche, overexpresses CD38, a molecule with complex functions. As a nucleotide-metabolizing ectoenzyme, CD38 catalyzes the initial disassembly of NAD (to cADPR and ADPR), which is followed by adenosinergic activity, provided that CD38 is operating in the presence of other ectoenzymes (CD203a and CD73).
Aims: To demonstrate that adenosinergic pathways contribute to customize homeostasis in MM.
Methods: Evaluation of the expression of adenosinergic ectoenzymes was assessed by immunohistochemical and flow cytometric analysis on cell lines, and primary myeloma cells and BM biopsies from patients with MM or with asymptomatic monoclonal gammopathies (MGUS and SMM). Having investigated the cell antigenic pattern, the adenosinergic functionality of BM cell populations and of microvesicles (MVs) isolated thereof was analyzed by HPLC to evaluate Ado production.
Results: Using BM plasma aspirates, we showed that NAD within the MM niche is able to activate a discontinuous (*i.e.*, multicellular) pathway for Ado production that relies upon CD38, CD203a and CD73 (or TRAP) ectonucleotidases, depending on the environmental pH. Ado production was likely due to interactions taking place between myeloma and other cells lining the BM niche. The results of a pilot study revealed a parallel between Ado levels and disease progression, and patients with symptomatic MM usually have higher levels of Ado. This is reflected statistically in the International Staging System (ISS) for MM. Preliminary studies showed that MVs deriving from MM patients are peculiar in that i) they are enriched for CD38, CD203a and CD73 ectoenzymes and ii) are able to generate Ado. These MVs may adhere or fuse with neighboring cells, egress the BM niche and eventually reach the bloodstream. Thus, one aspect of the dynamics of available anti-CD38 antibodies for MM therapy is the role of polarization and release of the MVs after treatment. *In vitro* studies showed that MV/IgG antibody complexes can be captured by Fc receptor-expressing cells.
Summary/Conclusions: 1) We hypothesize that MM cells deploy the adenosinergic metabolic strategy to silence immune effectors during the progression of MM from indolent monoclonal gammopathy to symptomatic overt disease; 2) While these observations may only be correlative and a reflection of the tumor burden, Ado levels in the BM plasma may prove to be a useful marker of myeloma progression; 3) The therapeutic IgG on the surface of adenosinergic MVs may acts as a link determining the final destination of MVs.

E1238

TREATMENT OPTIMIZATION FOR MULTIPLE MYELOMA: SCHEDULE-DEPENDENT SYNERGISTIC CYTOTOXICITY OF POMALIDOMIDE AND CARFILZOMIB ON AN IN VITRO AND EX-VIVO MODEL

E. Borsi[1,*], M. Martello[2], B. Santacroce[2], V. Solli[2], R. Termini[2], E. Zamagni[2], P. Tacchetti[2], L. Pantani[2], S. Rocchi[2], M. Cavo[2], C. Terragna[2]
[1]Fondazione Umberto Veronesi (FUV), Milano, [2]Department of Experimental Diagnostic and Specialty Medicine - DIMES, Institute of Hematology "L. e A. Seràgnoli" - University of Bologna, Bologna, Italy

Background: In recent years significant progress has been made in the understanding of Multiple Myeloma (MM) biology. These advances have translated into the development of new drugs and a different approach to treatment, which has ultimately translated into an unprecedented rate of complete remissions. Immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) form the backbone of modern MM treatment,but new and more targeted treatments are under development and are being tested in the context of clinical trials.Pomalidomide (POM) is a third-generation IMiD with immunomodulatory, antiangiogenic, and direct anti-MM activities, and greater *in vivo* potency than its sister Lenalidomide. Carfilzomib (CAR) is a second generation irreversible PI that is structurally and mechanistically distinct from Bortezomib. Preclinical study suggested that the timing and dosing schedules of IMiDs in combination with PIs treatment is critical, proposing a first evidence that established treatment regiments need to be carefully re-evaluated to maximize the anti-tumor effects.
Aims: In this study we tried to optimize the anti-MM therapy using the new class of agents of IMiDs and new generation PIs, by evaluating a possible synergistic effect between POM and CAR.
Methods: For the purpose of this study we used five *bona fide* MM cell lines (MM1.S, OPM-2, NCI-H929, KMS12.BM and U266), a human bone marrow stromal (BMS) cell line (HS-5 cells) and primary samples from newly diagnosed MM patients. Apoptosis analysis was done up to 48h after administration of the first drug. For each drug, three different concentrations were used: low dose, intermediate dose and high dose. Since the BM microenvironment is a complex and active system, with potential contributions of both physical adhesion and soluble factors, we used three experimental conditions to differentiate these interactions: 1) MM cells cultured in complete medium, 2) MM cells suspended in medium conditioned in the prior presence of BMSCs, or 3) MM cells co-cultured with BMSCs in a transwell system.
Results: Using the median effect method of Chou Talalay, we evaluated the combination indices for simultaneous and sequential treatment schedules, and we found that the schedule of administration is important to maximize the synergistic effects. Indeed, schedule-dependent synergistic cytotoxicity was demonstrated for the combination of IMiDs and PIs and a maximal apoptosis consistently observed in IMiDs pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models. Our data overall suggest that the administration of IMiDs before PIs can improve efficacy. Clinical trials are needed to investigate the most effective schedule, which could be to start the administration of IMiDs a day before PIs to increase cells killing.
Summary/Conclusions: Schedule-dependent synergistic cytotoxicity was demonstrated for the combination of CAR and POM and a maximal apoptosis consistently observed in POM pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models using low dosage of both drugs. Whilst the clinical efficacy of CAR and POM combinations has been demonstrated, the synergistic cytotoxicity may be further exploited by using optimized schedule. Utilizing such a schedule with IMiDs pre-treatment may improve the depth and duration of response of MM patients both as upfront therapy and in the relapsed/refractory setting.

ASSESSMENT OF THE IMPACT OF POST-AUTOLOGOUS STEM CELL TRANSPLANT MAINTENANCE THERAPY ON SURVIVAL OUTCOMES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE COMMUNITY-BASED CONNECT MM REGISTRY

S. Jagannath[1,*], R. Abonour[2], B.G. Durie[3], J.J. Shah[4], M. Narang[5], H.R. Terebelo[6], C.J. Gasparetto[7], K. Toomey[8], J.W. Hardin[9], L. Wagner[10], A. Agarwal[11], S. Srinivasan[11], A. Kitali[11], F. Zafar[11], M. Sturniolo[11], R.M. Rifkin[12]
[1]Mount Sinai Hospital, New York, [2]Indiana University Simon Cancer Center, Indianapolis, [3]Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, [4]MD Anderson Cancer Center, Houston, [5]US Oncology Research, Maryland Oncology Hematology, Columbia, [6]Providence Cancer Institute, Southfield, [7]Duke University Medical Center, Durham, [8]Steeplechase Cancer Center, Somerville, [9]University of South Carolina, Columbia, [10]Wake Forest University School of Medicine, Winston-Salem, [11]Celgene Corporation, Summit, [12]US Oncology Research, Rocky Mountain Cancer Centers, Denver, United States

Background: Randomized phase 3 clinical trials have shown that maintenance therapy after autologous stem cell transplant (ASCT) can extend time to progression, progression-free survival (PFS) and overall survival (OS) for patients (pts) with newly diagnosed multiple myeloma (NDMM) (Sonneveld, *J Clin Oncol,* 2012; McCarthy, *N Engl J Med,* 2012; Attal, *N Engl J Med,* 2012; Palumbo, *N Engl J Med,* 2014; Attal, ASCO, 2016). Connect MM is a largely community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns and outcomes in pts with NDMM in clinical practice.
Aims: The Connect MM registry was used to assess impact of maintenance therapy on survival outcomes in pts with NDMM receiving ASCT.
Methods: Adult pts with NDMM were eligible to enroll in the registry within 60 days of diagnosis. Pts were enrolled in 2 sequential cohorts and were treated at the clinician's discretion as per standard of care. Cohort 1 pts receiving induction and ASCT were included in the analysis and characterized into 4 maintenance regimen subgroups: no maintenance, lenalidomide (LEN)-based maintenance, bortezomib (BORT)-based maintenance, and LEN+BORT maintenance. Duration was from 100 days post-ASCT (no maintenance group) or start of maintenance until progressive disease, death, discontinuation, or data cutoff of January 7, 2016. End points were PFS, second PFS, OS, and safety. An exploratory analysis of the impact of baseline characteristics on survival outcomes was performed.

Table 1.

	LEN Maintenance (n = 213)	No Maintenance (n = 165)	Hazard Ratio (95% CI)
Median PFS, months	50.3	30.8	0.62 (0.46, 0.82) *P* = .0009
3-yr PFS	56%	42%	
Median OS, months	not reached	not reached	0.54 (0.36, 0.83) *P* = .0050
3-yr OS	85%	70%	

Results: A total of 1493 pts were enrolled in Cohort 1 from Sep 2009 to Dec 2011; 1450 were treated, 81% (n=1173) in a community setting. Of those, 432 (29%) met analysis criteria. Median follow-up was 39.3 months. Median age was 60 y (range, 24-78); 60% were men; and 86% were white. A total of 165 pts did not receive maintenance. Of 267 pts receiving maintenance, 213 (80%) received LEN-based maintenance; 30 (11%) received BORT-based maintenance; and 16 (6%) received LEN+BORT maintenance. Of the maintenance groups, only data from LEN maintenance is presented; small sample sizes in the other maintenance groups limited interpretation. The median treatment duration was 35.2 months for pts who received LEN maintenance and 26.1 months for those who did not receive maintenance. Median PFS was significantly longer for pts who received LEN maintenance *vs* no maintenance (50.3 months *vs* 30.8 months; hazard ratio [HR]=0.62 [95% CI: 0.46, 0.82); *P*=.0009; Table). OS was also significantly improved for pts who received LEN maintenance *vs* no maintenance (HR=0.54 [95% CI: 0.36, 0.83]; *P*=.0050). Second PFS (PFS for second-line treatment) was similar for both LEN and no maintenance groups. Exploratory analyses showed generally similar PFS and OS improvements across subgroups (age, ECOG status, International Staging System stage, risk group, and induction regimen). No new safety signals were observed.
Summary/Conclusions: In this observational study, post-ASCT LEN maintenance therapy significantly improved PFS and OS compared to no maintenance. These improvements appeared to be independent of induction regimen. Preliminary analysis of second PFS suggests no adverse impact of maintenance treatment on the efficacy of second-line therapy. These data, from a largely community-based setting, support results from randomized phase 3 trials.

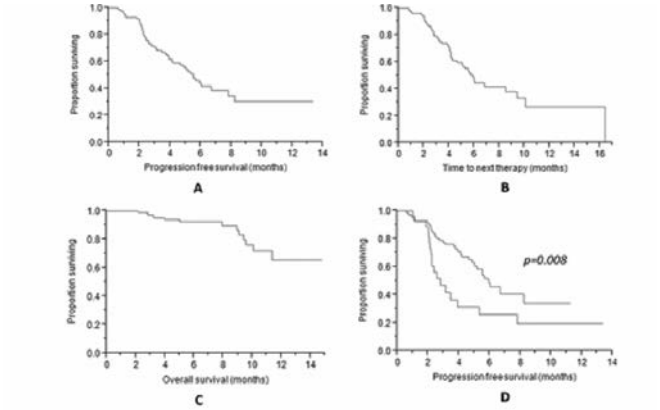
DARATUMUMAB-BASED COMBINATION THERAPIES IN HEAVILY-PRE-TREATED PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA

A. Lakshman[1], J. Abeykoon[2], S. Kumar[1], V. Rajkumar[1], T. Kourelis[1], F. Buadi[1], D. Dingli[1], L. Martha[1], W. Gonsalves[1], A. Dispenzieri[1], R. Kyle[1], Y. Lin[1], R. Go[1], R. Warsame[1], M. Hobbs[1], A. Fonder[1], Y. Hwa[1], S. Hayman[1], S. Russell[1], N. Leung[1], M. Gertz[1], P. Kapoor[1,*]
[1]Division of Hematology, [2]Internal Medicine, Mayo Clinic, Rochester, United States

Background: Daratumumab-based Combination Therapies (DCT) with bortezomib (V)/ lenalidomide (R)/ pomalidomide (P) and dexamethasone (d) have shown exceptional activity in relapsed and/or refractory multiple myeloma (RRMM) in trials. Experience outside of trials since the approval of Daratumumab (D) in 2015 is limited.
Aims: We aimed to review the outcomes of patients who received DCT at our institution.
Methods: Records of RRMM patients seen at Mayo Clinic, MN from December 2015 –December 2016 were reviewed. Patients who received ≥ 1cycle of DCT were included. Time-to-event analyses were done from date of starting DCT using Kaplan Meier method. Common terminology criteria for adverse events v4.0 were used to grade toxicities.
Results: Of 130 patients, 59% were males and median age at DCT initiation was 67 (43-93) years, ECOG performance score was ≥2 in 29%. Patients were classified as mSMART high (22%), intermediate (22%) or standard (56%) risk. Median time from diagnosis to initiation of DCT was 51.3 (5-156) months, and median number of prior therapies was 4 (1-14). Eighteen (14%) of patients were refractory to prior daratumumab monotherapy. Fifty-three (41%), 34 (26%) and 25 (19%) received DPd, DRd and DVd respectively. Eighteen (14%) patients received 'other' DCT. Median time to first response (≥ PR) was 3.1 months (95% CI 2.1-4.6). Overall response rate was 46%, [complete remission-2%, very good partial remission-18%, partial remission-26%]. Minimal response was seen in 17%, with clinical benefit rate of 62%. Median estimated follow up from initiation of DCT was 5.5 months (CI 4.2-6.1). The median duration of response was 6.1 months [CI 5.1- not reached (NR)]. Median progression free survival (PFS) was 5.5 months (CI 4.1-7.8) (figure A) and median time to next therapy (TTNT) was 5.9 months (CI 4.6-9.4) (figure B). Median PFS for DPd, DRd, DVd and other DCTs were 4.6 (CI 2.7-NR), 7.8 (CI 5-NR), 3.9 (CI 2.1-NR) and 3.9 (CI 2.8-8.2) months, respectively (p=0.3). Median overall survival (OS) from starting DCT was NR (CI 11.4-NR) (figure C). Median PFS for quadruple refractory (n=28) MM was 2.8 months (CI 2.2-5.3) *vs* 5.9 months (CI 4.9-NR) for the rest (p=0.008) (figure D). Grade 3 or higher hematological toxicities were seen in 42% of patients. Other toxicities included infections (37%), fatigue (31%), infusion reactions (16%) and diarrhea (10%).



Panel showing Kaplan Meier curves for (A) progression free survival, (B) time to next therapy and (C) overall survival for the entire cohort of relapsed/refractory multiple myeloma (RRMM) patients who received daratumumab-based combination therapies and (D) the difference in progression free survival between quadruple refractory (blue curve) RRMM patients and the rest (red curve).

Figure 1.

Summary/Conclusions: DCT are effective in RRMM, but the PFS remains short, particularly in quadruple refractory patients, reflecting the challenges encountered in managing heavily-pretreated, and often less fit patients, in routine practice.

E1241

IMPACT OF METFORMIN USE IN THE OUTCOMES OF MULTIPLE MYELOMA PATIENTS POST STEM CELL TRANSPLANT

N. Duma[1,*], J. Vera-Aguilera[1], J. Paludo[1], Y. Wang[1], T. Anagnostou[1], A. Fonder[1], F. Buadi[1], S. Kumar[1], M. Lacy[1], S. Hayman[1], A. Dispenzieri [1], M. Gertz[1], D. Dingli[1]
[1]Hematology, Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM), a monoclonal plasma cell disorder, is one of the most common hematologic malignancies in the US. In preclinical studies, metformin demonstrated plasma cells cytotoxicity. However there is lack of studies translating the effect of metformin into the clinical setting.
Aims: Assess the clinical effect of metformin in patients with MM.
Methods: All MM patients who underwent stem cell transplant (SCT) at the Mayo Clinic Rochester from 2007 to 2012 were reviewed. Patients were grouped based on metformin use. Initial diagnosis at our institution and ≥12 months of follow up were required. Kaplan-Meier method and Cox regression were used for time-to-event and multivariate analysis.
Results: Out of 687 patients, 78 (11.4%) patients were using metformin at the time of MM diagnosis. Baseline characteristics in the metformin and no-metformin groups were similar. Median metformin dose was 2000mg daily and median duration of metformin use from MM diagnosis was 22 months. Patients on the Metformin group achieved higher rates of complete response after SCT (41% *vs* 29% p<0.02). Median progression-free survival (PFS) after SCT was longer in the Metformin group, 31.3 months (95% CI: 10.4-52.2) *vs* 16.6 months in the no-metformin group (95%CI: 14.5-18.7) p<0.04. There was a trend toward longer overall survival in the Metformin group, but it was not statistically significant (170 *vs* 106 months, p<0.10). In a multivariate analysis of metformin use, age, sex, international staging system (ISS), LDH and cytogenetics/FISH, the former was an independent predictor of PFS after SCT (OR: 0.38, 95%CI: 0.20-0.68, p<0.001).

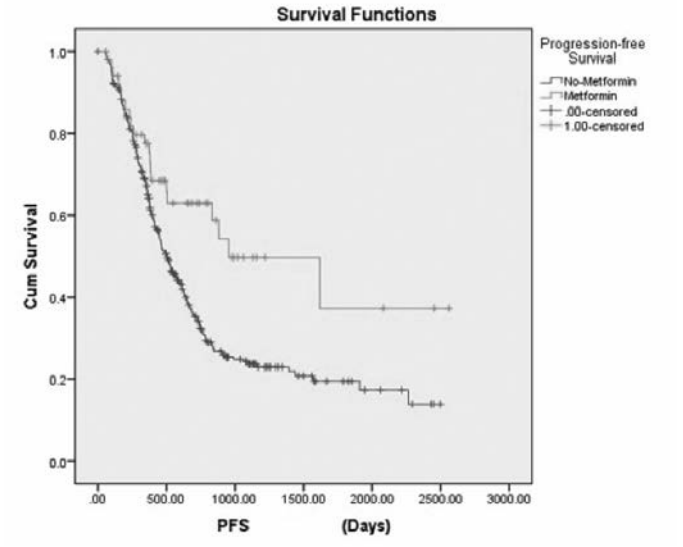


Figure 1.

Summary/Conclusions: Metformin use was associated with a better progression-free survival and higher complete response rates after SCT in our MM cohort. A trend toward better overall survival was also noted in the Metformin group. Larger studies are needed to enhance our understanding of the clinic effect of metformin on MM.

E1242

COMPARING WHOLE BODY MRI WITH PET-CT IMAGING AT DIAGNOSIS OF MYELOMA

J. Vidler[1,*], G. Havariyoun[2], G. Vivian[3], I. Walker[1], M. Streetly[1], K. Cuthill[1], R. Benjamin[1], N. Mulholland[3]
[1]Department of Haematological Medicine, [2]Department of Medical Engineering and Physics, [3]Departments of Radiology and Nuclear Medicine, King's College Hospital, London, United Kingdom

Background: Imaging in the diagnosis of myeloma is a rapidly developing field. First line imaging has traditionally been a skeletal survey with plain films, however new guidelines recommend whole body imaging to aid the diagnosis of plasma cell disorders. The International Myeloma Working Group recommend low-dose whole body computerised tomography (LDWBCT), PET-CT or whole body magnetic resonance imaging (WBMRI) as initial imaging modalities.
Aims: To compare WBMRI with PET-CT as initial imaging modalities at diagnosis of myeloma or plasmacytoma.
Methods: Both WBMRI and PET-CT were performed at diagnosis of myeloma or a plasmacytoma in 33 patients presenting to King's College Hospital, London. The scans were reviewed independently by two Consultants in Radiology

and Nuclear Medicine, looking for focal bone lesions, bone marrow pattern and incidental findings. Details of the patients' demographics, myeloma diagnosis and treatment were collected from the medical records.
Results: Of the 33 patients, 24 were male. The median age was 64 years(range=43-86 years). One patient had a solitary plasmacytoma, the other 32 had myeloma (21 IgG, 3 IgA, 2 non-secretory, 4 light chain disease, 2 biclonal myeloma). Most had ISS stage I disease with a median paraprotein at diagnosis of 17 (range 0-52.6). 21 patients had a bone marrow plasma cell burden of 10-60%, 10 patients >60% and 2 were unknown. Sixteen patients were diagnosed with smouldering myeloma and a 'watch and wait' policy was adopted. Eleven patients were treated with chemotherapy, 4 were entered into a clinical trial, one was offered palliative care and one was referred to our centre for autograft. WBMRI identified a focal lesion of disease in 30% of patients compared with 36% by PET-CT. This was not a statistically significant difference (p=0.18). In addition there was no statistically significant difference between PET-CT & MRI in detecting <3 or >3 lesions (p=0.705 and p=0.083 respectively). The apparent diffusion coefficient (ADC) at vertebrae L5 (using diffusion weighted MR imaging) was measured. This showed a strong correlation with the degree of bone marrow infiltration by plasma cells (r=0.64). An ADC of <600mm^2/s had a negative predictive value of 93% for a bone marrow plasma cell infiltrate of >60%. There was also a significant difference (p=0.012) in the ADC between those with smoldering myeloma and those with symptomatic disease. It was noted that 9 scans resulted in incidental findings including pneumonia, adrenal lesions and one case of colorectal cancer.
Summary/Conclusions: We have shown no difference in PET-CT and WBMRI in detecting a myeloma defining focal bone lesion, or providing prognostic estimate of burden of disease. Using MRI, a measure of the ADC at vertebrae L5 has been shown to be a semi-quantitative parameter that correlates with bone marrow plasma cell infiltration and distinguished between those with smouldering and symptomatic disease. In addition it is noted that whole body imaging has led to incidental findings of further pathology, including an unrelated malignancy, which may lead to useful clinical information or to further investigations and imaging which may not be needed.

E1243

PERSISTENCE OF MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY CAN HINDER RECOVERY OF ORGAN DAMAGE IN PATIENTS WITH AL AMYLOIDOSIS

P. Milani[1,*], M. Massa[1], M. Basset[1], F. Russo[1], P. Berti[2], A. Foli[1], O. Annibali[2], G. Palladini[1], G. Merlini[1]
[1]Department of Molecular Medicine, Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, [2]Hematology, Stem Cell Transplantation, Transfusion Medicine and Cellular Therapy, Research Unit, Università Campus Bio-Medico di Roma, Rome, Italy

Background: In multiple myeloma, Minimal Residual Disease (MRD) demonstrated by multiparameter flow cytometry (MFC) identifies subjects with significantly shorter survival among those who attain complete response (CR). The role of MRD in AL amyloidosis has not been assessed so far.
Aims: In the present study, we assessed the MRD by MFC in patients with AL amyloidosis who attained CR.
Methods: CR was defined as per current criteria (negative serum and urine immunofixation and normal free light chain ratio). For flow cytometry studies bone marrow samples were processed following the Euro Flow Bulk Lysis Standard Operating Protocol and stained with the EuroFlowIMF MM MRD panel. At least 5x10^6 events were measured using a FACSCanto II (USA) instrument. Data were analyzed using the Infinicyt software (Spain). Patients were identified as having residual disease if a discreet population of clonal plasma cells comprising ≥50 events was identified (10^{-5} limit of detection).
Results: Twenty-eight patients were tested (7 were found to have relapsed at the time of MRD assessment with monoclonal components detectable and MRD+) and 21 satisfied current criteria for CR. Nineteen (90%) had renal and 9 (44%) had cardiac involvement at diagnosis. More than 2 lines of therapy were required to achieve CR in 7 subjects. Median time to CR was 10 months (range: 3-82). Five patients (62%) had achieved cardiac response and 9 (50%) renal response at the time of CR. The median time from CR to MRD was 30 months (range: 6-148), this was not different in the MRD positive *vs* negative patients. Flow cytometry identified MRD in 9 patients (43%). A median of 1089 (range 256-2500) corresponding to 0.04% (range 0.02-0.3%) plasma cells with abnormal phenotype were detected in patients MRD+. No differences in organ involvement, cardiac and renal stage, type of therapy, number of treatments, and organ response at the time of CR was found between the two groups. However, a further improvement of cardiac function compared to the time of CR was observed in all 5 evaluable MRD- patients and in none of the 2 MRD+ patients (P=0.047). Compared to the time of CR, renal response was obtained in 7 MRD- subjects (84%) and in 4 (50%) MRD+ (P=0.153). Overall, further improvement of cardiac or renal function after CR was significantly associated with absence of MRD (P=0.012).
Summary/Conclusions: This proof-of-concept study indicates that 43% of patients with AL satisfying current criteria for CR have detectable MRD. MRD positivity could in part explain persistence of organ damage is patients in CR. A validation study in a larger cohort is ongoing. The possible impact of MRD should be considered in trials aiming at increasing organ response rate in patients in CR.

E1244

RATES OF PERIPHERAL NEUROPATHY (PN) IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH CARFILZOMIB *VS* COMPARATORS IN PIVOTAL PHASE 3 TRIALS

R. Niesvizky[1,*], V. Hungria[2], P.J. Ho[3], A. Suvorov[4], D. White[5], D. Ben-Yehuda[6], L. Zhou[7], K. Iskander[7], L. Rosiñol[8]
[1]Center for Myeloma, New York Presbyterian Hospital Weill Cornell Medical Center, New York, United States, [2]Santa Casa de São Paulo Medical School, São Paulo, Brazil, [3]Institute of Haematology, Royal Prince Alfred Hospital, Camperdown, Australia, [4]Hematology Department, First Republican Clinical Hospital of Udmurt Republic, Izhevsk, Russian Federation, [5]Dalhousie University and QEII Health Sciences Centre, Halifax, Canada, [6]Kiryat Hadassah, Jerusalem, Israel, [7]Amgen Inc., Thousand Oaks, United States, [8]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Hospital Clinic, Barcelona, Spain

Background: PN is a dose□limiting toxicity for some anti myeloma agents, such as the proteasome inhibitor bortezomib (V).
Aims: Carfilzomib (K), a novel irreversible proteasome inhibitor associated with a low incidence of PN, was evaluated in two recent phase 3 studies in RRMM patients.
Methods: This analysis evaluated PN rates in ASPIRE (K [27mg/m^2] lenalidomide [R]-dexamethasone[d] [KRd] *vs* Rd in relapsed or refractory MM; Stewart 2015) and ENDEAVOR (Kd [K 56mg/m^2] *vs* Vd in RRMM; Dimopoulos 2016). We evaluated treatment emergent grade ≥2 PN, patient reported outcomes (PROs; QLQ C30 pain, FACT/GOG neurotoxicity subscales), and progression free survival (PFS) in patients with a baseline history of PN (patients with grade ≥3 PN at baseline or grade 2 PN with pain at baseline were excluded from the studies).
Results: In ASPIRE, grade ≥2 PN rate was low (8.9% [KRd] *vs* 8.0% [Rd]; Table). Pain subscale scores were similar between arms. Median PFS was longer with KRd *vs* Rd for patients with grade 2 PN at baseline. In ENDEAVOR, grade ≥2 PN rate during the study (prespecified key secondary endpoint) was significantly lower with Kd *vs* Vd (6.0% *vs* 32.0%; Table). Patients had significantly improved pain and neurotoxicity subscale scores with Kd *vs* Vd. PFS improved with Kd *vs* Vd in patients with baseline history of grade 2 PN (Table 1).

Table 1.

	ASPIRE		ENDEAVOR	
	KRd	Rd	Kd	Vd
Grade ≥2 PN during study, safety population, %	8.9	8.0	6.0	32.0
OR (95% CI)	1.132 (0.683, 1.876) p=0.6850		0.137 (0.089, 0.210) p<0.0001	
PRO, LS mean difference				
Pain: QLQ–C30 subscale, ITT (95% CI)	−1.02 (−3.77, 1.73) p=0.47		−2.35 (−4.30, −0.39) p=0.0186	
Neurotoxicity: FACT/GOG–NTx subscale, safety population (95% CI)	–		0.84 (0.40, 1.28) p=0.0002	
PFS by baseline history of PN, ITT				
Yes, n	144	137	215	244
Median (95% CI), mo	23.2 (18.0, 25.9)	17.6 (13.9, 26.0)	18.7 (13.88, NE)	9.4 (7.53, 10.39)
HR (95% CI)	0.947 (0.692, 1.296)		0.54 (0.410, 0.715)	
Grade 2, n	22	24	71	81
Median (95% CI), mo	24.2 (19.6, NE)	14.8 (7.4, NE)	18.6 (10.20, NE)	5.6 (4.47, 7.40)
HR (95% CI)	0.695 (0.321, 1.507)		0.42 (0.266, 0.677)	

Summary/Conclusions: In ENDEAVOR, the rate of PN was significantly lower with Kd then with Vd; in ASPIRE, PN rate was similar for KRd and Rd. Improved pain and neurotoxicity subscale scores with K may be attributed to better disease control and/or lower PN rates.

E1245

EARLY RELAPSE FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANT IN MYELOMA IS A POOR PROGNOSTIC MARKER FOR OVERALL SURVIVAL AND IS DIFFICULT TO PREDICT AT DIAGNOSIS OR DURING INDUCTION TREATMENT

I. Walker[1,*], A. Coady[2], I. El-Najjar [3], K. Wilson[4], K. Cuthill[1,3], W. Ingram[4], M. Kazmi[3], K. Raj[1], R. Benjamin[1], S. Schey[1], A. Pagliuca[1], G. Mufti[1], M. Streetly[1,3], C. Bygrave[4]
[1]Department of Haematology, King's College Hospital Foundation Trust, [2]Guy's, King's and St Thomas' School of Medical Education, King's College London, [3]Department of Haematology, Guy's and St Thomas' NHS foundation Trust, London, [4]Department of Haematology, University Hospital Wales, Cardiff, United Kingdom

Background: High dose chemotherapy followed by autologous stem cell transplant (ASCT) remains the gold standard treatment in myeloma for young

patients at induction. A number of factors have been shown to correlate with overall survival (OS) and progression free survival (PFS) including depth of remission prior to ASCT, Initial ISS stage and high risk cytogenetics. Emerging evidence has demonstrated that early relapse following ASCT is associated with reduced OS, and is not correlated with depth of pre-transplant response.
Aims: To characterise myeloma patients who relapsed within 12 months of ASCT, through baseline characteristics and transplant engraftment, and assess the impact of this early relapse on OS and PFS.
Methods: We performed a multicentre retrospective analysis of patients who underwent ASCT at 3 centres between 01/2009 – 02/20016 (London) and 06/2006 – 03/2013 (Cardiff). Baseline characteristics were reviewed and ASCT engraftment was assessed by; time to neutrophils 50 x 10^9/l and platelets >20 x 10^9/l. Post-transplant PFS & OS was calculated by time (months) from diagnosis to progression or death.
Results: 443 myeloma patients were identified, median age was 57 (r 31-73), 56% were male. 41% of patients were ISS stage 1, 34% stage 2, 25% stage 3. Cytogenetic data was available for 139 patients. 1st-line therapy prior to transplant was immunomodulatory drug (IMiD) based (THAL/LEN) for 318/443 patients & 72/443 were proteasome inhibitor (PI) based (BORT/CARF). In addition, 11 patients received combination PI and IMiD. Median time from start of therapy to ASCT was 10 months (r 3-109m). 67 patients progressed within 12m of ASCT (early progression). No statistical difference was found between <12m or >12m relapse for: age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetics, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS from diagnosis: 31 months (95% CI 21- 39) compared to non-progressive patients (median OS:103m 95% CI 89-117) p<0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) *vs* progression >12 months median OS:89 months (95%CI 79-98m) p<0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical difference between patients who received PIs, IMiDs or both 1st line (p=0.484). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x10^9/l was associated with reduced OS from ASCT for each centre HR 1.14 & 1.20 (p= 0.046 & 0.03) for Cardiff or London centres respectively (Cox's Method).
Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient stromal factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCTs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in this extremely poor prognosis group.

PATIENT-REPORTED OUTCOMES (PROS) WITH IBRUTINIB: SUBSTUDY OF INNOVATETM FOR WALDENSTRÖM MACROGLOBULINEMIA (WM)

J. Trotman[1,*], M.A. Dimopoulos[2], A. Tedeschi[3], J.V. Matous[4], L.T. Heffner[5], C. Shustik[6], R. García-Sanz[7], J.J. Castillo[8], V. Leblond[9], E. Kastritis[2], J. Li[10], T. Graef[10], E. Bilotti[10], C. Buske[11]
[1]Haematology, Concord Repatriation General Hospital, Concord, Australia, [2]National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, [3]Azienda Ospedale Niguarda Ca' Granda Hospital, Milan, Italy, [4]Colorado Blood Cancer Institute, Denver, [5]Winship Cancer Institute of Emory University, Atlanta, United States, [6]Royal Victoria Hospital at McGill University Health Centre, Montreal, Canada, [7]Hospital Universitario de Salamanca, Salamanca, Spain, [8]Dana-Farber Cancer Institute, Boston, United States, [9]Hôpital Pitié-Salpêtrière APHP, UPMC Université, Paris, France, [10]Pharmacyclics, LLC, an AbbVie Company, Sunnyvale, United States, [11]University of Ulm, Ulm, Germany

Background: Anemia and fatigue are frequent indications for WM treatment. To date, patient-reported outcomes (PROs) have not been used to quantify benefits of any WM treatment. Ibrutinib (ibr), a first-in-class, once-daily inhibitor of BTK, is indicated in the EU for the treamtent of WM after ≥1 prior therapy or first-line in patients (pts) unsuitable for chemoimmunotherapy.
Aims: To prospectively collect PROs from the iNNOVATE substudy to assess patients' perspectives of the therapeutic benefit of ibr.
Methods: INNOVATE has randomized (ibr+rituximab [RTX] *vs* placebo+RTX) and substudy (RTX-refractory) components. Pts in the substudy received oral ibr 420mg daily until progressive disease (PD) or unacceptable toxicity. All pts provided informed consent. PRO assessments—FACT-An total score (TS) and FACT-An anemia subscale (AS), and EQ-5D-5L (EQ)—were performed regularly.
Results: Persistent fatigue was the main indication for treatment in 22/31 (71%) pts. Baseline PRO scores were lower for the substudy *vs* randomized pts (Table). With a median of 17 months (mo) of treatment, most pts had clinically meaningful improvement in TS (≥7 points; 77%), AS (≥6 points; 84%), and EQ utility scores (≥0.08 points; 68%). Time to clinically meaningful improvement was prompt (1 mo for TS and AS; 2 mo for EQ), corresponding with a 48% decline in median IgM (median 20 g/L) after 4 weeks. In pts with baseline anemia (hemoglobin [Hb] ≤110 g/L), sustained Hb improvement increased with depth of response. At week 65, Hb levels significantly correlated with TS (r=0.507, P=0.01) and AS (r=0.519, P=0.008), and were marginal for EQ (r=0.39, P=0.054). Although IgM levels did not significantly correlate with PRO scores, the benefit was similar in responders regardless of depth of response.

Benevolo[2], A. Palumbo[4], P. Sonneveld[5], M. Boccadoro[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, [3]Unit of Clinical Epidemiology, AOU Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy, [4]Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co., Torino, Zurich, Italy, Switzerland, [5]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: Cardio-vascular (CV) toxicities in patients (pts) with multiple myeloma (MM) may derive from comorbidities, MM itself and its treatment. Carfilzomib, an irreversible proteasome inhibitor, is approved as single agent or in combination with dexamethasone or lenalidomide-dexamethasone for relapsed MM.
Aims: We conducted an integrated analysis of CV adverse events (AE) in newly diagnosed, transplant-ineligible MM patients treated with Carfilzomib in 3 phase I/II studies (IST-CAR-506, IST-CAR-561, IST-CAR-601).
Methods: All pts were treated with 9, 28-day induction cycles with carfilzomib, cyclophosphamide (300mg/m^2 on days 1,8,15) and dexamethasone (40mg weekly) (CCyd), followed by carfilzomib maintenance until progression or intol-

erance. Carfilzomib was administered i.v. at the dose of 36mg/m^2 on days 1, 2, 8, 9, 15, 16 in the IST-CAR-506 trial; at 3 dose levels escalated from 45 to 70mg/m^2 on days 1, 8, 15 in the IST-CAR-561 trial and on days 1, 2, 8, 9, 15, 16 in the IST-CAR-601 trial. AEs were graded based on NCI-CTCAE v4.
Results: 148 pts with a median age of 72 years were analyzed. At enrollment, 34% of patients had at least 1 cardiovascular risk factor: 20% had peripheral vascular disease (including hypertension in 13% patients), 19% diabetes and 5% chronic pulmonary disease. After a median follow-up of 21 months, at least 1 any grade CV-AE occurred in 45% of patients; any grade hypertension was reported in 17% of patients, dyspnea in 9%, and heart failure, arrhythmia and venous thromboembolism (VTE) in 6% of patients, each. Grade 3-5 CV-AEs occurred in 15% of patients, the most common being heart failure (4%), hypertension (3%), pulmonary edema (3%) and VTE (3%). Four (3%) fatal CV-AEs occurred: 1 case of heart failure, pulmonary edema, arrhythmia and VTE, respectively. No difference in terms of CV-AEs was observed in patients treated with different doses of carfilzomib. In pts who developed at least 1 CV-AE, carfilzomib dose reduction (33%) and discontinuation (33%) were more frequent as compared to those without CV-AEs (12% and 18%, respectively; p<0.0001). A trend toward a shorter 2-year overall survival (adjusted for age) was observed among patients who experienced at least 1 CV-AE as compared with those who did not (74% *vs* 83%, HR: 0.51; p=0.066). Pts ≥75 years had a higher risk of any grade (58% *vs* 36%, p=0.02) and grade 3-5 CV-AEs (34% *vs* 15%, p=0.01); major cardiac events of any grade were more frequent in older patients (29%) than in younger ones (6%; p<0.001). Patients with at least 1 CV risk factor at enrolment had a 4-fold increased risk (odds ratio: 3.79; p<0.001) of developing a CV-AE during treatment as compared to patients with no CV risk factors: in detail, baseline hypertension (odds ratio: 4.12; p=0.012) and peripheral vascular disease (odds ratio: 3.75; p=0.002) conferred the highest risk of developing CV-AEs.

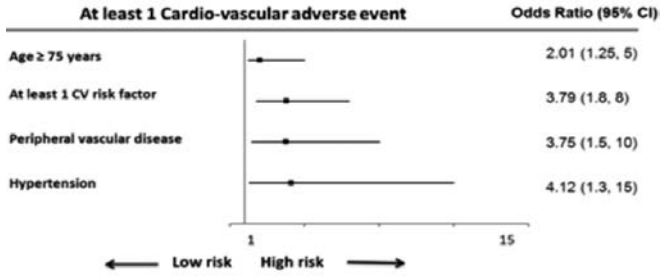

Figure 1.

Summary/Conclusions: Among newly diagnosed MM pts treated with carfilzomib, cyclophosphamide and dexamethasone, at least 1 CV-AE occurred in 45% of pts, hypertension and dyspnea were the most common. Pts ≥75 years of age and those with at least 1 pre-existing CV risk factor were at higher risk of developing a CV-AEs. The onset of CV toxicity significantly increased the rate of dose reductions and treatment discontinuation, translating into higher risk of death. CV toxicity may significantly impact on treatment compliance and survival. Therefore, to derive maximum benefit from Carfilzomib, all pts - particularly the elderly - should be carefully assessed to select the most appropriate treatment.

E1248

POMALIDOMIDE (POM) + LOW-DOSE DEXAMETHASONE (LODEX) AFTER SECOND-LINE LENALIDOMIDE (LEN)-BASED TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED PROGRESSION-FREE SURVIVAL ANALYSIS

D.S. Siegel[1,*], G.J. Schiller[2], K. Song[3], R. Agajanian[4], K. Stockerl-Goldstein[5], H. Kaya[6], M. Sebag[7], F.J. Reu[8], E. Malek[9], G. Talamo[10], J. Mouro[11], W. Chung[11], S. Srinivasan[11], M. Qian[11], S. Rizvi[11], A. Thakurta[11], N.J. Bahlis[12]
[1]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, United States, [3]Vancouver General Hospital, Vancouver, BC, Canada, [4]The Oncology Institute of Hope and Innovation, Downey, CA, [5]Washington University School of Medicine, St. Louis, MO, [6]Cancer Care Northwest, Spokane, WA, United States, [7]McGill University Health Centre, Montreal, Quebec, Canada, [8]Cleveland Clinic, [9]University Hospitals Case Medical Center, Cleveland, OH, [10]Penn State Hershey Cancer Institute, Hershey, PA, [11]Celgene Corporation, Summit, NJ, United States, [12]University of Calgary, Calgary, Alberta, Canada

Background: Most recent pivotal trials of triple therapy in second- and third-line treatment excluded patients (pts) whose multiple myeloma (MM) was refractory to LEN. This is not reflective of the standard of care in first and second line where LEN is given until progressive disease (PD). To address this, the MM-014 phase 2 trial enrolled pts with RRMM and second-line LEN-based treatment failure. Cohort A enrolled pts treated with POM + LoDEX. The study was amended to include cohort B (pts treated with POM + LoDEX + daratumumab).
Aims: To present updated safety and efficacy analyses only from cohort A, in which pts received POM + LoDEX immediately after relapsing or being refractory to second-line LEN-based therapy.
Methods: Pts aged ≥18 years had documented MM, measurable disease, 2 prior lines of treatment, and PD after ≥2 cycles of second-line LEN-based treatment. Pts received 28-day cycles of POM 4mg/day on days 1-21 + LoDEX 40mg/day (20mg/day if>75 years) on days 1, 8, 15, and 22; thromboprophylaxis was mandatory. The primary endpoint was overall response rate (ORR; ≥ partial response [PR]) assessed by modified IMWG criteria. Key secondary endpoints included time to response (TTR), progression-free survival (PFS), secondary primary malignancies (SPMs), and biomarkers. All pts provided informed consent.
Results: Of 51 enrolled pts in cohort A, 39 (76.5%) discontinued treatment, mostly due to PD. Median age was 68.0 years, and 92.2% had an Eastern Cooperative Oncology Group performance status of ≤1. A total of 45 pts (88.2%) were refractory to their last treatment with LEN, and 37 (72.5%) had prior treatment with bortezomib. Median duration of prior LEN-containing therapy was 24.6 months. With a median follow-up of 13.6 months, ORR was 29.4%, with 1 (2.0%) complete response, 5 (9.8%) very good partial responses, and 9 (17.6%) PRs. Minimal response (MR) was reached in 15.7% of pts. Median TTR was 1.9 months and 66% of pts had ongoing response at 1 year. Median PFS was 13.8 months. The 2-year PFS rate was 48.6% for the intent to treat population, 69.4% for pts with ≥ MR, and 69.1% for pts with ≥ PR. In addition, pts with ≥ MR had similar treatment durations as those achieving ≥ PR (10.5 *vs* 11.5 months; Table). Common grade 3/4 adverse events (AEs) included anemia (25.5%), neutropenia (11.8%), and infections (19.6%; including pneumonia [9.8%]). No pts experienced SPMs. In the immune subset analysis, the proportions of CD3$^+$ and CD3$^+$/CD8$^+$ T cells after treatment were significantly higher *vs* baseline (72.6% *vs* 67.8% and 36.9% *vs* 32.1%, respectively; *P*<.05). Pts with response also had significantly elevated proportions of these T-cell populations, but pts with no response did not. Relative changes from baseline for CD3$^+$ and CD3$^+$/CD4$^+$T-cell populations were significantly greater in pts with response *vs* those with no response (10.4 *vs* −0.8 and 4.2 *vs* −3.5, respectively; *P*<.05).

Table 1.

Response Type	POM Treatment Duration, months
≥ PR (n = 15)	11.5
≥ MR (n = 23)	10.5
MR (n = 8)	7.7
Stable disease (n = 21)	3.7

Summary/Conclusions: This update confirms the safety and efficacy of POM + LoDEX following second-line LEN-based treatment failure in pts with RRMM. Hematologic AE rates improved, and median PFS was longer with third-line use than previously reported with POM + LoDEX use in later treatment lines. In addition, achieving disease control of ≥ MR led to similar PFS rates as reaching ≥ PR.

E1249

"REAL WORLD" DATA ON THE EFFICACY AND SAFETY OF IXAZOMIB IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: A STUDY OF THE GREEK MYELOMA STUDY GROUP

E. Terpos[1,*], E. Katodritou[2], M. Kotsopoulou[3], I. Ntanasis-Stathopoulos[1], P. Lampropoulou[3], S. Papadaki[2], M. Papathanasiou[4], D. Stoumbos[3], M. Gavriatopoulou[1], P. Repousis[3], E. Kastritis[1], M.A. Dimopoulos[1]
[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, [2]Department of Hematology, Theagenion Cancer Hospital, Thessaloniki, [3]Department of Hematology, Metaxa Cancer Hospital, Piraeus, [4]Department of Hematology and Bone Marrow Transplantation Unit, G. Papanikolaou General Hospital, Thessaloniki, Greece

Background: The all-oral combination of ixazomib, lenalidomide and dexamethasone (IRd) has been recently approved as a novel standard of care for relapsed/refractory multiple myeloma (RRMM).
Aims: The aim of this study was to evaluate the efficacy and safety of IRd in the "Real World" (RW) practice, where data are very limited.
Methods: This was a retrospective, non-interventional study, which recorded IRd treatment data from patients with RRMM who participated in the name-patient program of ixazomib in Greece. The primary endpoint was the evaluation of overall response rate (ORR), according to IMWG criteria. Secondary endpoints included: treatment duration; time to response; duration of response; percentage of patients who experienced adverse events (AEs), needed dose modification or treatment discontinuation; evaluation of PFS and TTP.
Results: Forty-one patients were included in the present study. Of those, 35 (19M/16F, median age 70.5 years (range: 63-79 years) had received at least 3 cycles of IRd on the date of data analysis and thus they were included in the present report. The median line of previous therapies was one (range: 1-5): 71.4% (25/35) patients had received one prior treatment, while 20.0% (7/35),

5.7% (2/35) and 2.9% (1/35) had received 2, 3 and 5 prior treatment lines, respectively. Overall, 82.9% (29/35) of patients had been exposed to proteasome inhibitors prior to IRd (77.1% to bortezomib and 8.6% to carfilzomib] and 48.6% (17/35) to IMiDs [31.4% (11/35) to thalidomide and 22.9% (8/35) to lenalidomide]. Autologous transplantation had been given in 42.9% (15/35) of patients. Median treatment duration was 7.1 months. Among 34 patients with available data for response, VGPR was recorded in 35.3% (12/34), PR in 32.4% (11/34), MR in 2.9% (1/34) and stable disease in 26.5% (9/34). The ORR (PR or better) was 67.6%: 70.8% among those who received IRd in the second line and 60.0% among those who received IRd beyond the second line;ORR tended to be higher as the time of exposure to ixazomib increased, with patients exposed to ixazomib for at least 6, 7 and 8 months, noting ORR rates of 70.8% (17/24), 76.5% (13/17) and 91.8% (9/11), respectively. Median time to best response was 1.2 months. Treatment interruptions due to AEs were recorded for 11.4% (4/35) of patients, while 20.0% (7/35) of patients discontinued treatment. Reasons for ixazomib discontinuation were AEs for 3 patients (an event of septic shock had fatal outcome), disease progression in 3 patients and administrative reason (patient could no longer visit the site) in one. Among the 35 patients analyzed, 17.1% (6/35) had experienced disease progression or death; the 6-month PFS rate was 90.5% and the 6-month TTP rate was 93.2%. Regarding AEs of interest, 31.4% (11/35) of patients experienced peripheral neuropathy; of those events, 54.5% (6/11) resolved, while 45.4% (5/11) had not resolved (three were grade 1, one grade 2, and one of grade 3) at the end of follow-up. In addition, 31.4% (11/35) of patients developed gastrointestinal AEs, 11.4% (4/35) experienced pneumonia, 9.4% (3/32) hypertension, 5.7% (2/35) cataract and herpes zoster, and 2.9% (1/35) deep vein thrombosis; no cardiac arrhythmia or other cardiac events were recorded, while osteonecrosis of the jaw developed in 5.7% (2/35) of the patients.

Summary/Conclusions: This study showed that the IRd regimen produces an ORR of near 68% and a clinical benefit in almost all patients with RRMM who are treated in RW practice. IRd acts rapidly and has an acceptable toxicity profile with no cardiac events.

Orsola, Malpighi, Bologna, Italy, [6]University Hospital Ostrava and Faculty of Medicine Ostrava, Ostrava, Czech Republic, [7]University Medical Center Utrecht, Utrecht, Netherlands, [8]National and Kapodistrian University of Athens, Athens, Greece, [9]Centre Hospitalier Universitaire de Liège, Liege, Belgium, [10]Aarhus University Hospital, Aarhus, Denmark, [11]Uddevalla Sjukhus, Uddevalla, Sweden, [12]St Olav's Hospital, Trondheim University Trondheim, Trondheim, Norway, [13]Midland Regional Hospital, Tullamore, Ireland, [14]Celgene International, Boudry, Switzerland, [15]Department of Internal Medicine III, Charité Campus Benjamin Franklin, Berlin, Germany

Background: EU PASS is an observational, non-interventional study designed to investigate the safety of lenalidomide (LEN) and other agents in the treatment of patients with RRMM in a real-world setting.

Aims: To assess the incidence of adverse events (AEs) of special interest (ie, neutropenia, thrombocytopenia, venous thromboembolism [VTE], neuropathy, and second primary malignancies [SPMs]).

Methods: Patients with RRMM initiating LEN treatment were enrolled at the investigator's discretion into the LEN cohort (LEN + dexamethasone, the approved combination for the treatment of RRMM); patients who received ≥ 1 prior therapy initiating a non–LEN-based treatment were enrolled into a background cohort (all other treatments, including novel agents). Thromboprophylaxis was administered per local standard practice. AEs were graded per the National Cancer Institute-Common Terminology Criteria for AEs, v3.0. SPMs were defined using MedDRA terms, SPM assessments were to be conducted up to 36 mos after treatment discontinuation (Protocol amendment 2011). All patients provided informed consent.

Results: As of March 1, 2016, 3630 patients were included in the safety population. Of these patients, 2151 (59.3%) received LEN, 1187 (32.7%) received bortezomib (BORT), 137 (3.8%) received thalidomide (THAL), and 155 (4.3%) received other therapies. The median duration on study treatment was 6.6 mos (range 0.1-79.9 mos) for patients receiving LEN, 4.1 mos (range 0-61.4 mos) for BORT, and 4.6 mos (range 0.2-36.9 mos) for THAL. At the time of analysis, 3557 patients (98.0%) had discontinued treatment. Of the 73 patients (2.0%) who were on treatment, 63 were treated with LEN, 6 with BORT, 0 with THAL, and 4 with other therapies. Baseline characteristics were balanced across cohorts. Median age was 70 yrs (range 25-95 yrs) and 54.0% of patients were male. Of 2985 patients with available ECOG scores, 2865 (96.0%) had an ECOG score ≤2. The median number of prior therapies was 1 (range 1-6); the proportion of patients with only 1 prior treatment was lower in the LEN (44.2%) *vs* BORT (70.8%) and THAL (56.2%) cohorts. Overall, 1843 patients (50.8%) had grade 3/4 AEs (Table). All grade neuropathy occurred in 9.8%, 28.2%, and 17.5%, and VTE occurred at 6.0%, 1.3%, and 0% of patients in the LEN, BORT, and THAL cohorts. The incidence of SPMs per 100 patient-years was 3.87 overall and 3.45, 5.41, 2.73, and 6.51 for LEN, BORT, THAL, and other agents, respectively. Treatment discontinuation rates due to AEs were similar in each cohort (LEN: 22.4%; BORT: 20.1%; and THAL: 21.2%). Rates of treatment-emergent AEs leading to dose reductions were also similar across cohorts, occurring in 23.9% of patients in the LEN cohort, 21.2% in BORT, and 17.5% in THAL. Data on long-term responders will be presented at this meeting.

Table 1.

Grade 3/4 AEs, %	LEN	BORT	THAL
Neutropenia	20.0	4.5	7.3
Febrile neutropenia	1.5	0.4	1.5
Thrombocytopenia	10.0	8.4	3.6

AE, adverse event; BORT, bortezomib; LEN, lenalidomide; THAL, thalidomide.

Summary/Conclusions: LEN was generally well tolerated and the safety results were similar to published data. As expected, the occurrence of neutropenia, TCP, and VTEs were higher in patients in the LEN cohort, whereas neuropathy was more frequently reported in patients in the BORT cohort. VTEs were low in all cohorts. The occurrence of SPMs was generally low and comparable between cohorts.

E1251

NEW CLINICAL PATHWAYS OF THE CENTERS OF EXCELLENCE NETWORK IN GERMANY: A NEW CONCEPT FOR STANDARDIZED CARE OF MULTIPLE MYELOMA PATIENTS

J.-P. Glossmann[1,*], C. Scheid[2], M. Engelhardt[3], H. Goldschmidt[4], H. Einsele[5], B. Starbatty[1], M. Bischoff[6], M. Follmann[7], N. Skoetz[1]

[1]CIO Köln Bonn, University Hospital of Cologne, [2]Kerpener Str. 62, Department I of Internal Medicine, CIO Köln Bonn, University Hospital of Cologne, Cologne, [3]Department of Medicine I, Hematology,Oncology & Stem Cell Transplant, University of Freiburg, Freiburg, [4]Department of Medicine V, University of Heidelberg, Heidelberg, [5]Department of Internal Medicine II, University Hospital Wuerzburg, Wuerzburg, [6]Institute for Medical Biometry and Statistics, University of Freiburg, Freiburg, [7]German Guideline Program in Oncology, German Cancer Society, Berlin, Germany

Background: Clinical outcome of multiple myeloma (MM) patients is heterogeneous and depends on various prognostic factors and available treatments. Although tremendous progress has been made in MM, so far, there is no national or international evidence-based guideline giving recommendations for clinical practice in the treatment of MM patients. In Germany, 14 Comprehensive Cancer Centers (CCC) are funded as 'Centers of Excellence' by the German Cancer Aid (DKH). All these Centers of Excellence are required to develop and provide in-house clinical pathways for standards in cancer care. These pathways include concise diagnostic and therapeutic instructions, reflecting available evidence-based recommendations. In addition, ongoing studies (in particular phase I / II) are part of clinical pathways, so that a rapid transfer of innovation is provided and patients gain access to new therapeutic approaches. The Centers of Excellence Network working group SOP has the goal to harmonize these hospital specific in-house clinical pathways differing in format, content and level of detail of guidance.

Aims: The project's objective is to harmonize diagnosis, treatment and follow-up of all MM patients in Germany by providing concise, freely available online clinical pathways.

Methods: The clinical pathway was prepared according to a methods handbook developed by the working group including recommendations for standardized methodology and evidence processing. Intensive collaboration of clinical and methodological experts in the multi-disciplinary working-group, together with experts from both German Study Groups Multiple Myeloma and the German-speaking Multicenter Myeloma Group ensured clinically relevant and up-to-date pathway drafts. In a first step, information from all available in-house clinical pathways was used as a first harmonized draft. Experts from four leading centers in the field of myeloma research and treatment in Germany (Cologne, Freiburg, Heidelberg, Wuerzburg) agreed after intense discussion during face-to-face meetings and after including latest research results from literature searches into one pathway. The resulting pathway draft was discussed with experts from all 14 Centers of Excellence during face-to-face meetings, conference calls and two online surveys until consensus was reached. The project is funded by the DKH, No. 111493.

Results: During the development process, a number of similarities and discrepancies between centers as well as evidence gaps were identified. Intense discussion and literature searches resulted in a concise, harmonized clinical pathway, released by all 14 Centers of Excellence. This is freely available on the website ccc-netzwerk.de and provides a very decisive insight according to the current state of knowledge on the CCC-level (e.g. on the diagnostic algorithm, Fig. 1). The clinical pathway is well suited for informing patients and physicians about the most up-to-date, comprehensive medical treatment standards as well as innovative procedures. Furthermore, this project initiated the idea of developing a national evidence-based clinical practice guideline for MM in the frame of the German Guideline Program in Oncology.

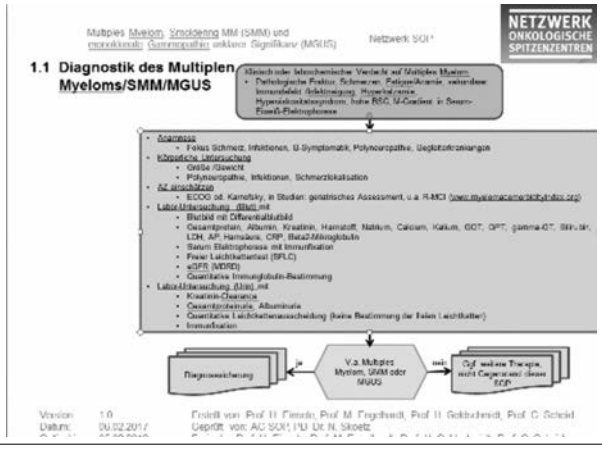

Figure 1.

Summary/Conclusions: The first clinical MM pathway developed and released by all 14 German CCCs/Centers of Excellence translates scientific evidence and expert knowledge into precise suggestions for MM patients in clinical practice. These harmonized processes might increase the quality of cancer care throughout Germany. To be up-to-date and to reflect latest research findings this clinical pathway will be updated every 18 months.

E1252

WT1 HETEROCLITIC EPITOPE IMMUNIZATION FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA (MM)

G. Koehne[1,*], S. Devlin[1], D. Chung[1], H. Landau[1], N. Korde[1], S. Mailankody[1], H. Hassoun[1], A. Lesokhin[1], N. Lendvai[1], S. Giralt[1], O. Landgren[1]
[1]Memorial Sloan Kettering Cancer Center, New York, United States

Background: The Wilms tumor 1 (WT1) protein is a tumor associated antigen that is a target for anticancer immunotherapy. We had previously demonstrated overexpression of WT1 in multiple myeloma (MM) cells by IHC, as well as formation of a WT1 peptide fragment (RMFPNAPYL)/HLA-A*0201 complex on the engagement interface between malignant plasma cells and T-cells in HLA-A*0201$^+$ MM pts using the high-affinity fully human IgG1 mAb ESK1. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT.
Aims: To determine the safety and potential efficacy of the WT1 heteroclitic peptide immunizer GPS administered in patients with multiple myeloma following autologous stem cell transplantation.
Methods: 16 MM pts underwent autoSCT with melphalan conditioning followed by (f/b) lenalidomide maintenance starting 3 months (mos) post-SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del17p, 1q21/25 gain and/or del13q]. GPS was administered with montanide s.c. starting 2 wks post-SCT and q.2 wks thereafter x 6 initial doses f/b boosters q.4 wks x 6 additional doses. GM-CSF was given on days -2 and 0 of each cycle. GPS consisted of 4 peptides: WT1-A1: Y*MFPNAPYL; 427-L (long): RSDELVRHHNMHQRNMTKL; 331-L: PGCNKRYFKLSHLQMHSRKHTG, and 122A1-L: SGQAY*MFPNAPYLPSCLES. 2 of the 4 peptides were mutated at a single residue (*) to induce stronger HLA-binding/reduce tolerance. WT1-specific immune responses (IRs) were assessed by intracellular IFN-g analyses post-challenge with PBMC's pulsed with a 'total pool' of overlapping 15mers along the entire WT1 protein; or each of the 4 WT1 peptides in GPS; or the non-mutated (native) WT1 peptides corresponding to the 2 heteroclitic sequences.
Results: 16 pts underwent auto SCT followed by WT1 heteroclitic peptide immunization; median follow-up of 18 mos (range: 5-31 mos) for survivors; median age: 61.6 y. Overall survival (OS) and progression-free survival (PFS) (95% CI) at 18 mos: 0.88 (0.73-0.99) and 0.62 (0.42-0.97) respectively. Current median PFS: 23.6 mos (15.2- not reached). No ≥G2 systemic side effects were observed, however, all pts developed local nodularity at the site of injections which resolved over 2 – 6 wks. Both CD8+ and CD4+ IRs could be detected at various levels and were induced not only against the heteroclitic peptides (within GPS), but also against the corresponding native WT1 peptide sequences as well as the 'total pool' of WT1-derived overlapping peptides.
Summary/Conclusions: Administration of the novel WT1 heteroclitic peptide immunizer GPS post-SCT demonstrates favorable safety profile along with an encouraging mPFS of currently 23.6 mos in this high-risk MM population. This 'off-the-shelf' immunotherapeutic is easy to administer and has been specifically designed to elicit responses across most common HLA Class I and II alleles. Based on these results, a larger phase II trial is being planned to optimally integrate post-transplant immunotherapeutic strategies to meaningfully delay or reduce risk of relapse in this challenging clinical setting.

E1253

ANALYSIS OF MULTIPLE MYELOMA PATIENTS WITH PROGRESSIVE DISEASE AT TIME OF FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION: PREDICTORS OF PROGRESSIVE DISEASE AND FACTORS AFFECTING SURVIVAL

J. Blocka[1,*], H. Goldschmidt[1], T. Hielscher[2], M. Pritsch[1], M. Raab[1], J. Hillengass[1]
[1]University Hospital Heidelberg, [2]German Cancer Research Center, Heidelberg, Germany

Background: The impact of response depth at time of autologous stem cell transplantation (ASCT) on the progression-free and overall survival (PFS and OS, respectively) of multiple myeloma (MM) patients has been an extensively investigated area. Rosiñol et el. (2011) reported a significantly worse PFS and OS in patients with progressive disease (PD) compared to stable disease (SD) at time of ASCT; Parrish *et al.* (2015) stated a significantly shorter PFS, but not OS, in patients with PD in comparison to SD or minimal response (MR) at time of ASCT.
Aims: Our goal was to characterize MM patients with PD at time of first ASCT. We aimed to analyze the effects of PD on PFS and OS. Next, we intended to examine the influence of clinical factors (evaluated at beginning of induction therapy) as well as use of novel agents in induction therapy, response after 1st ASCT, and use of maintenance therapy in those patients to identify predictors for PFS and OS. Furthermore, we aimed to identify clinical/ therapeutic features predicting the occurrence of PD before ASCT.
Methods: Non-trial MM patients who had undergone a single or tandem ASCT at the University Hospital of Heidelberg in the years 1992-2014 were analyzed regarding their response before 1st ASCT (d -100 or, if available, response as close to the date of ASCT as possible, *i.e.* until d -4). Of the 874 ASCT-patients, 829 were eligible for a PFS- and 832 for an OS-analysis. In 51 patients, PD was present at time of ASCT. PFS and OS of those patients were compared with the survival of patients with at least SD at time of ASCT (non-PD patients). Furthermore, clinical factors at beginning of induction therapy, including age (< *vs* ≥ 65 years), ISS stage, elevated LDH, use of novel agents in induction therapy, high-risk FISH cytogenetics (at least one of the following: del17p, 1q21 gain, t(4;14)); response after ASCT, and maintenance therapy (yes *vs* no) were analyzed regarding their impact on PFS and OS of patients transplanted in PD. We also analyzed clinical factors at beginning of as well as use of novel agents in the induction therapy regarding their impact on the presence of PD before ASCT. Response was evaluated according to EBMT-criteria. PFS was calculated from date of 1st ASCT, except for prognostic impact of response assessment after 1st ASCT, where date of response assessment was used. Start of maintenance therapy was analyzed as time-dependent factor.
Results: Non-trial patients transplanted in our center between 1992 and 2014 with PD ≤100 days before ASCT had similar PFS and OS as non-PD patients. Neither the clinical parameters at induction start, response after 1st ASCT, nor maintenance therapy had a significant effect on PFS in those patients. In the univariate analysis, high-risk cytogenetics as well as elevated LDH at induction start had a significantly negative effect on OS in patients with PD before ASCT (HR= 17.12, p= 0.0017; HR=6.09, p= 0.01, respectively), compared to PD-patients with no high-risk cytogenetics or with normal LDH. Furthermore, ISS stage III was a significant predictor (OR= 3.35, p= 0.02)) of occurrence of PD before ASCT.
Summary/Conclusions: In conclusion, our analysis of 51 patients with PD at time of ASCT- among 874 ASCT-patients with MM transplanted between 1992 and 2014- shows no significant difference regarding PFS and OS between patients with PD and other response rates. It was further shown that high-risk cytogenetics as well as elevated LDH at beginning of induction therapy have a significant impact on worse OS in patients with PD at time of ASCT. In addition, ISS stage III is a significant factor for occurrence of PD before ASCT. The impact response depth at time of ASCT is not entirely clear, especially regarding the benefit of ASCT in patients with PD at time of ASCT, as reports from other centers show significantly worse PFS and OS (Rosiñol et al.) or only PFS (Parrish et al.) in patients with PD at time of ASCT.

E1254

SEVERE INFECTIONS IMPACTS OVERALL SURVIVAL IN ACTIVE MULTIPLE MYELOMA PATIENTS

G. Barila'[1,*], C. Nicolo'[1], A. Liço[1], A. Branca[1], L. Checuz[1], E. De March[1],

L. Ammirati[1], T. Berno[1], M. Leoncin[1], F. Cinetto[1], C. Agostini[1], F. Piazza[1], G. Semenzato[1], R. Zambello[1]
[1]Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, Padua, Italy

Background: Multiple myeloma (MM) represents the second most common hematological malignancy characterized by the proliferation of monoclonal plasma cells (PC) in the bone marrow. The natural history of active MM patients may be complicated in significant fraction by the occurrence of infections that can be related both to the development of therapy induced neutropenia (mainly due to high dose chemotherapy used in the setting of autologous stem cell transplantation or in salvage regimen) or to MM induced secondary immunodeficiency.
Aims: The aim of this study was to analyse the frequency, the type and the major risks factors of severe infections in our cohort of patients affected by MM and to understand the impact of these events on MM patient overall survival (OS).
Methods: A cohort of 341 patients affected by MM (104 with smouldering MM and 237 with symptomatic MM) followed from 1996 to 2016 was retrospectively studied for the presence of severe infections (si, defined by the need of hospitalization) during the natural history of the disease. Infections were classified as "not neutropenia related" or "neutropenia related" according to the Absolute Neutrophil Count > or <1,000/ml respectively. International Staging System (ISS) and Durie-Salmon (DS) were used for MM patients staging.
Results: In our cohort of patients, si were significantly associated to active MM (28,69% of symptomatic patients *vs* 3,85% of asymptomatic patients; p=0.0001, c^2=25,318). Among the 138 infective events occurred in 91 active MM patients, 38 (28%) were neutropenia related while remnant 100 not neutropenia related (72%). Furthermore, almost 44% of these events (61/138) developed during induction therapy, with 12 out of 61 (20%) being present at time of the diagnosis. Considering that majority of si was not neutropenia related and that these infective events involved most of active MM patients who developed si (68/91, 75%), our aim was to identify MM patient characteristics associated to the development of not neutropenia related si. Our results prove evidence that major features presented at the time of the diagnosis significantly associated to si were DS stage III (p=0.0004, c^2=12,14), ISS stage III (p=0.0001, c^2=21,11), age >70 years (p=0.0195, c^2=5,455), bone marrow plasma cells >60% (p=0.034, c^2=4,50), acute renal failure (p=0.0003, c^2=13,010) or MM presenting with at least three of CRAB criteria (p=0.0123, c^2=6,26). For what concern the impact of si on the natural history of the disease, patients who experienced infective event presented a reduced OS towards other patients (p<0.0001). Among infected patients no significant differences were reported referring to the number of infections (>1 or =1, p=0.11), while patients who developed exclusively neutropenia related infective events showed better OS towards patients who experienced not neutropenia related infections (p=0.0011).

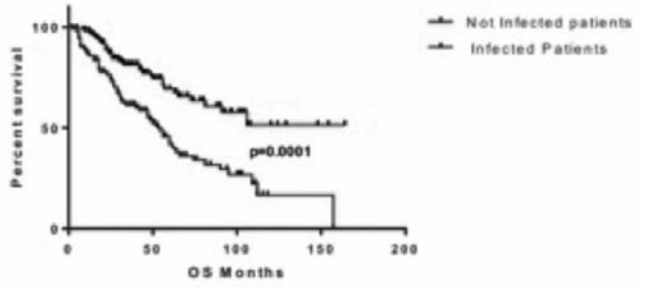

Figure 1.

Summary/Conclusions: Severe infections represent an underestimated comorbidity in MM, characterizing all phases of the disease and not only refractory/relapsed patients receiving multiple lines of therapy. Considering that severe infections impact OS mostly in the setting of not neutropenia related infections, immunoglobulin replacement therapy or antibiotic prophylaxis may possibly have a protective role in high risk old patients characterized by ISS and DS stage III, bone marrow PC >60% and aggressive disease at the time of diagnosis.

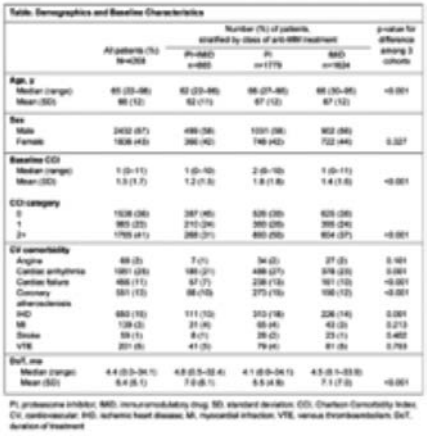
E1255

EVALUATION OF CARDIOVASCULAR EVENTS ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF MULTIPLE MYELOMA IN THE REAL-WORLD SETTING IN THE UNITED STATES

D. Lenihan[1], R. Potluri[2], H. Kanakamedala[2], A. Dasgupta[2], C. Chen[3,*]
[1]Vanderbilt University Medical Center, Nashville, [2]SmartAnalyst Inc., New York, [3]Bristol-Myers Squibb, Lawrenceville, United States

Background: Multiple myeloma (MM) is a disease of the elderly. The prevalence of cardiovascular (CV) comorbidities in the MM population is high. Past research suggests that MM is associated with a range of cardiac risks, and emerging evidence shows that both proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) can have important CV sequelae. The improved efficacy of PI plus IMiD combination therapy (PI+IMiD) has resulted in its widespread adoption, which suggests that CV events may become a prominent concern in patients receiving PI+IMiD as contemporary treatment for MM.
Aims: To assess the risk of developing CV events in patients receiving anti-MM treatment and to test if a specific treatment modality was associated with higher risk of a CV event.
Methods: Patients with ≥1 inpatient claim or ≥2 outpatient claims with a primary diagnosis code for MM who were treated with PI and/or IMiD drugs between Jul 2012 and Sep 2014 were identified in a large US claims database. The first claim for a PI or IMiD drug in this period was defined as the index date, which was preceded by 180-d continuous eligibility with no anti-MM treatment (baseline). Patients were divided into three cohorts based on the anti-MM treatment received: PI, IMiD, PI+IMiD. CV events of interest included cardiac arrhythmia, cardiac failure, venous thromboembolism (VTE), myocardial infarction, ischemic heart disease, angina, stroke and coronary atherosclerosis, and were measured during anti-MM treatment. Kaplan–Meier methods were used to estimate the occurrence rate of a CV event, and multivariate Cox regression models were developed to identify prognostic factors of each CV event among patients treated with anti-MM therapies.
Results: 4268 patients met the eligibility criteria for inclusion in the study (57% male, median age 66 y, 41% with Charlson Comorbidity Index ≥2, mean duration of treatment 192 d; Table), 42% (n=1779) were treated with PIs, 38% (n=1624) with IMiDs and 20% (n=865) with PI+IMiDs. Patients receiving PI+IMiD were significantly younger and generally had lower prevalence of CV comorbidities than those receiving PI or IMiD (Table). Compared with patients on PI, the risk of developing VTE was 46% greater in patients on PI+IMiD (HR: 1.46; 95% CI: 1.09, 1.96). Compared with those on IMiD, the risk of developing cardiac failure and cardiac arrhythmia was 33% and 18% greater in patients on PI+IMiD (HR: 1.33; 95% CI: 1.03, 1.72; HR: 1.18; 95% CI: 1.00, 1.40). After 6 months of treatment, the rates of VTE were 8%, 10% and 11% for patients on a PI, those on an IMiD and those on PI+IMiD, respectively. The corresponding rates for cardiac failure were 18%, 11% and 11% for PI, IMiD and PI+IMiD cohorts, and 21%, 16% and 22% for cardiac arrhythmia.

Table 1.



Summary/Conclusions: PI+IMiDs may be associated with incremental occurrence of specific CV events during treatment, and may result in specific CV events earlier during therapy than PIs or IMiDs alone. These highlight a need for treatments that do not exacerbate CV risks and are appropriate for patients with pre-existing CV conditions. The lower prevalence of baseline CV comorbidities and lower mean age in patients on PI+IMiDs suggest that prevalence of a CV comorbidity and age influences treatment choice. Further analysis may be necessary to better understand the impact of baseline CV comorbidities on choice of MM treatment.

E1256

LENALIDOMIDE PLUS HIGH-DOSE *VERSUS* LOW-DOSE DEXAMETHASONE FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA: A SYSTEMATIC REVIEW

K. Kupas[1,*], I. Kaspar[1], V. Baecke[2], K. Weisel[3]
[1]Bristol-Myers Squibb, Munich, [2]Ecker + Ecker GmbH, Hamburg, [3]University of Tübingen, Tübingen, Germany

Background: Lenalidomide in combination with dexamethasone is approved globally for the treatment of multiple myeloma (MM). Although older pivotal registrational studies used lenalidomide combined with high-dose dexamethasone (LD), more recent studies have used lenalidomide plus low-dose dexamethasone (Ld) for relapsed/refractory MM (RRMM), as the Ld regimen demonstrated better survival with lower toxicity for the treatment of newly diagnosed MM

(NDMM; Rajkumar SV *et al. Lancet Oncol* 2010;11:29–37). Additionally, all recent Phase 3 trials establishing new triplet combinations with lenalidomide and dexamethasone in RRMM, such as ELOQUENT-2 (study of elotuzumab plus Ld in RRMM; Lonial S *et al. N Engl J Med* 2015;373:621–31), used the Ld regimen in both standard and experimental arms. Although the lenalidomide label includes Ld for NDMM, there are differences between the approved dose of dexamethasone and what is currently used in real-world clinical practice for RRMM.
Aims: We performed a historical comparison based on a systematic review of literature describing low- *vs* high-dose dexamethasone in patients with RRMM to assess effects of Ld *vs* LD on safety and efficacy outcomes.
Methods: We searched MEDLINE, EMBASE and Cochrane databases and key clinical trial registries for studies including adults with RRMM who had received ≥1 prior therapy and had a symptomatic relapse on their last treatment. Eligible studies evaluated Ld (lenalidomide: 25mg on Day 1–21 of each cycle; dexamethasone: 160mg/cycle, not pulsated) or LD (Cycles 1–4: 480mg/cycle; Cycle 5+: 160mg/cycle, pulsated). Only those trials with designs and baseline patient characteristics similar to ELOQUENT-2 were eligible to ensure comparability. Studies with a follow-up of 16–25 months were evaluated separately from studies with a follow-up of >30 months; these observation periods approximately align with those of ELOQUENT-2.
Results: From an initial bibliographic search yielding 5155 non-duplicate results and 619 registry results, 7 studies (8 publications) met the inclusion criteria (4 Ld studies, 3 LD studies). Data for overall survival and tolerability from 1153 patients in the Ld group and 353 patients in the LD group were analyzed. The median patient age was 63–68 years. Most patients were white, male and had an ECOG score of 0-1. Ld was not associated with loss of efficacy *vs* LD in terms of overall survival; after >30 months of follow-up, the hazard ratio for LD *vs* Ld was 1.04 (95% CI 0.85-1.28). Tolerability was similar for LD *vs* Ld; after 16-25 months of follow-up, LD was associated with a statistically significantly increased risk of Grade 3/4 adverse events (AEs; relative risk [RR]: 1.10 [95% CI 1.01-1.18]). However, after >30 months of follow-up, LD was not associated with an increase in overall AEs (RR: 1.02 [95% CI 1.01-1.03]), grade ≥3 AEs (RR: 1.03 [95% CI 0.95-1.12]) or serious AEs (RR: 1.08 [95% CI 0.97-1.20]); RR for AEs leading to discontinuation was 1.16 (95% CI 0.87-1.54).
Summary/Conclusions: Overall survival and safety are not significantly affected by different dosing of dexamethasone in combination with lenalidomide; thus, the use of Ld seems to be reasonable in this patient population. Further studies may provide additional evidence to inform clinicians and revision of international guidelines for dexamethasone dosing in RRMM.

Study funded by Bristol-Myers Squibb.

E1257

HIGH EFFICACY AND SAFETY OF VTD AS AN INDUCTION PROTOCOL IN NEWLY DIAGNOSED MM PATIENTS ELIGIBLE FOR HDT/AUTOSCT – A REPORT OF POLISH MULTIPLE MYELOMA STUDY GROUP

I. Hus[1,*], J. Manko[2], D. Jawniak[2], A. Jurczyszyn[3], L. Usnarska-Zubkiewicz[4], M. Sawicki[4], G. Charlinski[5], M. Razny[6], M. Rodzaj[6], A. Waszczuk-Gajda[7], J. Drozd-Sokolowska[7], A. Galazka[8], A. Swiderska[9], B. Poglodek[10], A. Pluta[10], A. Druzd-Sitek[11], N. Grzasko[12], A. Kopinska[13], A. Pasternak[14], D. Blonska[15], M. Hus[2], A. Dmoszynska[1]

Rydygiera, Cracow, [7]Department of Hematology, Oncology and Internal Medicine, Medical University of Warsaw, [8]Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, [9]Department of Hematology, WSK, Zielona Gora, [10]Department of Oncologic Hematology, SS, Brzozow, [11]Department of Lymphoid Malignancies, Institute of Oncology, Warsaw, [12]Department of Hematology, St. John of Dukla Lublin Region Cancer Center, Lublin, [13]Hematooncology and Bone Marrow Transplantation, Medical University of Silesia, Katowice, [14]Department of Hematology, SPZOZ, MSWiA, Olsztyn, [15]Department of Hematology, Collegium Medicum UMK, Bydgoszcz, Poland

Background: Three drug bortezomib-based regimens are nowadays generally recommended standard induction therapy for transplant-eligible patients with newly diagnosed multiple myeloma (MM). The choice between different regimens depends on drug availability in particular countries, their toxicity profile and local preferences. Observations from routine practice might have though significant clinical importance.
Aims: The aim of this retrospective analysis was to evaluate the efficacy and safety of VTD regimen in newly diagnosed MM patients eligible for HDT/autoSCT in routine clinical practice.
Methods: We collected the clinical data of 169 patients qualified to HDT/autoSCT treated with VTD as an induction regimen in 14 Polish hematology/oncology centers. VTD protocol recommended by Polish Multiple Myeloma Study Group was as follows: bortezomib: 1.3mg/m^2 (days 1,4,8,11), thalidomide: 100 – 200mg a day (days 1-21), dexamethasone 20mg a day (days: 1,2, 4,5, 8,9, 11,12) or 40mg a day (days 1- 4), every 21 days. Patients were included into analysis if ≥1 cycle of VTD was administered. Adverse events (AEs) were graded according to CTCAE v4.0. The analysis involved also the impact of VTD regimen on efficiency of stem cells mobilization as well as high dose therapy/ autologous stem cell transplantation (HDT/autoSCT) procedure.
Results: In the cohort of 169 patients, median age was 59 years (range 36-70). ISS stage 1 was found in 30.8% of patients, ISS 2 and 3 in 20.7% and 45.5%, respectively. Median number of VTD cycles was 5. In 81.6% of patients bortezomib was administered subcutaneously. Thalidomide dose was 100mg a day in 85.1% of patients. Bortezomib dose was reduced in 43 patients (25.4%) with peripheral polyneuropathy as the most common reason (75%). Polyneuropathy was also the most common grade 3/4 adverse event, observed in 20 patients (11.8%) and neutropenia was the most common hematologic toxicity, though it was noted only in 5 patients (3%). Response rate ≥ PR was achieved in 95% of patients, including 5.6% of sCR, 27.1% of CR and 35.1% of VGPR. So far, stem cell mobilization was performed in 110 patients, most commonly used protocols were cyclophosphamide (42.9%) and cytosine arabinoside (36.2%). In 69.3% of patients one apheresis allowed to obtain the number of stem cells sufficient for transplantation. Median yield of CD34+ cells was 11 x 10^6/kg (max 55.7x10^6/kg) that was sufficient for two transplantations in the majority of patients. HDT/autoSCT was performed so far in 89 patients with MEL 200 protocol as conditioning regimen in 77.6% of patients. Median number of transplanted CD34+ cells was 4.4 x 10^6/kg. Median time to reach ANC count >0.5 G/L and PLT count >20 G/L was 11 days and 12 days, respectively. In the evaluation of response 100 days after HDT/autoSCT performed in 81 patients, sCR rate increased from 5.6% to 12.7% and CR from 27.1% to 36.7%.
Summary/Conclusions: VTD regimen allowed allowed to achieve ≥ PR in 95% of patients including ≥ VGPR u 64.8% of patients as compared to 73.5% ≥ PR including 36% of ≥ nCR achieved in patients treated with CTD in our previous study (Dmoszynska *et al.* Leuk Res 2010). In 96% of patients subsequently undergoing stem cell mobilization sufficient numer of CD34+ cells was obtain during first procedure. HDT/autoSCT further increased response rate after VTD induction (≥ CR up to 43.5%, ≥ VGPR up to 83.5%).

E1258

HIGH CUT OFF HEMODIALYSIS FOR RENAL RECOVERY IN PATIENTS WITH MULTIPLE MYELOMA: FIVE YEARS OF EXPERIENCE

A. Berni Wennekers[1,*], M. V. Dourdil Sahun[2], E. Bonafonte Arruga[2], A. Asensio Matas[2], M.P. Martin Azara[1], R. Alvarez Lipe[1], L. Palomera Bernal[2]
[1]Nephrology, [2]Hematology, Hospital Clinico Universitario "Lozano Blesa" Zaragoza, Zaragoza, Spain

Background: Up to 20% of patients with multiple myeloma (MM) present acute kidney injury (AKI) as complication and half of them can even require dialysis. The toxicity of serum free light chains (sFLC) is the main cause of renal damage in MM.
Aims: Demonstrate that rapid and sustained reduction of sFLC levels by combined chemotherapy and high cut-off hemodialysis (HCO-HD) improves renal outcome.
Methods: From July 2011 to July 2016, were performed 21 treatments on 19 patients with MM and serum concentrations of FLCs above 500mg/L who had severe AKI requiring hemodialysis according to KDIGO criteria. The HCO-HD was initiated immediately after establishing hematology diagnosis and simultaneously to bortezomib-based induction chemotherapy. A dialytic protocol was instated based on the Hutchinson scheme: HCO filter of 2.1m^2 (Theralite™ by Gambro®). Initially daily sessions on 6 consecutive days; afterwards, dialysis on alternate days until getting levels of sFLC under 500mg/L or recovering a renal function to avoid dialysis. The duration of every dialysis was 6 hours with low blood flow between 250-300ml/min, and a bath flow of 500 ml/min (ultrapure water). Blood monitoring includes renal function, sFLC, calcium, phosphorus, albumin and ions.
Results: The patients were 12 men and 7 women, aged 60±4 years (37–73 years). 10 patients were diagnosed with lambda FLC MM and 9 with kappa type. A total of 244 sessions were conducted, with an average of 11.6 sessions per patient (range 3-27) In all cases reduction of serum FLCs concentration was successfully achieved. (90% of reduction). At the end of treatment with HCO-HD, the reduction of lambda and kappa FLCs concentrations was 85% and 94%, respectively. The average reduction per dialysis session was 65% for lambda and 60% for kappa. 17 out of the 21 treated cases recovered sufficient renal function to become independent of dialysis (80.9% renal recovery). Renal recovery appears to be sustained over time. There was a significant association between the percentage reduction in serum FLCs concentrations and renal recovery. Our results confirm previous findings on the effectiveness of FLCs reduction by HCO-HD. Until randomized trials yield results, our highest percentage of improve renal outcome with respect to published studies leads us to recommend combined therapy of chemotherapy and HCO-HD in patients with MM and renal failure.
Summary/Conclusions: In dialysis-dependent AKI secondary to MM, combination HCO HD with chemotherapy allows a sustained reduction of FLCs levels, representing an effective therapy in renal recovery.

E1259

IMPACT OF IMMUNOPARESIS IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

L.G. Rodríguez-Lobato[1,*], C. Fernández de Larrea[1], M.T. Cibeira[1], N. Tovar[1], J.I. Aróstegui[2], L. Rosiñol[1], M. Elena[3], J. Yagüe[2], J. Bladé[1]
[1]Department of Haematology, [2]Department of Immunology, [3]Department of Biochemistry, Hospital Clínic, Barcelona, Spain

Background: The presence of immunoparesis (IP) at diagnosis in several plasma cell disorders is a risk factor for progression, associated with an unfavorable outcome with reduced progression-free survival (PFS) and overall survival (OS). However, its impact in light chain (AL) amyloidosis has been evaluated only in few series, and when present it was associated with worst response and survival.
Aims: The aim of this study was to investigate the prognostic impact of IP in patients with newly diagnosed AL amyloidosis at a single institution.
Methods: We reviewed the clinical records of patients with AL amyloidosis diagnosed from January 2006 to December 2016. Sixty-nine patients (32F/37M; median age at diagnosis 62) with available immunoglobulin (Ig) measurements were the final study population. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up was 30.2 months. IP was defined as suppression of all uninvolved Ig below the lower reference value. PFS and OS were calculated from the date of diagnosis.
Results: Forty-three patients (62.3%) were transplant ineligible while 26 (37.7%) underwent an autologous stem cell transplantation (ASCT). The distribution of the monoclonal protein isotype by immunofixation at diagnosis was as follows: light chains only (46.4%), IgG (39.1%), IgA (10.2%) and IgM (4.3%). The predominant light chain isotype was lambda (79.7%). A very good partial response (VGPR) or better was achieved in 53.6% of patients. Three-year OS rate was 64.3%. IP was observed in 27.5% of the patients at diagnosis. Patients with IP had a higher bone marrow plasma cells (BMPC) infiltration (29 *vs.* 9; *P*<0.001). Also a trend towards a higher difference between involved and uninvolved free light chains was observed in the group of patients with IP (360.2 *vs.* 221.7; *P*=0.08). IP was more frequent in those who received an ASCT (57.9% *vs.* 42.1%; *P*=0.03). There were no changes in the frequency of IP comparing at diagnosis *vs.* post-ASCT settings (39.13% *vs.* 34.78%; *P*=0.4). Regarding its prognostic value, IP did not influence survival in the whole series. In the ASCT group, the presence of IP resulted in a significantly shorter PFS (median: 30.2 months *vs.* not reached [NR]; *P*=0.019; Figure 1A) and a trend in OS (62.5 months *vs.* NR; *P*=0.097). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months *vs.* NR; *P*=0.047; Figure 1B), but not significantly different in OS. Multivariate analysis restricted to the population of patients with stage I and II Mayo12, incorporating ASCT, BMPC and IP, indicate that IP retained its independent prognostic factor for worse PFS (HR=12.06; 95% CI, 1.9-75.7; *P*=0.008).

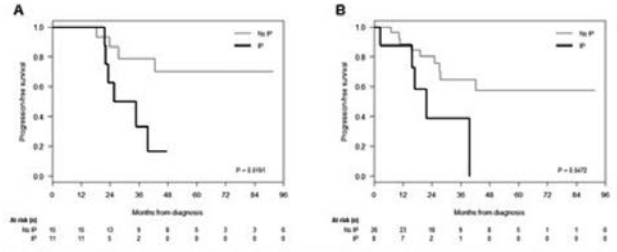


Figure 1. Progression-free survival according to the presence of immunoparesis in the group of patients who received an autologous stem cell transplantation (A), and in the group of patients with stage I and II of the Mayo risk stratification system of 2012 (B).

Figure 1.

Summary/Conclusions: The presence of IP has a negative impact on survival, especially in the sub-group of patients in early stages of the disease. The presence of IP at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients without advanced stage of the Mayo risk stratification system of 2012.

E1260

TREATMENT PATTERNS AND DURATION OF TREATMENT IN JAPANESE MULTIPLE MYELOMA PATIENTS RECEIVING SECOND LINE THERAPY WITH NOVEL AGENTS

G. Jun[1,2,*], I. Mishiro[1], H. Shinzo[1], T. Skacel[3], K. Iwasaki[4], J. Soeda[1]
[1]Japan Medical Affairs, Takeda Pharmaceutical Company Limited, [2]Department of Public Health, Juntendo University School of Medicine, Tokyo, Japan, [3]Global Medical Affairs, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, United States, [4]Milliman, Tokyo, Japan

Background: The introduction of novel agents, such as proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) approved in 2006 and 2010, respectively, and/or autologous stem cell transplantation (SCT) are associated with improved overall survival of 60.6 months in Japanese multiple myeloma (MM) patients (pts) (Ozaki *et al.* Blood Cancer Journal 2015). However, the disease still remains incurable with disease relapse being inevitable after front-line therapy (FLT). Data regarding treatment patterns and duration of treatment (DOT) of Japanese pts with relapsed and refractory (RR) MM in routine clinical practice is limited.
Aims: This retrospective study aims to describe the treatment patterns and DOT of second-line therapy (SLT) with PI- and IMiD-based regimens and to assess factors that influence treatment choice and DOT of SLT in Japanese MM pts.
Methods: This is retrospective cohort study in pts with MM diagnoses with ICD-10-CM (C900) codes between April 2008 and January 2016 in Japan. This study used Japanese health insurance data provided by Medical Data Vision. MM pts receiving SLT were included. Index date was defined as the first observed claim for MM treatment and SLT was defined as switch to another drug combination>60 days or retreatment following a treatment gap of>90 days after starting FLT. Pts with salvage SCT were excluded. Observations were censored at loss to follow up, death or the end of study period. Kaplan-Meier analyses were performed to calculate DOT from the start of SLT. Welch's test was used to test for statistical significance between groups.
Results: Among 585 pts receiving SLT, mean age was 68.8 years of age (yo); 65.3% were ≥65 yo at start of SLT; 54.2% were male. Most pts received lenalidomide (L)-based SLT (35.4%), followed by bortezomib (B)-based regimens (29.4%) and other regimens not containing novel agents (35.2%); Other regimens includes thalidomide, cyclophosphamide, etoposide, melphalan, vincristine, (liposomal) doxorubicin, interferon, panobinostat, single-agent steroid; only 1.2% received B+L combination therapy. L±D and B±D were the most common (35.2% *vs* 21.7%) in SLT. Majority of Japanese pts received B-based regimen in FLT among those receiving L±D and B±D SLT (77.2% *vs* 55.1%). Pts with peripheral neuropathy (PN) and renal insufficiency (RI) prior to SLT were 30.3% and 15.6%, respectively; those with PN were more likely to receive L±D compared to B±D (35.9% *vs* 21.3%, P=0.0047), but those with RI was not independently associated with treatment choice of SLT. Median DOT of L±D was longer than B±D (13.8 *vs* 6.9 months, P=0.0001); DOT was similar for those without a front-line SCT and receiving B±D FLT in both regimens (11.9 *vs* 11.9 months). PN and RI prior to SLT and age have not shortened the DOT in SLT. Additionally, 35.4% experienced PN during SLT among pts receiving L±D and B±D in SLT but there was no statistical significant difference of DOT between pts with and without PN. Median daily dose of L was 12.0mg; there was no significant difference of DOT between pts received at least and less than 12.0mg.

Table 1.

Table 1. Patient Characteristics and DOT by SLT Regimen

Type of SLT Regimen	L ± D N=206	B ± D N=127	p-value
Median Age (yo)	67	71	0.119
Front-line SCT (%)	32.5	14.2	0.0002
PN prior to SLT (%)	35.9	21.3	0.0047
RI prior to SLT (%)	16.0	15.0	0.7960
DOT (mos)	13.8	6.9	0.0001
DOT for pts <65 (mos)	11.3	5.5	0.0030
DOT for pts ≥65 (mos)	17.0	6.9	0.0001

Summary/Conclusions: Among pts in SLT, 65% of Japanese pts obtained L- and B-based regimens. This observation is similar to the United States (Romanus *et al.* EHA 2016) and Europe (Raab *et al.* EHA 2015). Majority of pts did not receive triplet-based regimen. Pts experienced PN in FLT were more likely to initiate L-based therapy in SLT and regimen type in SLT was correlated with DOT. Future research is needed to better understand treatment changes in routine clinical practice and the impact on pts' outcomes, especially, after integration of novel agent-based triplet combinations as new standards of care in RRMM in Japan.

ROLE OF HEAVY/LIGHT CHAIN RATIO IN MYELOMA PATIENTS ACHIEVING COMPLETE RESPONSE AFTER FIRST LINE THERAPY

F. D'auria[1,*], F. La Rocca[1], V. Simeon[1], T. Statuto[1], G. Pietrantuono[1],

G. D'Arena[1], O. Villani[1], G. Mansueto[1], A. Patriarca[1], C. Bitetti[1], E. Seneca[1], A. Traficante[1], P. Musto[1]
[1]IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture (PZ), Italy

Background: Polyclonal antibodies against the conformational epitopes between the heavy and light chains (HLC) of immunoglobulin (Ig) have been recently introduced as diagnostic tool in multiple myeloma (MM) and other monoclonal gammopathies. They separately identify the two different light chain types of each Ig, allowing the quantification of the monoclonal component. HLC and HLC ratios may be particularly useful for monitoring the presence of monoclonal component in oligo-secretory MM or when it migrates in the β region, as frequently observed in IgA MM. The International Myeloma Working Group (IMWG) has published in 2016 new consensus criteria for assessing response and minimal residual disease (MRD) in MM, outlining the potential role of HLC assay in this setting and the need of its further investigation, particularly in patients achieving complete response (CR) after treatment.
Aims: We conducted a single center, prospective study of HLC ratio, in comparison with free light chain (FLC) ratio, for the evaluation of MRD and its prognostic role in MM patients achieving CR after first line treatments including novel agents.
Methods: Twenty-five consecutive patients were evaluated. Mean age was 63 years (range 43-82), fourteen patients were males. Ig isotype was IgG or IgA in 14 and 11 patients, respectively, with 20 patients showing kappa and 5 lambda light chains. According to International Staging System, seven patients had stage 1, ten stage 2 and eight stage 3. Fourteen patients not eligible to autologous stem cell transplantation (AuSCT) received a bortezomib-based treatment, mainly constituted by bortezomib, melphalan and prednisone combination (VMP), while eleven patients underwent AuSCT after induction therapy with bortezomib, thalidomide and dexamethasone (VTD). With a median follow-up of 52 months (range 21-92), overall survival (OS) of the entire cohort was 61 months (95% CI 52-80) and progression-free survival (PFS) was 26 months (95% CI 12-38). Ig HLC pairs (IgGk/IgGλ and IgAk/IgAλ) and FLC were analyzed on serum samples at diagnosis and at the time of immunofixation negative CR (according to 2006 IMWG criteria), using Hevylite and Freelite commercial kits, respectively, on a SPAplus analyzer (Binding Site); IgGk/IgGλ, IgAk/IgAλ and k/λ ratios were then calculated.
Results: At CR time, we found seven (28%) samples still showing abnormal HLC ratio and fourteen samples (56%) with abnormal FLC ratio. Discrepancies between the two assays occurred in 11 patients. FLC assay normalization in CR was significantly associated with better PFS (43 months, 95% CI 14-45) respect to patients with persistent abnormal FLC ratio (12 months, 95% CI 9-35, p=0,049). In contrast, normalization of HLC ratio had no impact on PFS (26 months, 95% CI 10-38, *vs* 20 months, 95% CI 10-34, p=0,51), even selecting IgA MM. Notably, in 9 patients, the negative effect of abnormal FLC ratio at CR on PFS was not mitigated by concomitant normalization of HLC ratio (19 months, 95% CI 4-35; p=0,022). Neither FLC, nor HLC affected OS. There were no differences between patients who received AuSCT and those who did not.
Summary/Conclusions: To the best of our knowledge, this is the first study to analyze HLC ratios exclusively in MM patients in CR. While our preliminary data confirm the prognostic usefulness of FLC in this setting, currently they do not support a role for HLC as putative biomarker of MRD.

Background: Emerging resistance to modern antimyeloma agents such as proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) remains the main clinical problem in managing multiple myeloma (MM). Daratumumab, a first-in-class anti-CD38 monoclonal antibody, has been recently approved in Europe as a monotherapy for patients (pts) with relapsed and refractory multiple myeloma (RRMM), whose prior therapy included a PI and an IMiD and whose disease had progressed during this time; based on the SIRIUS clinical trial outcome (Lonial *et al.* Lancet 2016). Nevertheless to optimize daratumumab use in clinical practice, more data on its "real life" activity and safety are still required.
Aims: This observational study of the Polish Myeloma Group (PMG) was aimed to prospectively evaluate the efficacy and toxicity of daratumumab monotherapy in RRMM pts treated within the daratumumab compassionate use named patient program in Poland (DaraCUP).
Methods: Patients were eligible for DaraCUP if they met all the following criteria a) confirmed diagnosis of RRMM, b) relapse after a minimum of 3 prior lines of therapy (including PI and IMiD) or were double refractory to PI and IMiD, c) had a ECOG performance status score 2 or lower. Data on treatment outcomes and complications were anonymously collected using electronic CRFs. The IMWG response criteria were applied.
Results: In total 30 patients were qualified to DaraCUP in Poland and all were enrolled to the PMG observational study. At the time of writing this report, 26 pts (87%) had received at least one dose of daratumumab and were included in the safety analysis, while 22 pts (73%) had received at least 2 cycles of daratumumab and were included in the preliminary efficacy analysis. Baseline pts characteristics are reported in Table 1. Pts were heavily pretreated, with a median of 4 prior lines of therapy (range, 2-10). Ten pts (38.5%) were double refractory to both PI and IMiD while 15 pts (58%) were refractory to the last line of previous therapy. Median time since initial diagnosis to start of treatment with daratumumab was 3.9 years (range, 1.4-12.2 years). At the time of analysis, the median follow-up time within the study was 5.1 months (range, 0-8 months) and median daratumumab treatment duration was 4.4 months (range, 0-8 months). Sixteen pts (61.5%) remain on treatment, while ten pts (38.5%) discontinued therapy as a result of disease progression (n=7) and adverse events (AEs) (n=3). Overall response rate (PR or better) was 31.8% including one (4.5%) CR and two (9%) VGPR (Table 1). Stable disease was reported in 11 (50%) pts. The median PFS and OS had not been reached. During the time of observation three deaths were recorded due to disease progression. Regarding daratumumab toxicity, grade 3 or 4 non-haematological toxicities occurred in 8 pts (30.7%) and included: infusion-related reactions (n=2), pneumonia (n=2), other infections (n=2), mandible inflammation (n=1), dyspnoea (n=1). The most common haematological toxicities of any grade were anaemia (n=8; 30.7%) and neutropenia (n=6; 23.1%) while thrombocytopenia occurred in 3 pts; 11.5%. Grade 3 or 4 anaemia and neutropenia were found in 3 (11.5%) and 2 (7.7%) pts, respectively. Updated results will be presented at the meeting.

>60 ml/min	15 (58%)	60 (57%)	Last line of previous therapy	15 (58%)	103 (97%)
30 to 60 ml/min	11 (42%)	42 (40%)	Both proteasome inhibitor and immunomodulatory drug	10 (38%)	101 (95%)
<30 ml/min	0	4 (4%)			
Time since initial diagnosis (years; median, range)	3.9 (1.4-12.2)	4.8 (1.1-23.8)	Response		
			sCR	0	3 (2.8%)
			CR	1 (4.5%)	0
			VGPR	2 (9%)	10 (9.4%)
			PR	4 (18%)	19 (17%)
			SD	11 (50%)	46 (43.4%)
			PD	4 (18%)	18 (17%)

Summary/Conclusions: In this first real-world analysis we confirm that daratumumab monotherapy is able to induce response in one third of highly pretreated and double refractory RRMM patients. Regarding safety, in contrast to the SIRIUS trial where no treatment discontinuations due to AEs occured, 3/26 pts (11%) treated with daratumumab in clinical practice had their therapy interrupted due to complications.

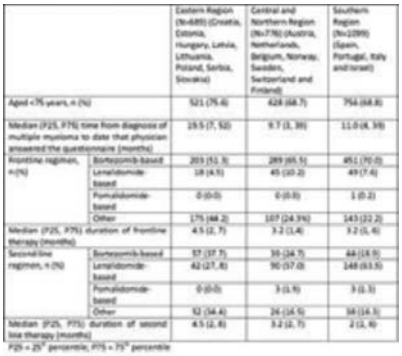
E1263

REAL-WORLD TREATMENT PATTERNS AND PATIENTS CHARACTERISTICS IN MULTIPLE MYELOMA ACROSS EUROPE

A. Fernandez[1,*], A. Zomas[1], E. Papakostas[1], T. Do[1], M. Russo[2], R. D'Ambrosio[1], G. Schneidewind[1]
[1]EUCAN Medical Affairs, [2]Global Market Access, Takeda, CH-8152 Glattpark-Opfikon (Zurich), Switzerland

Background: Multiple myeloma (MM) is the second most common haematological malignancy after non-Hodgkin lymphomas, accounting for 13% of blood malignancies and 1% of all cancers[1]. The medical management of multiple myeloma has changed over the years and is influenced by multiple factors (e.g., evidence from clinical trials, drug approval status, level of drug reimbursement, guidelines), which vary across Europe. Information describing how patients are managed in the real world is needed.
Aims: The aim of this analysis was to investigate real-world treatment patterns and patient characteristics in MM across Europe.
Methods: Physicians in Europe were requested to answer a series of questions on patient characteristics and treatment regimens of the last eight patients that they had treated during the month prior to answering the questionnaire, according to their patients' medical charts. The questionnaire was conducted between January and June 2016. Data on 2564 patients with MM were available and are presented here. Countries were grouped into regions according to similar health care systems: Spain, Portugal, Italy and Israel (Southern Region, SR, n=1099); Austria, Netherlands, Belgium, Norway, Sweden, Switzerland and Finland (Central and Northern Region, CNR, n=776); Croatia, Estonia, Hungary, Latvia, Lithuania, Poland, Serbia, Slovakia (Eastern Region, ER, n=689). Analyses were descriptive
Results: Patient characteristics were generally similar across regions, with the majority being <75 years old (69-76%), receiving frontline therapy at study inclusion (57-58%), and being ineligible for autologous stem cell transplant (ASCT) (53-59%). The median time from MM diagnosis to the time that the physician answered the questionnaire was higher in ER (19.5 months) than other regions (9.7-11 months) (Table). The majority of frontline regimens contained bortezomib although this was lower in ER (51%) than other regions (66-70%). The median duration of frontline therapy was longer in ER (4.5 months) than other regions (3.2 months). This difference was mainly driven by ASCT eligible patients having longer duration of therapy in ER (4.5 months) than other regions (2.2 months). The number of bortezomib injections in frontline therapy, however, was higher in SR and CNR (both 24) than in ER (18). The majority of second line regimens contained lenalidomide (57-64%) in all regions except ER, where bortezomib-based regimens were most frequent (38%). The median duration of second line therapy was shorter in SR and CNR than in ER (Table). Moreover, for second line therapy, ASCT-eligible patients had shorter duration of therapy in ER and SR (3.2 months) than in CNR regions (4.5 months). The majority of later-line (3+) regimens were based on therapies that did not include bortezomib, lenalidomide or pomalidomide for all regions (57-67%) with the exception of SR where pomalidomide (29.4%), lenalidomide (12.6%) and bortezomib (14%) were the preferred options. In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Table 1.



Summary/Conclusions: In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

E1264

FRAILTY AND MORTALITY IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA

N. Schutz[1,*], M. Smietniansky[1], D. Fantl[1], V. Otero[1]
[1]Medicina Interna - Hematología, Hospital Italiano de Buenos Aires, CABA, Argentina

Background: Worldwide, life expectancy continues to rise. The treatment of elderly people with cancer poses special challenges that should be better addressed. Frailty is a geriatric syndrome associated with reduced functional reserve, impairment in multiple physiological systems, and reduced ability to regain physiological homeostasis.
Aims: To evaluate the impact of the level of frailty on early death and overall survival of elderly patients with multiple myeloma.
Methods: Retrospective study of a cohort of 150 patients older than 65 years with a recent diagnosis of multiple myeloma from January 2006 to December 2012. Patients were treated with IMIDs, alkylating or bortezomib based chemotherapy based on physician preference blind to the geriatric assessment. A check list for frailty burden measurement was used based on Edmonton frailty score and included: cognitive impairment, depressive disorder, polypharmacy, urinary incontinence, functional impairment, gait disturbance or falls, low weight or weight loss and previous hospitalization. Level of frailty was scored as the sum of each area involved. Record of all the variables were obtained from a retrospective review of the centralized and computerized medical records by a hematologist and geriatrician, using predefined standardized criteria. Patients were classified as fit (0-1 frailty criteria), vulnerable (2-3 criteria) or frail (≥ 4 criteria). OS and PFS were estimated using the Kaplan Meier method using Stata13 program Group differences according to frailty were investigated using the Cox proportional hazard model accounting for ISS, age, Charlson comorbidity index and treatment.
Results: From the 150 patients evaluated, 124 patients were included in the study. The median age was 77 years (range 65-98). Thirty one percent of the patients were older than 80 years, 51% were female. The median Charlson Comorbidity index was 2 (range 0-7), 28% had renal failure and 40% of the patients presented with Myeloma ISS 3. Sixty five percent of patients met at least one frailty criteria and 31% of patients were considered frail. The most common findings were polypharmacy, gait and functional impairment. Most patients were treated with IMIDs (47%); alkylating agents (33%) or borteomib (14%) based chemotherapy. There was no difference in treatment according to frailty group (p=0.38). The median overall survival time was 75 months (95% CI 53-110), 39 months (95% CI 19-64) and 17 months (95% CI 5-37) for fit, vulnerable and frail patients respectively (log rank p 0,0002). Frailty was specially associated with early death [OR 8,2 (95% CI 1,9-34) p=0.0007]. In the multivariate analysis a higher risk of death was observed related to age [HR 1,07 (95% CI 1,02-1,12) p 0,002], number of frailty criteria [HR 1,13 (95% CI 1 – 1,3) p 0,05] and ISS [HR 2,6 (95% CI 1,8 -3,8) p 0,001]. The frailty criteria independently associated with death were incontinence polypharmacy and previous hospital admissions. Frailty was specially associated with early death [OR 8,2 (95% CI 1,9-34) p=0.0007].

Table 1.

Table 2: Univariate and Multivariate Cox Regression Analysis

Variable	Univariate Analysis		Multivariate Analysis	
	HR (95% CI)	P value	HR (95% CI)	P value
Age years	1.09 (1.05-1.3)	<0.001	1.07 (1.02-1.12)	0.002
Charlson Comorbidity index	1.2 (1.05-1.3)	0.005	1-04 (0.88-0.23)	0.61
Number of Frailty criteria	1,27 (1.14-1.43)	<0.001	1.13 (1-1.3)	0.05
ISS	2.6 (1.9 -3.9)	<0.001	2.6 (1.8 – 3.8)	0.001
Presence of Renal Failure	1.6 (0.99-2.6)	0,054		
Tipo de QT				
Alquilantes	1.38 (0.75-2.53)	0,29		
IMIDs	1.63 (0.89-2.93)	0,11		
Bortezomib	1.23 (0.45-3.37)	0,68		

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.

E1265

PROGNOSIS OF AL AMYLOIDOSIS WITH KIDNEY INJURY

A. Talbot[1,*], X. Belenfant[2]
[1]Immulogy, hopital Saint Louis, paris, [2]Nepgrology, chiag, montreuil, France

Background: AL amyloidosis is a rare disease related to excessive and uncontrolled secretion of monoclonal light chains. The consequence of this proliferation is an alteration of the affected organs due to deposition of free light chains. Despite therapeutic advances in recent years based, among others, on the finding of French studies, the prognosis of this disease remains poor in particular for patients with cardiac disease. Kidney involvement is also frequently observed at diagnosis in the form of a classical nephrotic syndrome, but at present the prognosis of chronic renal failure in this context is unknown.
Aims: The study was interested in the prognosis of AL amyloidosis associated with endstage renal disease on dialysis in the era of treatment with bortezomib.
Methods: A total of 133 patients (61 from Ile-de-France region register and 72 from reference center) were analyzed.
Results: A total of 133 patients (61 from Ile-de-France region register and 72 from reference center) were analyzed. Median survival was 66.7 months compared to 70.6 months for patients without dialysis (p=0.65). Within the group

of patients on dialysis, there is no significant difference between those receiving or not bortezomib. Median survival before 2008 was 54.82 months and rose to 82.30 months for patients treated after this date (p=0.95). Age (HR: 0.2819, CI 0.1375 to 0.5782), heart disease (HR: 0.3746, CI 0.1724 to 0.8141) and serum albumin (HR: 2.500 CI: 1.077 to 5.803) were identified as prognostic factors. Transplantation is a viable treatment option for good responders.
Summary/Conclusions: Prognosis of AL amyloidosis in dialysis is heterogeneous. Prognostic scoring integrating clinical biological data could identify the patient who may benefit the most dialysis. This results need to be matched by sex and age with non-dialysis and dialysis for another cause.

Background: The combination of lenalidomide/dexamethasone (LenDex) is an established treatment for relapsed/refractory Multiple Myeloma (MM) patients; however, apart from clinical trials, there is limited data for the efficacy of this combination as 2nd line treatment. Furthermore, the efficacy of LenDex when administered before evident clinical manifestations, namely in the case of biochemical relapse as compared to clinical relapse, has not yet been assessed.
Aims: In the current study, we evaluated response rates and progression-free survival (PFS) in patients treated with LenDex in 2nd line and we compared survival parameters for patients treated with LenDex at biochemical relapse *vs* those treated at clinical relapse.
Methods: Medical files of 207 patients with MM diagnosed between 2000-2013 in 18 Greek centers and treated with LenDex as 2nd line treatment from January 1st 2009, up to March 1st 2014, were retrospectively studied. Overall response and PFS were evaluated for all patients. Additionally, PFS was compared in patients treated at either biochemical relapse (group A) or at clinical relapse (group B). The prognostic significance of biochemical relapse adjusted with important patients' characteristics was also evaluated. Classical methods were used for statistical analysis.
Results: Two hundred and seven patient files were recorded and analyzed (M/F: 112/95, median age: 67.2y, range 31-91y, IgG: 115, IgA: 55, Light chain: 22, non-sectretory: 2, IgD: 5, IgM: 1, unknown: 7, ISS I: 54, ISS II: 74, ISS III: 77, high risk: 13%, standard risk: 87%). First line treatment included bortezomib-based regimens (63.3%), immunomodulatory drug-based combinations (34.8%) and chemotherapy (40.1%); 25% of patients underwent autologous stem cell transplantation; 2nd line treatment with LenDex was administered at biochemical relapse in 67.5% (95% CI: 61.1% >73.9%) of patients and at clinical relapse in 32.5% (95% CI: 26.1-38.9) of patients. The overall response rate (ORR) was 73.4%; 23.7% of patients achieved very good partial response (VGPR) and 17.8% complete response (CR). The number of patients that achieved at least VGPR did not differ between the 2 groups (p>0.05). The median time to best response was 6.7 months (range 0.6- 51.9). After a median follow-up of 52.8 months, 112 (54.1%) patients are alive and 95 (45.9%) patients are deceased; 131 patients (63.3%) have relapsed (biochemical relapse: 66.4%, clinical relapse: 33.6%). Median PFS and PFS rate at 12 months was 19.2 months (95% CI: 15.6-25.2) and 67.6% respectively. The median PFS was 24 months (95% CI: 18.0-34.8) for patients in group A *vs* 13.2 months (95% CI: 8.4-19.2) for patients in group B (HR: 0.63, p=0.006). When adjusted for important prognostic patients' characteristics (ISS, age, β2 microglobulin, and LDH), biochemical relapse maintained its prognostic significance for PFS (p<0.05).
Summary/Conclusions: Our data confirm that Lendex combination as 2nd line treatment leads to high overall response rates and prolonged PFS. Additionally, we have shown for the first time in routine clinical practice that MM patients who receive 2nd line therapy with LenDex at biochemical relapse have a significantly longer median PFS compared to patients treated at clinical relapse, underlining the importance of potentially starting treatment before evident clinical manifestations at the first relapse.

FDG-PET IN MULTIPLE MYELOMA: DUAL TIME POINT FDG UPTAKE IN FOCAL LESIONS CORRELATE TO RESPONSE TO CHEMOTHERAPY

B. Oestergaard[1,*], R. Taghvaei[2], W.Y. Raynor[2], M.Z. Zirakchian[2], A. Nielsen[3], J.T. Asmussen[4], P. Holdgaard[5], T. Plesner[6], A. Alavi[2], N. Abildgaard[1], P.F. Hølund-Carlsen[3]
[1]Hematology, Odense University Hospital, Odense, Denmark, [2]Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, [3]Nuclear Medicine, [4]Radiology, Odense University Hospital, Odense, [5]Nuclear Medicine, [6]Hematology, Vejle Hospital, Vejle, Denmark

Background: Dual Time Point (DTP) ^{18}F-FDG PET imaging has been shown to be useful in differentiating malignant from benign lesions in that increasing uptake from 1 to 3 hours is a characteristic feature of malignancy in contrast to inflammation.
Aims: The aim of this study was to evaluate the predictive role of DTP ^{18}F-FDG PET/CT imaging in assessing response to chemotherapy in multiple myeloma (MM).
Methods: 23 patients with MM (21 male, aged 53-75 years) underwent ^{18}F-FDG PET/CT in a prospective study (NCT02187731) before start of treatment and two months after high dose chemotherapy with stem cell support. All scans were performed at 60 and 180 minutes after tracer injection at Odense University Hospital and Vejle Hospital. Thirteen patients with ≥ 3 focal lesions of at least 10 mm were selected for analysis. Images were analyzed using an adaptive thresholding algorithm (ROVER software; ABX GmbH, Radeberg, Germany). Focal malignant lesions were localized in pre-treatment scans; maximum standard uptake value (SUVmax) and mean SUV (SUVmean) and partial volume corrected SUVmean (pvcSUVmean) were obtained for each lesion. Lesional response to chemotherapy was classified as complete or partial in the post-treatment scan. A complete response was defined as a complete resolution of the lesion in the post-treatment scan. Lesions with partial response were present in the post-treatment scan. All statistical analyzes were done in SPSS 24 using repeated measurements-ANOVA.
Results: Three-five focal lesions were evaluated in each patient. In the pre-treatment PET studies, the increase in SUVmean from 1 to 3 hours was significantly higher for lesions with partial response compared to those with complete response (27.7% *vs* 11.4%; P=0.050). Additionally, the increase in pvcSUVmean was more significant than the increase in SUVmean (+42.23% *vs* +12.0%; P=0.003). The increase in SUVmax of delayed scans was not significant (P =0.082).
Summary/Conclusions: These preliminary data show that a more significant increase of FDG uptake in delayed scans of DTP PET before treatment correlates with a poor response of focal malignant lesions to chemotherapy in MM. The increase in pvcSUVmean is a better index than those of SUVmean and SUVmax for this purpose.

E1268

UNDERSTANDING THE CONTRIBUTE OF THE NOTCH PATHWAY IN MULTIPLE MYELOMA BONE MARROW NICHE: A FOCUS ON EXTRACELLULAR VESICLES-MEDIATED COMMUNICATION

M. Colombo[1,*], F. Baccianti[1], L. Cantone[2], A. Moschini[1], N. Platonova[3], S. Garavelli[1], M.T. Palano[1], R. Adami[1], A. Neri[3], V. Bollati[2], R. Chiaramonte[1]
[1]Dept. of Health Sciences, [2]Dept. of Clinical Sciences and community health, [3]Dept. of Oncology and Hemato-Oncology, Università degli Studi di Milano, Milano, Italy

Background: Multiple myeloma (MM) is an incurable cancer stemming from malignant plasma cells. MM is characterized by a strong tropism to the bone marrow (BM), where tumor cells accumulate and establish complex interactions with the normal stroma, which in turn promotes tumour survival, drug resistance and the development of bone disease. The Notch oncogenic pathway provides a key contribute to the ability of MM cells to shape the BM niche, affecting both MM cell biology and the interplay with the surrounding normal cells. Recently, extracellular vesicles (EVs) have been reported as novel mediators in creating a supportive milieu for MM. Here we investigate the role of the activated Notch signaling in EV-mediated cross-talk.
Aims: The aim of this work was to further elucidate the role played by the Notch pathway in the shaping of the BM microenvironment to provide a supportive milieu for MM cells, with a focus on the contribute of EVs to the crosstalk between MM cells and the BM stromal cells.

Methods: We established two MM cell lines stably retaining the doxycycline-inducible pTRIPZ vector containing anti-Jagged1 and Jagged2 shRNAs and a BM mesenchymal stromal cell (BMSC) line expressing shRNAs for Notch1 and Notch2. EVs were isolated by ultracentrifugation and used for functional assays and molecular analysis. qPCR was performed using SYBR Green. Apoptosis analysis was performed by flow cytometry; evaluation of protein expression was achieved by flow cytometry or western blot.
Results: We present evidences that EVs play a crucial role in the dysregulated interactions of MM cells with the BM microenvironment and that Notch regulates their release. Indeed, BMSCs knockdown for Notch1/2 results in a decrease in EVs release and reduce their ability to induce Bortezomib resistance in MM cells and to stimulate their migration. On the other side, MM-derived EVs are able to increase the production of pro-tumor factors by BMSCs (*i.e.* SDF1α), promoting their ablity to boost tumor growth; interestingly, this effect is lost when EVs are isolated from MM cells where the Notch pathway was inhibited. Finally, EVs released by co-cultures of BMSCs and MM cells where the Notch pathway is blocked display a reduced ability to increase osteoclastogenesis compared with EVs from the control culture. This is particularly relevant due to the crucial role played by bone disease in MM progression.
Summary/Conclusions: These new insights in the pathophysiology of the de-arranged BM niche represent the rationale for a Notch-directerd therapy aiming to uncouple the crosstalk of MM with the surrounding microenvironment by inhibiting Notch signaling.

E1269

THE USE OF CARFILZOMIB AND BORTEZOMIB IN ROUTINE CLINICAL PRACTICE: RESULTS FROM PREAMBLE, AN ONGOING, OBSERVATIONAL COHORT STUDY IN MULTIPLE MYELOMA

B. Durie[1,*], G. Cook[2], H. Goldschmidt[3], D. Kuter[4], T. Zyczynski[5], S. Popov[6], M. Gooriah[5], C. Davis[5], R. Vij[7]
[1]Cedars-Sinai Medical Center, Los Angeles, United States, [2]University of Leeds, Leeds, United Kingdom, [3]Heidelberg University Hospital, Heidelberg, Germany, [4]Massachusetts General Hospital Cancer Center, Boston, [5]Bristol-Myers Squibb, Lawrenceville, United States, [6]Parexel, St Petersburg, Russian Federation, [7]Washington University School of Medicine, St Louis, United States

Background: Multiple myeloma (MM) remains largely incurable despite improvements in clinical outcomes following the approval of immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) (Rajkumar et al 2010). Previous findings from PREAMBLE indicated shorter median duration of therapy (DoT) with PIs and IMiDs (5 and 9 mo, respectively; Palumbo et al 2016) *vs* clinical trials (Stewart et al 2014). Understanding real-world use of therapies for relapsed/refractory (RR) MM is important to determine their position in the treatment paradigm.
Aims: In this subsequent PREAMBLE analysis, treatment patterns in patients (pts) with RRMM receiving bortezomib (bort) and carfilzomib (carf) were evaluated to better understand the use of PIs in routine clinical practice.
Methods: PREAMBLE (NCT01838512) is an ongoing, observational, international cohort study exploring real-world treatment patterns and outcomes in pts with MM. Eligible pts were aged ≥18 yrs with diagnosis of RRMM, ≥1 prior therapy and initiated treatment (index therapy) with an IMiD, PI or IMiD+PI within 90 days before to 30 days after study enrollment. Treatment patterns, DoT and time to next treatment (TTNT; for pts who switched or died) were assessed. Informed consent was obtained for all pts.
Results: At data cut-off (Sept 1, 2016), data were available for 924 pts, of which 326 (35%) pts had bort-based index therapy and 86 pts (9%) received carf-based index therapy (63/72 [88%] were enrolled in North America). The most common bort-based combination was bort + dexamethasone (dex; n=99, 30%). The most common carf-based therapies were carf alone (n=40, 47%), followed by carf+dex (n=21, 24%). The most widely used bort dose per 21 days for any bort-based therapy was ≤4.0mg/m^2 (98/151; 65%). The most common carf dose per 28 days received for any carf-based therapy was ≤120mg/m^2 (28/55; 51%). Switch from carf-based index therapy occurred after a median (Q1, Q3) DoT of 3.4 (1.9, 9.5) mo (n=34); most pts switched to pomalidomide (pom)-based regimens (23/34; 68%). Switch rates increased from 17% at 3 mo to 54% at 15 mo, and then to 57% at 24 mo. Median (Q1, Q3) TTNT from index therapy was 5.6 (2.3, 9.0) mo (n=53). Median (Q1, Q3) DoT (n=113) and TTNT (n=173) for bort-based index therapy was 4.5 (2.4, 7.1) and 7.0 (3.7, 12.3) mo, respectively; most pts switched to lenalidomide (43/113; 38%) or pom (33/113; 29%). Switch rates increased from 10% at 3 mo to 57% at 33 mo. Dose reductions on carf-based therapies (6/86; 7%) were mostly determined by clinical decision (67%), whereas for bort+dex (24/99; 24%) adverse events (AEs) were the main reason (63%). Discontinuation/switching from carf-based index therapy was reported for 80% (69/86) of pts, driven mainly by disease progression (39%) and AEs (14%). Similarly, disease progression (27%) and AEs (21%) were also the main reasons for pts discontinuation/switching from bort+dex therapy (84/99; 85%). AEs were reported for 45% (39/86) of pts with carf-based index therapy, most commonly fatigue (12%) and anemia (9%); 70% (69/99) of pts receiving bort+dex had AEs, most commonly thrombocytopenia and diarrhea (each 14%).
Summary/Conclusions: Treatment duration observed for PIs in the real-world clinical practice setting was shorter than reported in clinical trials. As patient enrollment and follow-up continues for PREAMBLE, additional analyses will be conducted to evaluate the impact of these patterns on efficacy outcomes.
Study funding: BMS.

E1270

ROLE OF SERUM FREE LIGHT CHAIN *VS* BENCE JONES MEASUREMENT IN LIGHT CHAIN MULTIPLE MYELOMA (LCMM) AT DIAGNOSIS, DURING TREATMENT AND FOLLOW-UP FOR RESPONSE EVALUATION AND RELAPSE DETECTION

M. Staderini[1,*], M. Berardi[2], A. Caldini[2], C. Nozzoli[3], E. Antonioli[1], A. Bosi[1]
[1]Hematology Department, [2]Azienda Ospedaliero-Universitaria Careggi, Florence, Italy, [3]BMT Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background: According to IMWG recommendations for response assessment in multiple myeloma (MM), serum free light chain (sFLC) measurement should be used to define a "stringent" complete response in symptomatic MM and, only in cases when Bence Jones protein (BJP) is deemed as not quantifiable (<200mg/24h), in light chain multiple myeloma (LCMM). However, data are available suggesting that sFLC could be a more sensitive tool than BJP for minimal residual disease assessment and an earlier indicator of progressive disease (PD). BJP measurement requires to perform both urinary electrophoresis and immunofixation, it is time-consuming for tecnicians and could be limited by poor patient compliance.
Aims: Aim of our study was to retrospectively compare sFLC and BJP results in LCMM patients (pts) at diagnosis, during treatment and follow-up.
Methods: Serum and urine samples were collected from pts affected with plasma cell dyscrasia referring to the Azienda Ospedaliero-Universitaria Careggi between 1st February 2012 and 31 December 2013. Serum and urine protein electrophoresis was performed using Capillarys II, serum and urine immunofixation using Hydrasys II (both from Sebia), sFLC were measured on Immage 800 nephelometer (Beckman Coulter) using Freelite reagents (The Binding Site).
Results: We analized samples from 387 pts having positive serum and/or positive urinary immunofixation and/or abnormal sFLC ratio. Among them, 43 symptomatic LCMM pts were identified having both sFLC and BJP measurement at baseline (at MM diagnosis or first relapse). Serum and urine lab tests results were evaluated at baseline, monthly during therapy and every 3 months during follow-up. Median duration of laboratory monitoring for the whole group was 42 months (range 3-120). Autologous stem cell transplantation was performed in 30% of pts previously treated with proteasome inhibitors (81%) and/or immunomodulating agents (40%) or chemotherapy (9%). sFLC or BJP were not available in 10% of 872 pair of samples from 43 pts. In 10% of cases (68/696 pair of samples) sFLC ratio was abnormal with increased involved FLC without any detectable BJP (FLCr+;iFLC+;BJP-); the opposite (FLCr-;iFLC-;BJP+) occurred in 1% of cases (8/696 pair of samples). Renal failure was found in 9% *vs* 13% of discrepant cases. At baseline, of the 43 LCMM pts, 6 had "measurable disease" only by sFLC due to BJP<200mg/24h and were therefore considered not evaluable for response assessment. Median time to BOR was 3 months by both sFLC and BJP (range FLC: 1-11 mesi; range BJP: 1-10 mesi). Among the remaining 37 pts evaluable for best overall response, 6/37 had complete response according to BJP but not to sFLC; interestingly 5/6 progressed after 2-8 months. Twenty-one pts progressed during follow-up: PD was detected only by sFLC in 4, only by BJP in 1. Both tests were able to detect PD in 16 pts: at the same time in 5, with sFLC-PD occurring earlier in 7 and BJP-PD occurring earlier in 4 pts.
Summary/Conclusions: Both sFLC and BJP measurement are useful in LCMM pts for disease monitoring, however, sFLC assessment appears to be more sensitive in MRD and early relapse identification. These data suggest that BJP could be substituted by sFLC assessment in LCMM. In our series only 1 case showed BJP-PD according to IMWG occurring earlier than sFLC-PD but was considered not clinically significant. On the contrary 5 pts in BJP-CR clinically progressed within few months without having reached FLC-CR. Limits of our study are a small number of pts, inhomogeneous duration of therapy and follow-up and retrospective analysis.

E1271

SUPPRESSION OF THE NON-MONOCLONAL PAIR AS NEW BIOMARKER OF POOR PROGNOSIS IN MULTIPLE MYELOMA PATIENTS AT DIAGNOSIS AND AFTER AUTOLOGOUS STEM CELL TRANSPLANT

J.L. García De Veas Silva[1,*], M.D.S. López Velez[1], C. Bermudo Guitarte[2], R. Rios Tamayo[3], M. Jurado Chacón[3], T. De Haro Muñoz[1]
[1]Department of Laboratory Medicine, Complejo Hospitalario Universitario de Granada, Granada, [2]Department of Clinical Biochemistry, Hospital Universitario Virgen Macarena, Sevilla, [3]Department of Hematology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: The outcome for patients with Multiple Myeloma (MM) is highly

variable. Understanding the prognosis for a particular patient can help when selecting the intensity of treatment to be used and the frequency of reviews. The quantification of heavy/light chains pairs by the immunoassay Hevylite (HLC) allows us a precise measurement of monoclonal and non-monoclonal immunoglobulins of the same isotype.

Aims: The aim of the study is to evaluate i) the impact of the "HLC ratio" defined as monoclonal immunoglobulin over isotype matched non-monoclonal immunoglobulin (involved/uninvolved HLC ratio or i/u HLC ratio), ii) the suppression on non-monoclonal pair denominated "HLC-matched pair suppression" and III) the effect of "systemic immunoparesis" at diagnosis and at +100 days after autologous stem cell transplant (ASCT).

Methods: 85 patients (50 Male:35 Female) with a median age of 70 years (56-78) were followed (35 IgGK, 18 IgGL, 17 IgAK and 15 IgAL). The median follow-up of the patients was 19 (5-30) months. Sixteen patients (18%) presented ISS stage I, 15 (28%) with stage II and 54 (64%) with stage III disease. Thirty patients that reached ASCT were evaluated at +100 days after ASCT. Immunoglobulin heavy/light chain pairs (HLC) were assessed by Hevylite assays (The Binding Site). Clinical variables were evaluated for their impact on patient´s outcome. Overall survival (OS) and progression-free survival (PFS) were evaluated by Kaplan-Meier method and Cox regression. Statistical analysis was made with Prism 6.0.

Results: The median OS of the 85 patients was 54% and 26 patients deceased during the study due to MM. The median value of i/u HLC ratio was 80 (31.5-319.71). At diagnosis, a i/u HLC ratio>80 was significantly associated with worse OS (48 *vs* 61%, p=0,005) and shorter PFS (23% *vs* 42%, p=0,006). Severe HLC-matched pair suppression (*i.e.* more than 50% below the lower reference range) was identified in 68% of the newly diagnosed patients and was associated with significantly shorter OS (35% *vs* 81%, p=0,004) and PFS (21% *vs* 50%, p=0,013). Severe (>50%) systemic immunoparesis of non-monoclonal immunoglobulins was identified in 64% of the patients at diagnosis and was also significantly associated with shorter OS (32% *vs* 81%, p=0,030) but not with shorter PFS (26% *vs* 44%, p=0,306). The evaluation of other clinical variables on patient´s outcome are shown in table (see Table). In multivariate analysis, severe HLC-matched pair suppression and albumin were found as independent risk factors for OS whereas creatinine and i/u HLC ratio >80 were found as independent risk factors for PFS. In the post-ASCT evaluation of the patients (n=30), normalization of HLC ratio was observed in 22 patients (73%). An altered HLC ratio was significantly associated with shorter PFS after ASCT (25% *vs* 70%, HR: 3,42, 95%CI 1,12-11,97, p=0,039) and with a trend towards a worse OS (p=0,072). Severe HLC-matched pair suppression was found in 12 patients (40%) and was predictive of worse OS (0% *vs* 70%, HR: 10,63, 95%CI: 1,11-114,11, p=0,023) and shorter PFS (35% *vs* 71%, HR: 8,87, 95%CI: 1,72-45,92, p=0,002). On the other hand, the severe systemic immunoparesis observed in 17 patients (57%) was not associated with OS (p=0,644) and PFS (p=0,750).

Table 1.

Variables	Overall Survival (OS)		Progression Free Survival (PFS)	
	HR (95%CI)	p-value	HR (95%CI)	p-value
Univariate analysis				
HLC ratio >80	3,13 (1,35-7,24)	0,005	2,44 (1,26-4,71)	0,006
HLC-matched pair suppression >50%	4,94 (1,47-16,59)	0,004	2,56 (1,19-5,50)	0,013
Systemic immunoparesis >50%	2,97 (1,11-7,94)	0,030	1,42 (0,72-2,80)	0,306
Serum free light chains ratio <0,03 or >32	1,07 (0,44-1,56)	0,887	1,01 (0,45-1,82)	0,774
Calcium >10,5 mg/dL	1,02 (0,38-2,74)	0,965	1,21 (0,55-2,65)	0,642
Hemoglobin <10 g/dL	1,87 (0,70-5,01)	0,216	1,38 (0,63-3,02)	0,418
Creatinine>2 mg/dL	2,73 (1,16-6,41)	0,021	2,39 (1,17-4,88)	0,017
Lytic bone lesions	1,40 (0,42-4,73)	0,586	1,93 (0,67-5,50)	0,221
Beta-2-microglobulin >5,5 mg/L	2,013 (0,84-4,80)	0,115	1,58 (0,80-3,09)	0,187
Albumin <3,5 g/dL	3,23 (1,29-8,07)	0,012	1,83 (0,94-3,56)	0,076
Bone marrow plasma cells >10%	1,07 (0,43-2,62)	0,891	1,33 (0,62-2,82)	0,465
LDH > 250 U/mL	2,08 (0,93-4,64)	0,074	1,95 (0,99-3,79)	0,05
ISS-2 (vs. ISS-1)	1,56 (0,35-7,06)	0,561	1,80 (0,58-5,53)	0,307
ISS-3 (vs. ISS-1)	2,15 (0,64-7,27)	0,219	1,92 (0,73-5,06)	0,186
Cox multivariate analysis (backward stepwise regression)				
HLC-matched pair suppression >50%	7,03 (1,64-30,09)	0,009	-	-
Creatinine>2 mg/dL	2,29 (0,96-5,46)	0,061	3,46 (1,66-7,24)	0,001
Albumin <3.5 g/dL	3,31 (1,23-8,64)	0,017	-	-
HLC ratio >80	-	-	3,75 (1,71-8,22)	0,001

Summary/Conclusions: Severe HLC-matched pair suppression and i/u HLC>80 are associated with worse OS and shorter PFS in MM patients suggesting a potential use of these parameters as prognostic biomarkers in newly diagnosed patients. Severe HLC-matched pair suppression is an independent risk factor for OS whereas i/u HLC>80 is independently associated with shorter PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparesis.

SURVIVAL STRATIFICATION OF PATIENTS WITH MULTIPLE MYELOMA (MM) AFTER FIRST RELAPSE: SENSITIVITY ANALYSES OF A NOVEL RISK STRATIFICATION ALGORITHM (RSA)

R. Hajek[1,*], M. Delforge[2], M. Raab[3], L. Pour[4], I. Špička[5], E. Gregora[6], J. Minařík[7], S. Gonzalez-McQuire[8], W. Bouwmeester[9], V. Maisnar[10]

Background: Established risk stratification tools in MM, such as the International Staging System (ISS) and the revised ISS, have improved overall survival (OS) estimates by combining the strongest known predictors of survival at diagnosis. There remains, however, a need for tools that use additional data available at relapse to improve risk stratification. We previously used real-world data from the Czech Registry of Monoclonal Gammopathies (RMG) to develop a RSA for estimating risk of death in patients with MM starting second line (2L) treatment. A multiple Cox regression model identified predictors of OS at 2L (Table); hazard ratios (HRs) for each predictor were multiplied to obtain an overall score for each patient. A K-adaptive partitioning for survival (KAPS) algorithm stratified patients into risk groups based on these scores.

Aims: To investigate how our RSA is affected by: 1) removing cytogenetic abnormalities (CAs) at diagnosis as an OS predictor, as these are not routinely measured in practice; 2) adding 2L treatment as a predictor, as 2L treatment type is likely to affect OS; 3) changing the number of stratification groups.

Methods: The analyses used data for 1418 patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and who had started 2L. The Cox model was re-run for two sensitivity analyses: excluding CAs and adjusting for treatment received at 2L (adding bortezomib or lenalidomide *vs* other treatments as a predictor). The impact of different numbers of risk groups was assessed using KAPS.

Table 1.

Predictors of OS at second line (Cox regression analysis)		Original model	Sensitivity analyses

*Factor was forced into the model.
†Category includes patients with accelerated osteoporosis or with >2 new lesions at diagnosis and at 2L.
‡'Non-refractory' and 'refractory to other (not new) drugs' were merged because patients in the latter group had good OS (unexpected effect) probably because they benefited from treatment with older drugs and had good treatment options available at 2L.
*p≤0.05; **p≤0.001; ***p≤0.0001.
2L, second line; AIC, Akaike's information criterion; CA, cytogenetic abnormality; CI, confidence interval; ECOG PS, Eastern Cooperative Oncology Group performance status; HR, hazard ratio; LDH, lactate dehydrogenase; NA, not applicable; NR, not reported; OS, overall survival.

Results: Results are shown in the Table. The model without CAs had similar HRs and predictors to the original; however, lactate dehydrogenase level at diagnosis was not identified as a predictor. Kaplan–Meier OS analysis showed separation between groups (median OS for the lowest [group 1] to the highest [group 4] risk group: 57.2, 29.4, 14.9 and 4.9 months), but the separation was weaker than when CAs were included in the model (median OS: 57.2, 28.8, 13.4 and 4.7 months). Despite 81% of patients in the RMG having no CA data, ('missing' CA was treated as a separate level in the original model), the fit of the model (measured using Akaike's information criterion; Table) without CAs was worse than the original, reducing the accuracy of survival predictions. Adding 2L treatment as a predictor did not affect the model fit, indicating that OS predictions were not improved. KAPS analysis showed that a model with three groups for stratifying patients by risk of death was less effective than one with 4 or 5 risk groups. With group 1 as the reference, the HRs for OS were 2.4 and 8.1 for groups 2 and 3 in the three-group model (all p<0.001), 2.1, 4.2 and 11.1 in groups 2–4 in the four-group model (all p<0.001) and 1.8, 2.8, 4.9 and 10.5 for groups 2–5 in the five-group model (all p<0.001). Using five risk groups was considered less practical in a clinical setting than the four-group model, which provides a clearer difference in risk across groups.

Summary/Conclusions: These analyses indicate that our RSA incorporating data from diagnosis and relapse can identify patient groups with profoundly different survival expectations, regardless of 2L treatment type. CAs at diagnosis is a known OS predictor and, as expected, improves the strength of predictions. The practicalities of measuring CAs should be considered, but these data suggest that physicians should be encouraged to assess CAs at diagnosis; CAs at relapse may also be informative. Further validation of this model is required using other real-world and clinical trial data.

E1273

REAL-WORLD DATA ON MULTIPLE MYELOMA: A PROSPECTIVE NATIONAL REGISTRY IN URUGUAY ON 224 NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS FROM 2012-2015

E. Riva[1,*], V. Bove[1], F. Villano[1], M. Mori[2], A. Noria[3], P. Petruskevicius[4], C. Córdoba[5], A. Cardeza[6,7], L. Diaz[1]
[1]Hematology Department, Hospital de Clínicas, Facultad de Medicina, [2]Hematology, Hospital Maciel, [3]Quantitative Methods Department, Facultad de Medicina, [4]Comisión Honoraria de Lucha contra el Cáncer, CHLCC, Montevideo, [5]Hematology, Centro Médico, Salto, [6]Hematology Department, Asociación Española, [7]President, Uruguayan Society of Hematology, Montevideo, Uruguay

Background: The Uruguayan National Myeloma Registry is the first observational prospective Uruguayan registry designed to document clinical characteristics of newly diagnosed multiple myeloma (MM), treatment and outcomes in a real-world setting. It collects detailed data from MM patients diagnosed at all institutions from 2012, nationwide. Analysis of this non-selected data will allow us to plan strategies to improve our local approach to this disease, reducing problems derived from extrapolating information from other realities.

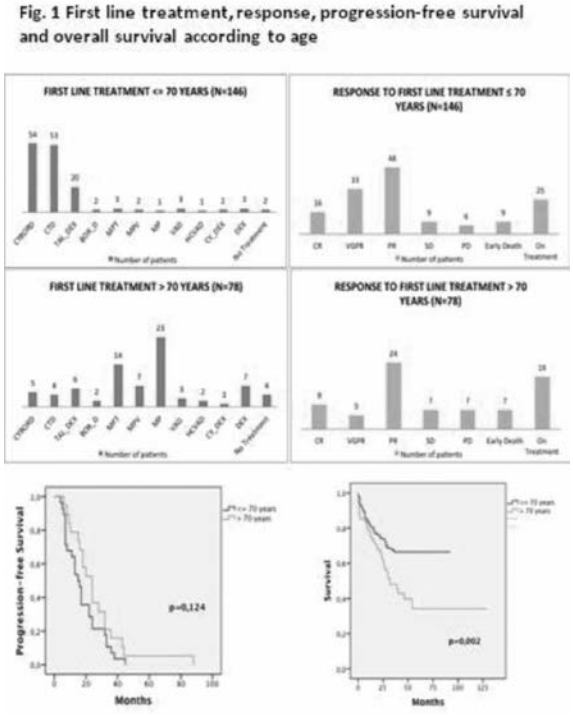

Figure 1.

Aims: To document current strategies of clinical characteristics at diagnosis, management, outcomes and treatment adverse effects of non-selected newly diagnosed MM patients in a recent period.

Methods: This registry includes all MM diagnosed from January 2012 in all institutions, nationwide. Smoldering MM are not included. We present the analysis of the first 3 years of data collection. Information was obtained from medical records at each institution. Our database includes clinical and laboratory characteristics, treatment, disease-related and treatment-related adverse events, response, progression free survival, overall survival and cause of death. Survival is obtained from the Uruguayan Ministry of Health database.

Results: With a 71% institutional coverage, 224 patients were included. Median age at diagnosis was 66 years (range 33-94 years), 54,5% were male; 10% were younger than 50 years and 34,5% older than 70 years. Distribution according Ig subtype was: IgG 50,4%, IgA 23,3%, Light chains 18,7%, non-secretor 2,2% and IgM <1%. Most patients had advanced disease: 79,6% Durie-Salmon stageIII (176/221), 48,6% ISS3 (86/177). Anemia (hemoglobin<10 g/dl) was present in 58%, osteolytic lesions in 69%, renal impairment (creatinine>2mg/dl) in 29,5% and hypercalcemia in 10%. Cytogenetics was evaluated in 150 patients; high risk features were detected in 6,3% by conventional cytogenetics and 19% by fluorescence *in situ* hybridization. First-line treatment included at least one of the new drugs (Thalidomide, Bortezomib or Lenalidomide) in 92% of patients ≤70 years and in 50% of>70 years. First-line response was available in 73%. Overall response rate (≥ PR) was 82,3%, VGPR= 23,2% and CR=15,2%; 9,8% patients achieved stable disease and 7,9% were refractory. (Fig 1.). Comorbidities and treatment-related toxicities were observed in 43,8% (47% in>70 y *vs* 41%). Most common adverse events were recurrent infections (26%), neuropathy (17%), thromboembolic events(5,4%) and grade 3-4 cytopenias(5%). Sixty out of 146 potential candidates have been transplanted as first line consolidation at the time of this analysis. After a median follow-up of 30 months, overall survival was 62,8% (median NR in ≤70 years and 32 months in>70 years) and median progression free survival (PFS) was 17 months.

Summary/Conclusions: This first national registry provides a thorough insight into the characteristics of MM patients in our country. With a high institutional coverage, we show MM characteristics at diagnosis are similar to other real-life reports.(1) MM is detected in advanced stage with a high percentage of renal impairment. Diagnosis is performed according to international recommendations. First-line treatment is defined by local policies which restrict Bortezomib to high-risk cytogenetic features and/or renal impairment and do not provide Lenalidomide. Reasons for 59% potential candidates not receiving ASCT should be addressed in future research. This analysis provides relevant real-life information to plan strategies to improve MM management and perform high quality population-based research on the field.

E1274

REPRESENTATION OF MINORITIES, THE ELDERLY AND WOMEN IN MULTIPLE MYELOMA CLINICAL TRIALS

N. Duma[1,*], J. Vera-Aguilera[1], M. Gonzalez [2], R. Parrondo[2], J. Paludo[1], V. Mariotti[2], Y. Wang[1], R. Warsame[1], R. Go[1], A. Adjei[3]
[1]Hematology, Mayo Clinic, Rochester, [2]Internal Medicine, Rutgers University, Newark, [3]Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM) accounts for approximately 1% of all cancers and 10% of hematologic malignancies in the United States (US). MM occurs in all races but the incidence in African Americans is two to three times higher than in non-Hispanic whites. Many clinical trials (CT) lack appropriate representation of specific patients populations, limiting the generalizability of the evidence obtained.

Aims: Determine the representation of ethnic minorities, the elderly and women in MM CT.

Methods: Enrollment data from all therapeutic trials reported as completed in clinicaltrial.gov from 2000 to 2016 were analyzed. CT including other hematologic malignancies and with recruitment outside of the US were excluded. Enrollment fraction (EF) was defined as the number of enrollees divided by the 2013 Surveillance, Epidemiology, and End Results (SEER) database MM complete prevalence. Chi-square test was used to estimate differences in categorical data.

Results: Out of 177 MM CT, 78 (44%) reported ethnicity with a total of 12,055 enrollees. Out of those 78 CT, 52 (67%) were phase II, 15 (19%) phase III and 11 (14%) phase I. Most of the results were published from 2012 to 2016 (74%). Distribution by race, gender, age and comparison with the SEER MM prevalence data are described on Table 1. Forty-six (59%) trials were sponsored by industry, 7 (9%) by NCI and 25 (32%) were investigator initiated. Participation in CT varied significantly across ethnic groups, non-Hispanic Whites (NHW) were more likely to be enrolled in CT (EF of 0.23) than African Americans (AA) (EF of 0.08, p <0.0001) and Hispanics (H) (EF of 0.05, p <0.0001). Males had

a higher recruitment rate than females (58% *vs* 42%), but this could be explained by the higher incidence of MM in this subgroup. Enrollee's median age was 62 years. Younger pts (<65 years) were more likely to be enrolled in CT than the elderly (66% *vs* 34%, p<0.0001). Industry sponsored trials were less likely to recruit AA compared with investigator initiated trials (7.6% *vs* 12%, p<0.0001).

Table 1.

	Trials Participants No. (%)	2013 MM Prevalence, %
Race/Ethnicity		
NHW	10,139 (84)	70
AA	1,034 (8.6)	20.2
H	227 (1.8)	7.2
Asian	342 (2.8)	2.5
Native American	13 (0.1)	N/A
Other	300 (2.5)	
Gender		
Male	7,055 (58)	53
Female	5,000 (42)	47
Age^		
<65	3,631 (66)	38
>65	1,908 (34)	62
Total enrollees	12,055	

^ reported by 46% of CT

Summary/Conclusions: Despite the higher incidence of MM in African Americans and the elderly, the former only represented 8.6% of the study participants and 66% of these were less than 65 years of age, perharps lacking data in the tolerability of these new agents in our aging MM population. We also observed industry studies were less likely to recruit AA patients. Future trials should take extra measures to recruit participants that adequately represent the United States MM population.

EVALUATION OF TREATMENT INDUCED NEUROPATHY IN MULTIPLE MYELOMA AND ITS INFLUENCE ON PHYSICAL AND ROLE FUNCTIONING

B. Sidi Mohamed El Amine[1,*], H. Asma[1], O. Fouzia[1], S. A. Najet[1], Z. Zahia[1]
[1]Hematology department, Universitary hospital of Sidi Bel Abbés, Sidi Bel Abbes, Algeria

Background: Peripheral neuropathy (PN) is a major dose limiting and potentially disabling adverse event of commonly therapeutic drugs used in the management of multiple myeloma (MM), including the immunomodulatory drugs (IMIDS, Thalidomide and Lenalidomide), and the proteasome inhibitor (Bortezomib).
Aims: The aims of this study were to (1) perform a psychometric evaluation of PN and (2) examine the prevalence of this complication and its influence on physical and role functioning of MM patients.
Methods: The FACT/GOG-Neurotoxicity (Ntx) subscale for assessing treatment induced PN was evaluated. The 11-item of this questionnaire was administered to patients with MM treated with IMIDS and/or Bortezomib. The subscale was evaluated in 32 patients for internal reliability, construct validity, criteria validity, and compared to NCI grading adverse events (CTCAE version 3). Spearman rank correlation was calculated to determine the impact of PN on functional, physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLQ-C30). A Cronbach coefficient ≥ 0,8 is good. Spearman rank correlation is significant if p< 0.05 or r >0, 5.
Results: Cronbach'alpha coefficient for infernal consistency of FACT/GOG-Ntx subscale was 0, 92, and its correlation with the full CTCAE scale as follows: P<0, 0001. All the 11 items exhibited high correlations with the NTX subscale score (r= 0, 65- 0, 79), and the Construct validity of NTX was good. According to FACT/GOG-NTX and NCI- CTCAE, 24 (75%) patients presented PN secondary to IMID or Bortezomib. The PN was severe in 14 (43, 7%) patients, especially those who received Bortezomib associated with IMIDS (71, 4%). PN did not influence the achievement of a very good response of MM to therapy neither a complete remission (P=0.6), but patients with high scores of NTX subscale have reduced functional activities, especially physical and role functioning (P=0.0005, P=0.0001 respectively).
Summary/Conclusions: The 11-item FACT/GOG-Ntx subscale reliably and validly assesses Bortezomib/IMIDS induced PN. This complication is frequent and can alter the functional abilities of MM patients.

E1276

PROGNOSTIC SIGNIFICANCE OF T(11;14) EXPRESSION BY FISH IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE ERA OF NOVEL THERAPIES

M. Gonzalez Velez[1,*], R. Parrondo[1], T. Andrews[2], N. Duma[3], J. Richter[2], D.H. Vesole[2], D.S. Siegel[2], N. Biran[2]
[1]Internal Medicine, Rutgers NJMS, Newark, [2]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, [3]Mayo Clinic, Rochester, United States

Background: Rearrangements of the immunoglobulin heavy chain (IGH) on chromosome 14 are identified by FISH in about 15-20% of patients (pts) with newly diagnosed multiple myeloma (MM). Historically there is variation on the significance on prognosis of these rearrangements: typically, t(4;14), t(14;16) and t(14;20) have high risk (HR), and t(11;14) have standard risk (SR). A recent study (Kaufman et al, Leukemia. 2016 30:633-9) suggests that t(11;14) may confer a worse prognosis.
Aims: To determine the prognostic significance of t(11;14) in a single-institution MM cohort.
Methods: 87 pts with t(11;14) by CD 138 selected FISH at diagnosis were identified, pts without symptomatic MM were excluded. Cox regression was used for statistical analysis. Progression free survival (PFS), and overall survivals (OS) from diagnosis and post autologous stem cell transplant (ASCT) were analyzed by Kaplan-Meier.
Results: Median age at diagnosis was 62 years, 45 pts (52%) were male, and 24 pts (27%) had ISS 3. All pts received either a proteasome inhibitor or an immunomodulatory agent, and 42 (48%) received triplet treatment as induction. Sixty-nine (79%) pts had ASCT, and overall response rate (ORR, partial response or better) post ASCT was 73%. For pts with HR FISH (defined as t(14;16), p53 del, 1q21 gain or 1p del) compared to SR FISH, the ORR post ASCT was 70% *vs* 77% (p=0.67). OS from diagnosis was 93% at 3 years, 74% at 4 years and 51% at 5 years. Seven patients (8%) developed plasma cell leukemia, and there was no association between HR and SR FISH (p=0.66). In multivariate analysis, ISS stage was an independent risk factor for mortality; pts with stage 3 had 7.3 times (CI: 1.16-36.4) and 5.7 times (CI: 1.63-20.0) the risk of mortality than pts with stage 1 and 2. Having an ASCT reduced mortality by 87% (CI: 0.04-0.41).
Summary/Conclusions: Despite the use of novel therapies the OS at 5 years of our pts with MM was not significantly improved compared to SEER data from 1992-2013 (51% *vs* 48.5%). Pts with t(11;14) who had ASCT had increased survival compared to those who did not. Our results suggest that t(11;14) may confer a worse prognosis. Further prospective studies evaluating the risk of t(11;14) are warranted.

E1277

ANALYSIS OF THE CONNECT MM REGISTRY: TREATMENT OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA WHO RECEIVED LENALIDOMIDE MAINTENANCE OR NO MAINTENANCE

R.M. Rifkin[1,*], S. Jagannath[2], B.G. Durie[3], J.J. Shah[4], M. Narang[5], H.R. Terebelo[6], C.J. Gasparetto[7], K. Toomey[8], J.W. Hardin[9], L. Wagner[10], K. Parikh[11], S. Abouzaid[11], S. Srinivasan[11], A. Kitali[11], F. Zafar[11], R. Abonour[12]
[1]US Oncology Research, Rocky Mountain Cancer Centers, Denver, [2]Mount Sinai Hospital, New York, [3]Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, [4]MD Anderson Cancer Center, Houston, [5]US Oncology Research, Maryland Oncology Hematology, Columbia, [6]Providence Cancer Institute, Southfield, [7]Duke University Medical Center, Durham, [8]Steeplechase Cancer Center, Somerville, [9]University of South Carolina, Columbia, [10]Wake Forest University School of Medicine, Winston-Salem, [11]Celgene Corporation, Summit, [12]Indiana University Simon Cancer Center, Indianapolis, United States

Background: Maintenance therapy post autologous stem cell transplant (ASCT) has been shown to improve clinical outcomes, including time to progression, progression-free survival (PFS), and overall survival (OS) in patients with newly diagnosed multiple myeloma (NDMM) (Sonneveld, *J Clin Oncol,* 2012; McCarthy, *N Engl J Med,* 2012; Attal, *N Engl J Med,* 2012; Palumbo, *N Engl J Med,* 2014; Attal, ASCO, 2016). However, the effect of continued treatment on healthcare resource utilization (HRU) is mostly unknown. Connect MM is a largely community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns, and outcomes in patients with NDMM in clinical practice.
Aims: This analysis used the Connect MM registry to analyze the impact of maintenance treatment on clinical outcomes and HRU in a largely community setting.
Methods: Adult patients with NDMM were eligible for enrollment in the registry within 60 days of diagnosis. Patients who completed induction and single ASCT without subsequent consolidation and received lenalidomide (LEN)-only or no maintenance were included in the analysis. HRU (hospitalization rates and length of stay, surgery/procedures, concomitant medications including growth factor, bisphosphonate, and neuropathic pain medication) was assessed from 100 days post-ASCT to the end of years 1 and 2. Data cutoff was Jan 7, 2016 and the median follow-up was 39.3 months.
Results: A total of 1493 patients with NDMM were enrolled in Cohort 1 from Sep 2009 to Dec 2011; 421 patients met the analysis criteria stipulated above. Of these, 165 did not receive maintenance therapy and 256 received any type of maintenance therapy. Of those receiving maintenance, 180 (70%) were treated with LEN-only maintenance. The median age was 60 y (range, 24-78); 60% were men, and 86% were white. Baseline patient characteristics except serum

creatinine, calculated International Staging System stage, history of monoclonal gammopathy of unknown significance, presence of del(17p), and induction regimen were similar across groups. LEN-only maintenance significantly extended PFS compared to no maintenance (median 54.5 months *vs* 30.8 months; hazard ratio [HR]=0.58 [95% CI: 0.43, 0.79]; *P*=.0005; Table). OS was also significantly improved with LEN-only *vs* no maintenance (HR=0.45 [95% CI: 0.28, 0.73]; *P*=.001). HRU results are detailed in the Table. The rate of hospitalization/100 person-years (PY) was similar across groups (*P*=not significant [NS], all comparisons) at the end of years 1 and 2. The median duration of hospitalization was numerically longer for patients who received no maintenance. Procedures/surgeries and concomitant medication use were similar across both groups at the end of years 1 and 2.

Table 1.

	LEN-Only Maintenance (n = 180)	No Maintenance (n = 165)	Hazard Ratio (95% CI)
Median PFS, months	54.5	30.8	0.58 (0.43, 0.79) *P* = .0005
Median OS, months	NR	NR	0.45 (0.28, 0.73) *P* = .001
Hospitalization rate, /100 PY			Incidence Ratio (95% CI)
Year 1	28.7	32.9	0.82 (0.44, 1.52) *P* = NS
Year 2	32.0	45.2	0.65 (0.34, 1.24) *P* = NS
Median hospitalization duration, d			
Year 1	5.0	10.5	*P* = NS
Year 2	7.0	9.0	*P* = NS

Summary/Conclusions: For patients with NDMM, LEN-only maintenance significantly improved PFS and OS *vs* no maintenance with no apparent impact on HRU.

Background: Response and follow-up criteria in multiple myeloma (MM) are still based on the protein electrophoretic (PEP) quantification of the monoclonal protein (MP) in serum (s) and / or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. Since 2001, serum free light-chain assays (sFLC) are available, with demonstrated clinical utility. *Dejoie et al.* have recently reported the usefulness of sFLC for evaluating response in LCMM.
Aims: In this work, we try to validate the use of sFLC assay in the context of GEM/PETHEMA clinical trials in order to evaluate the responses and its advantages in comparison to standard quantification of MP by PEP in serum (s) and —mainly— urine (u) after treatment, given the usual difficulties to collect and adequately perform urine studies in the usual clinical praxis.
Methods: We included 169 patients with Bence Jones (BJ) MM with measurable urine disease who have being treated according to GEM/PETHEMA clinical trials (GEM05menos65, GEM05MAS65, GEM2010MAS65 and GEM2012 menos65). Serum FLC assays (Freelite®, The Binding Site, Birmingham, UK) were performed on an automated nephelometer (BNII, Dade Behring / Siemens, Marburg, Germany). The electrophoretic study of the monoclonal component (CM) was performed by capillary electrophoresis (V8, Helena Biosciences Europe), and immunofixation was performed for the Ig, γ, κ and λ chains (SAS-3 and SAS-4, Helena Bioscience Europe).
Results: From a total of 169 patients with LCMM (93 Bence Jones kappa / 76 Bence Jones Lambda), 146 (86%) had FLC data at diagnosis, with 139/146 (95%) evaluable by FLCs [involved sFLC ≥100)]. In addition, 68 of the 169 patients also had detectable MP in serum and 7 of the 169 had non-evaluable MP in urine (MP <0.200 g/24h). We studied the correlation of both techniques' MP quantification results (uPEP *vs* isFLC) and we observed a low correlation (Pearson's r 0.293, p =0.003), that should be partly explained by the low profitability and subjectivity of the electrophoresis technique for quantifying paraprotein in urine. [Figure 1A]. The concordance between the classification of the response by uPEP / immunofixation (IF) and by FLCs (Kappa Index=0.425 p <0.0001) was moderate. The normalization of the sFLC ratio (r) was reached in 35/98 (36%) patients after treatment, associated to a lower risk of progression (normal *vs* abnormal sFLCr: PFS 60 *vs* 39 months, p =0.038) but without impact in overall survival in our series. We also observed that an absolute value of isFLC greater than 50mg/L after treatment was associated with an increased risk of progression, regardless of the response achieved (PFS 60 *vs* 28 months, p<0.0001). [Figure 1B].

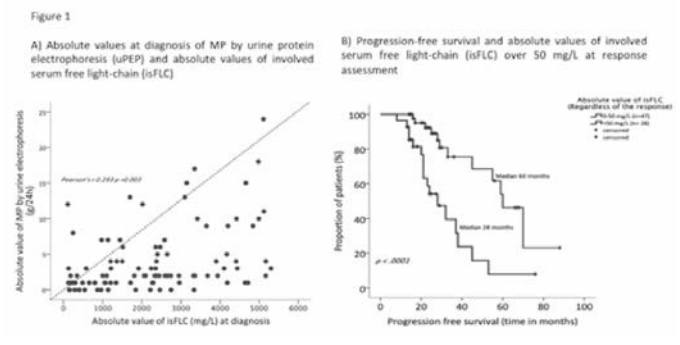

Figure 1.

Summary/Conclusions: There is an acceptable agreement between both methods for response evaluation. The sFLC assays provide a greater sensitivity than the urine protein electrophoresis for monitoring low levels of disease in certain cases with measurable disease at diagnosis (isFLC ≥100) being useful for its follow-up, and also provide prognostic value as a predictor of progression.

E1279

TOPSPIN: A NOVEL ALGORITHM TO PREDICT TREATMENT SPECIFIC SURVIVAL IN CANCER

J. Ubels[1,2,3,*], E.H. van Beers[3], A. Broijl[2], P. Sonneveld[2], M.H. van Vliet[3], J. de Ridder[1]

[1]Center for Molecular Medicine, UMC Utrecht, Utrecht, [2]Department of Hematology, Erasmus MC Cancer Institute, [3]SkylineDx, Rotterdam, Netherlands

Background: In recent years many novel treatments have been introduced for Multiple Myeloma (MM), leading to an improved survival. However, this has also led to a situation where many different treatment combinations are used, without a clear indication which patient will benefit most from which treatment. It is increasingly recognized that genetic heterogeneity between tumors influence treatment response. Patient outcomes may be improved by selecting the right treatment for the right patient at the moment of diagnosis. This requires the discovery of predictive markers, for example gene expression signatures, that can aid in this treatment decision. Here we present TOPSPIN (Treatment Outcome Prediction using Similarity between PatIeNts), a novel algorithm to discover such markers from tumor gene expression data. We use it to identify patients more likely to benefit from bortezomib.
Aims: This algorithm aims to develop a classifier that identifies a subset of patients that will benefit more from a treatment of interest than similar patients who receive a different treatment.
Methods: TOPSPIN aims to predict whether a patient will benefit (class 1) or will not benefit (class 0) from a certain treatment of interest based on the gene expression profile of the patient. This algorithm relies on the idea that genetically similar patients who received a different treatment should have a large difference in survival, given that genetic similarity is defined in a manner that is relevant to treatment response. This principle is used to identify prototype patients: patients who received the treatment of interest and have a larger than expected survival difference with the genetically most similar patients who received another treatment. Genetic similarity is defined separately for 10 581 gene sets based on Gene Ontology (GO) annotation. These prototype patients are used to define a classifier: new samples who exhibit a similar gene expression profile as these prototypes are also expected to benefit more from the treatment of interest. Here we use TOPSPIN to predict which patients will benefit from the proteasome inhibitor bortezomib. We combine tumor gene expression data from the Total Therapy 2, Total Therapy 3 and HOVON-65/GMMG–HD4 phase III clinical trials into one dataset comprising 910 patients, split into a bortezomib arm (n=407) and a non-bortezomib arm (n=503). Progression free survival is used as outcome measure. This dataset was split in a training set (n=606) and a test set (n=304). The test set is not used at any point in the training procedure and is only used for independent validation.

Results: We successfully identify gene sets that enable us to predict which patients will benefit most from bortezomib. The top 8 performing GO sets based on Hazard Ratio (HR) were combined to achieve the final classification. In the training set 28.4% of patients are classified a class 1, resulting in an HR of 0.13 ($p=7.1*10^{-11}$) between the two treatment arms. More importantly, in an independent test set an HR of 0.47 (p=0.03) was found, as shown in Figure 1.

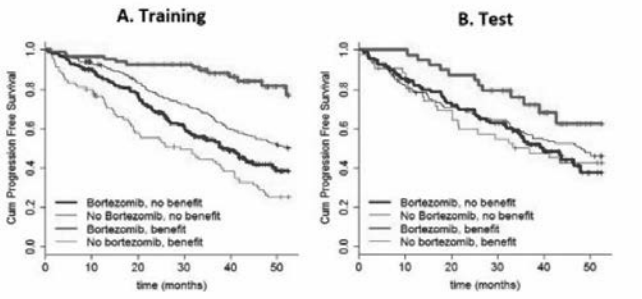

Figure 1. A. Kaplan Meier of training set classification, showing a large survival benefit for patients receiving bortezomib in class 1 (red lines) but not in class 0 (blue lines). B. Kaplan Meier of the test set classification, validating the classifier found on the training set.

Figure 1.

Summary/Conclusions: TOPSPIN is successful in predicting bortezomib specific survival in independent data. TOPSPIN can be applied to any dataset with two treatment arms and a continuous outcome measure. In a disease like MM, where many different treatment are available, selecting the right treatment is critical and TOPSPIN can aid in this decision.

E1280

AMYLOIDOSIS RESEARCH CONSORTIUM CARDIAC AMYLOIDOSIS SURVEY: RESULTS FROM PATIENTS WITH AL AMYLOIDOSIS AND THEIR CAREGIVERS

I. Lousada[1,*], M. Maurer[2], S.D. Guthrie[3], K. Hsu[1], M. Grogan[4]
[1]Amyloidosis Research Consortium, Boston, [2]Columbia University, New York, [3]Prothena Biosciences Inc, South San Francisco, [4]Mayo Clinic, Rochester, United States

Background: Cardiac amyloidosis is a severe disease that can lead to cardiac dysfunction and death. Amyloid light chain (AL) amyloidosis, hereditary transthyretin (hATTR) amyloidosis, and wild-type transthyretin (wtTTR) amyloidosis may result in cardiac amyloidosis. AL amyloidosis is caused by an accumulation of misfolded light chain and often involves organs other than the heart (eg, kidneys, nervous system). Initial symptoms are often nonspecific (eg, weight loss, fatigue). Consequently, a diagnosis is frequently made only after the disease has become advanced. Previous patient-directed research found that despite patients being initially referred most often to cardiologists (as opposed to hematologists and nephrologists), cardiologists diagnosed the condition much less frequently than other specialists.
Aims: To understand delays, errors, and inconsistencies in the diagnostic pathway for patients with AL cardiac amyloidosis and validate using caregiver responses.
Methods: An online survey consisting of 36 questions (for patients) and 37 questions (for caregivers) was developed by the Amyloidosis Research Consortium (ARC) and distributed to the patient mailing lists of ARC, the Amyloidosis Foundation, and Amyloidosis Support Groups in January 2017. The survey was designed for patients with all forms of cardiac amyloidosis and their caregivers; however, the present analysis is limited to AL amyloidosis.
Results: In this subanalysis, 137 patients and 115 caregivers completed the survey. Most patient respondents were >55 years of age (n=111; 81.0%); of those, 16.1% (n=22) were >70 years of age. Composition of the population was 81.8% white/Caucasian (n=112), 2.2% Asian (n=3), 4.4% African American (n=6), 2.2% Latino (n=3), 5.1% other (n=7), and 3.6% unknown (n=5). Most patients had lived with their diagnosis for >1 year (17.5% [n=24] <1 year; 23.4% [n=32] 1-2 years; 29.2% [n=40] 3-5 years; 21.2% [n=29] 6-10 years; 8.8% [n=12] >11 years). A significant percentage of patients had multiorgan involvement (54.7% [n=75] kidney; 29.9% [n=41] nerve; 14.6% [n=20] liver; 43.8% [n=60] GI; 14.6% [n=20] skin; 22.2% [n=49] other site). Before diagnosis, 43.8% (n=60) of patients were incorrectly diagnosed with one or more other conditions, predominantly by cardiologists and general practitioners (Table 1). Furthermore, more than 75% of patients visited 3 or more different physicians before diagnosis. Nearly all misdiagnosed patients (83.3%; n=50/60) reported receiving treatment for their misdiagnosed condition. Both patients and caregivers reported correct diagnoses being made most frequently by cardiologists and hematologists (Table 1). Caregivers echoed the multitude of distinct physicians visited before diagnosis (Table 1). Patients reported that biopsy of fat pad, kidney, or heart was the predominant diagnostic test performed (Table 1). Hospitalization was prevalent; 55.5% (n=76) patients reported amyloid-related cardiac hospitalization. Moreover, 31.3% (n=43) of patients reported the need for air travel for physician consultation.

Table 1.

Table 1. Patient and Caregiver Survey Responses, %, (n)*

Patients: Have you had any of the following tests/procedures?†					
Fat Pad Biopsy	Kidney Biopsy	Heart Biopsy	PYP/DPD Scan	Rectal Biopsy	Unsure
54.7 (75)	29.9% (41)	29.2% (40)	13.9% (19)	12.4% (17)	4.4% (6)

How many different doctors were seen before correct diagnosis?						
	1	2	3	4	>5	unknown
Patient	10.2% (14)	13.9% (19)	24.1% (33)	13.1% (18)	38.7 (53)	-
caregiver	11.3% (13)	17.4% (20)	21.7% (25)	13.0% (15)	19.1 (22)	17.4% (20)

What type of physician made the diagnosis?						
	Cardiologist	Hematologist	Nephrologist	Neurologist	Internist	Other/unknown
patient	18.2% (25)	35.0% (48)	17.5% (24)	1.5% (2)	4.3% (6)	23.4% (32)
caregiver	19.1% (22)	21.7% (25)	20.9% (24)	0.9% (1)	4.3% (5)	33.0% (38)

Patients: What type of doctor told you that you had something other than amyloid? †						
Cardiologist	GP	Internist	Other	Neurologist	Hematologist	Nephrologist
40.1% (55)	34.3% (47)	25.5% (35)	22.6% (31)	13.1% (18)	8.8% (12)	6.6% (9)

* not all respondents answered all questions
† respondents could check all answers that applied

Summary/Conclusions: This represents the first survey compiling both caregiver and patient experiences with AL amyloidosis. Alignment of caregiver with patient responses validates our patient-directed research. Patients with AL cardiac amyloidosis frequently receive misdiagnoses and sometimes receive incorrect treatment for the misdiagnosed condition. Disease awareness among all specialists is vital, especially among those to whom patients are initially referred due to the nature of their initial symptoms.

E1281

EFFICACY OF DARATUMUMAB-BASED REGIMENS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA – A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

M.A. Dimopoulos[1,*], K. Weisel[2], J. Kaufman[3], P. Sonneveld[4], M. Rizzo[5], Y. Xu[6], K. Fahrbach[6], M. Gaudig[7], M. Slavcev[8], L. Dearden[8], A. Lam[8]
[1]National and Kapodistrian University of Athens, Athens, Greece, [2] Universitaetsklinikum Tuebingen der Eberhard-Karls-Universitaet, Abteilung fuer Innere Medizin II, Tuebingen, Germany, [3]Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, United States, [4]Department of Hematology, Erasmus MC, Rotterdam, Netherlands, [5]Evidera, London, United Kingdom, [6]Evidera, Waltham, MA, United States, [7]Janssen-Cilag, Neuss, Germany, [8]Janssen Global Services, LLC, Raritan, NJ, United States

Background: Daratumumab is a new monoclonal antibody aimed to improve outcomes in relapsed or refractory multiple myeloma (RRMM), and has been investigated in combination with lenalidomide plus dexamethasone (DRd), and with bortezomib plus dexamethasone (DVd), in randomized controlled trials (RCTs), POLLUX and CASTOR, respectively. Although DRd and DVd have been compared against current standard of care (SOC), namely Rd, and Vd, it is important to assess how daratumumab plus SOC compares with other routinely used treatment regimens and investigational regimens expecting regulatory approvals.

Table 1. NMA Efficacy Results.

Network	Comparison	PFS		OS	
		HR (95% CrIs)	Prob DRd/DVd better than comparator*	HR (95% CrIs)	Prob DRd/DVd better than comparator*
IMiD-containing	DRd vs. Rd	**0.37 [0.27, 0.51]**	100.0%	**0.63 [0.42, 0.95]**	98.7%
	DRd vs. KRd	**0.54 [0.37, 0.78]**	100.0%	0.80 [0.50, 1.28]	83.1%
	DRd vs. ERd	**0.54 [0.37, 0.80]**	99.9%	0.82 [0.51, 1.30]	80.0%
	DRd vs. NRd	**0.50 [0.33, 0.74]**	100.0%	0.70 [0.42, 1.15]	91.9%
IMiD-free	DVd vs. Vd	**0.33 [0.26, 0.42]**	100.0%	**0.63 [0.42, 0.95]**	98.6%
	DVd vs. Kd	**0.62 [0.45, 0.86]**	99.8%	0.80 [0.48, 1.34]	80.5%
	DVd vs. FVd	**0.48 [0.35, 0.65]**	100.0%	0.67 [0.43, 1.05]	95.9%
	DVd vs. CVd	**0.46 [0.26-0.82]**	99.6%	0.54 [0.24, 1.23]	92.9%

**100% probability represent any value above 99.951%*

Aims: Therefore, the objective of this analysis is to compare DRd and DVd with other relevant treatment options via network meta-analysis (NMA) techniques.
Methods: A systematic literature review (SLR) based on searches of Medline, Embase, and the Cochrane Library was conducted to identify and then assess RCTs of treatments for RRMM. The specific studies of interest were those that had investigated the efficacy of other treatment options considered to be comparators to DRd or DVd. Data from trials that met the SLR's inclusion criteria and the most recent data from POLLUX and CASTOR were extracted and then included in a Bayesian NMA to allow for the indirect comparison.
Results: Data from RCTs identified by the SLR allowed formulation of two evidence networks. Network 1 included DRd and other immunomodulatory agent (IMiD)-containing regimens, and Network 2, contained DVd and other

immunomodulatory agent (IMiD) -free regimens. Analysis using a fixed-effects model found that DRd compared with other IMiD-containing regimens in Network 1, and DVd compared with other IMiD-free regimens in Network 2 prolonged PFS and OS among patients RRMM (see Table 1).
Summary/Conclusions: In the absence of prospective head-to-head trials, NMA provides potentially important information on comparative effectiveness of different treatments. This NMA suggests that the combinations of DRd and DVd are effective in improving PFS in patients with RRMM with similar trends found for OS when compared with other established and new regimens.

E1282

TRENDS IN TREATMENT PATTERNS AND SEQUENCING IN PATIENTS WITH MULTIPLE MYELOMA DIAGNOSED 2011-2016 IN THE UNITED STATES USING AN ENHANCED ELECTRONIC HEALTH RECORDS DATABASE

B. Ung[1], S. Abouzaid[1,*], Q. Ni[1], K. Parikh[1], A. Agarwal[1]
[1]Celgene Corporation, Summit, NJ, United States

Background: Over the past few years, the multiple myeloma (MM) treatment (Tx) landscape has changed considerably. Immunomodulating (IMiD®) drugs and proteasome inhibitors (PI) have emerged as mainstays of MM Tx. However, the limitations and lag time of available administrative claims databases make it difficult to assess current real-world trends in the Tx of MM.
Aims: The study aimed to describe trends in demographics, Tx patterns, and sequencing for newly diagnosed MM (ndMM) patients (Pt) in the United States (US) using an enhanced Electronic Health Records (EHR) database.
Methods: A retrospective observational study of ndMM Pts was conducted utilizing EHR from a nationally-representative database (Flatiron Health). The Flatiron MM provider network comprises over 260 clinics throughout the US. Pts with an ICD-9 (203.0x) or ICD-10 (C90.xx) diagnosis of MM between 01/01/2011–12/31/2016 were randomly selected into the study. Pts were excluded if they did not have ≥2 documented clinical visits during the study period. Diagnosis of MM was confirmed through review of unstructured chart data. Index date was defined as the Pt's date of diagnosis with MM. NdMM Pts were defined as those without a MM Tx more than 14 days prior to their first diagnosis date. Start of first-line (1L) therapy was defined as the 1st episode of an eligible systemic Tx given after or up to 14 days before the index date. Regimens were defined using the 1st eligible drug episode plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.
Results: For the 3367 ndMM Pts identified, mean(SD) age was 68.5(11) years at the time of diagnosis, 45.9% were female, 57.6% were white, 14.7% African American, and 11.1% other race. The most common immunoglobulin (Ig) classes at diagnosis were IgG (51.8%) and IgA (18.9%). Median follow-up time for ndMM Pts was 15.9 months. During the study period, 1611 received only 1 line (L), 737 were treated with 2L, 325 with 3L, 252 with 4L+; while 442 (13%) received no Tx. Mean follow-up time for these groups was 471, 730, 928, 1132, and 610 days respectively. Among treated Pts, 205 (12.7%), 208 (28.2%), 109 (33.5%), and 98 (38.1%) received at least 1 stem cell transplant (SCT), respectively. Of Pts receiving 1L therapy, 984 (33.6%) received IMiD compound +PI, 715 (24.4%) received PI-based, and 556 (19%) received IMiD compound-based therapy in 1L. The use of IMiD compound +PI in 1L increased during the study period for SCT and non-SCT Pts (NSCT) from 40.6% and 21.5% in 2011, to 66.7% and 46.8% in Pts diagnosed in 2016. In Pts who received a SCT (n=618), the most common 1L regimens were lenalidomide + bortezomib + dexamethasone (RVd; n=217, 43.9%), cyclophosphamide + bortezomib + d (CyBord; n=124, 20.1%), lenalidomide + d (Rd; n=70, 11.3%), and bortezomib + d (Vd; n=57, 9.2%). In NSCT Pts (n=2307), the most common 1L regimens were RVd (n=642, 27.8%), Vd (n=510, 22.1%), and Rd (n=412, 17.9%). Among the RVd NSCT Pts with a documented 2L (n=189), the most common 2L regimens were CyBord (13.2%), carfilzomib monotherapy (7.4%), pomalidomide + d (6.9%), and carfilzomib + d (6.9%). Documented death occurred in 785 (23.3%) Pts during the study period.
Summary/Conclusions: Over time, RVd has become the most common 1L regimen for SCT and NSCT Pts with ndMM. After a median follow up of 15.9 months, many patients remain in the initial LOT. With a longer follow up time, we will able to observe sequencing and patterns of treatment in later LOTs.

E1283

HLC PAIR SUPPRESSION AS A RISK FACTOR FOR BLOODSTREAM INFECTIONS AND EARLY DEATH IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

J.L. García De Veas Silva[1,*], M.D.S. López Vélez[1], C. Bermudo Guitarte[2], N. Barbosa de Carvalho[3], R. Rios Tamayo[4], M. Jurado Chacón[4], T. De Haro Muñoz[1]
[1]Department of Laboratory Medicine, Complejo Hospitalario Universitario de Granada, Granada, [2]Department of Clinical Biochemistry, Hospital Universitario Virgen Macarena, Sevilla, [3]The Binding Site, Barcelona, [4]Department of Hematology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: Infection is a major cause of morbidity and mortality in patients with Multiple Myeloma (MM), responsible for 10-25% of deaths within 6 months of diagnosis. It is associated with suppression in primary antibody response (systemic immunoparesis (SI)), which may be aggravated following anti-myeloma therapy. Recently, the suppression of the non-monoclonal immunoglobulin pair (e.g. IgG-Lambda in IgG-Kappa MM), termed heavy+light chain (HLC) pair suppression, has been associated with poor prognosis in MM. However, the impact of HLC pair suppression as a risk factor for bloodstream infections has not been reported.
Aims: To evaluate HLC pair suppression as a risk factor for bloodstream infections and early death in MM patients.
Methods: The study retrospectively included 114 consecutive MM patients with diverse bloodstream infections, identified during investigation into unexplained fever and hospitalisation. Bloodstream infection was defined as a positive blood culture related to a febrile episode. The population consisted of 66 male:48 female patients, with a median age of 68 (56-77) years. The monoclonal immunoglobulin isotype was: 49 IgG-K, 26 IgG-L, 21 IgA-K and 18 IgA-L. In order to explore the impact of HLC pair suppression on bloodstream infections and early mortality, only events within 6 months (180 days) from diagnosis were documented. HLC pair suppression was defined as suppression in the levels of the non-monoclonal pair by >50% below the lower limit of the reference range. HLC measurements were carried out using Hevylite® immunoassays (The Binding Site) on a SPA_{PLUS} analyser. SI was defined as levels of the alternate immunoglobulins (e.g. IgA and/or IgM in an IgG patient) more than 50% below the lower reference range. Association between variables were analysed by Chi-square test and survival was estimated using Kaplan-Meier method.
Results: At diagnosis, HLC pair suppression was observed in 72 (63%) patients, and SI in 52 (45%). The incidence of bloodstream infections during the study period was 23%; and 20 patients (18%) died within 6 months from diagnosis. We found a significant association between HLC pair suppression and both the occurrence of bloodstream infections (OR: 6.10, 95% CI: 1.71-21.83; p=0.002) and early deaths (OR: 4.02, 95% IC: 1.10-14.66; p=0.03); by contrast SI had no significant association with either event (p=0.07 and p=0.3, respectively). Survival analyses demonstrated an association between bloodstream infections and shorter OS (50% *vs* 92%, HR: 7.43, 95% CI: 2.96-18.61, p<0.0001, Figure A). The risk of bloodstream infections was significantly higher among patients with HLC pair suppression *vs* those without suppression (34% *vs* 7%, respectively; HR: 5.12, 95% CI: 1.54-17.07, p=0.003, Figure B). In line with this, patients with HLC pair suppression had shorter overall survival (OS) compared to those without (76% *vs* 93%, HR: 3.47, 95% CI: 1.02-11.83, p=0.03). By contrast we found no association between SI and risk of infection (p=0.08) or survival (p=0.4).

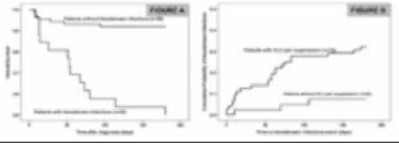

Figure 1.

Summary/Conclusions: HLC pair suppression provides information on immune status and associates with an increased risk of bloodstream infections and early deaths in newly diagnosed MM patients. Our findings highlight the importance of recognising this status at time of diagnosis, and suggest that HLC pair suppression may help guide clinical decisions about the need for adequate antimicrobial treatment during myeloma therapy.

E1284

DARATUMUMAB SIGNIFICANTLY IMPROVED PROGRESSION-FREE SURVIVAL IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA

D. Katalinic[1,*]
[1]Depatment of Internal Medicine, Faculty of Medicine, J.J. Strossmayer University of Osijek, Osijek, Croatia

Background: Daratumumab is a human IgG1k monoclonal antibody which binds with high affinity to the CD38 molecule on the surface of multiple myeloma cells. It induces rapid tumor cell death through multiple immune-mediated mechanisms and showed encouraging results alone and with lenalidomide and dexamethasone in a phase 1-2 study involving patients with relapsed multiple myeloma.
Aims: The primary end point of the study was progression-free survival.
Methods: We enrolled a total of 134 patients (74 male and 60 feemale, mean age 65.4±18.2 years) with multiple myeloma who had received at least three lines of therapy to receive lenalidomide with dexamethasone (68 patients, control group A) or in combination with daratumumab (66 patients, therapy group B).

Results: At a median follow-up of 9.8 months in a protocol-specified interim analysis, 67 patients had disease progression or death were observed (in 18 of 66 patients (27.2%) in the group B *vs* 28 of 68 (41.1%) in the control group (p<0.001)). A significantly higher rate of overall response was observed in the group B than in the group A (88.7% *vs* 62.9%, p<0.001), as was a higher rate of complete response or better (39.2% *vs* 16.1%, p<0.001). The most common adverse events during the treatment was myelotoxicity (neutropenia in 68.6% of the patients in the therapy group B *vs* 42.1% of those in the control group A), anemia (in 21.5% *vs* 13.6%) and thrombocytopenia (in 13.8% *vs* 8.7%).
Summary/Conclusions: In patients with relapsed multiple myeloma, the addition of daratumumab to lenalidomide and dexamethasone appeared active and resulted in significantly improved progression-free survival. However it was associated with a higher risk of myelotoxicity.

E1285

COMPARISON BETWEEN IMMUNOFIXATION NEGATIVITY AND NORMAL FREE LIGHT CHAIN RATIO WITH MULTICOLOUR FLOW CYTOMETRY FOR RESPONSE ASSESSMENT IN PATIENTS WITH MULTIPLE MYELOMA WITH VGPR OR BETTER

K. Narita[1,*], H. Takamatsu[2], Y. Abe[1], Y. Usui[1], M. Takeuchi[1], K. Matsue[1]
[1]Department of Medicine, Hematology/Oncology Kameda Medical Center, Kamogawa, [2]Department of Hematology and Respirology, School of medicine, Institute of Medical, Pharmaceutical and Health Sciences,Kanazawa University, Kanazawa, Japan

Background: Urine and serum Immunofixation electrophoresis (uIFE and sIFE, respectively) and free light chain assay (FLC) are widely accepted as standard tests for diagnosis and monitoring of multiple myeloma (MM). However, there is significant discordance between the electrophoretic method and FLC test for response assessment. Despite this discordance, previous studies did not address the differences in assessment of treatment response between the intact immunoglobulin MM (IIMM) and light chain only MM (LCMM)/oligosecretory MM (OSMM). uIFE results are poorly correlated with the serum FLC level, however, treatment response of LCMM has still been recommend to assess by 24-hour uIFE by International Myeloma Working Group guideline. However, MRD levels on uIFE negativity or normal FLC ratio (rFLC) in patients with various types of MM have not been studied.
Aims: To explore the relationship between uIFE, sIFE negativity and normal rFLC for MRD assessment in patients with IIMM and LCMM.
Methods: We initially selected 162 patients with MM (LCMM and OSMM, *n* = 41; IIMM, *n*=21) that received treatment at Kameda Medical Center, Kamogawa-shi, Japan and Kanazawa University Hospital, Kanazawa-shi, Japan between April 2008 and January 2016. Among them, 126 patients (LCMM/OSMM 40, IIMM 86), who achieve VGPR or better response, were selected on the basis of the availability of simultaneous serum and urine test, FLC data, and bone marrow MRD. To explore the relationship between uIFE and sIFE negativity and normal rFLC, MRD levels were compared by multicolour flow-cytometry (MFC) in patients with LCMM/OSMM, and IIMM that obtained VGPR or better. MRD negativity was defined as MRD $<10^{-4}$. Complete response (CR) was divided into conventional CR (cCR, CR but MRD-positive) and MRD$^-$CR (CR and MRD-negative)
Results: One hundred and fifty-four complete IFE, FLC, and MFC data set of 126 patients (LCMM/OSMM 40, IIMM 86) with ≥ VGPR were analysed. Normal FLC at VGPR, cCR and MRD$^-$CR was 65.0%, 78.4% and 78.6% in IIMM, and 0%, 21.4% and 100%, respectively, in LCMM/OSMM. The percentages of sample at MRD levels of MRD $\geq 10^{-3}$, 10^{-3} ≥MRD $>10^{-4}$ and 10^{-4}>MRD in LCMM/OSMM were 12.5%, 50.0%, and 100% for negative uIFE, and 0%, 11.5% and 100% for normal rFLC, respectively. These figures in IIMM were 23.0%, 41.6%, 81.4% for negative sIFE, and 53.8%, 75.0% and 88.8% for normal rFLC, respectively. Positive/negative predictive value (PPV/NPV) of uIFE and rFLC for MRD in LCMM/OSMM was 100%/54.8% and 100%/85.0%, respectively, while those were 90.6%/45.8% and 88.9%/32.4% in IIMM, respectively.

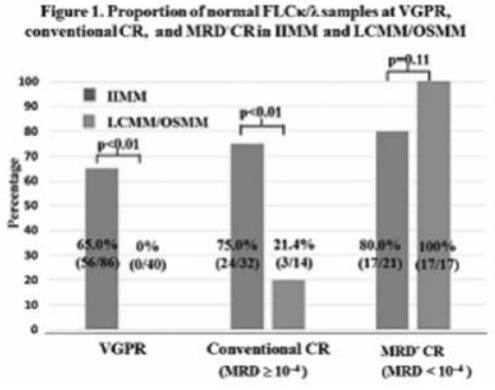

Figure 1.

Summary/Conclusions: Our observations confirmed that FLC test has greater sensitivity than uIFE for detection of the monoclonal component, and that normalization of sFLC ratio is highly predictive of MRD negativity in patients with LCMM/OSMM. The proportion of negative sIFE samples increased with depth of MRD, but the FLC response did not appear to parallel with the depth of response in IIMM. We recommend that FLC test should be incorporated into response assessment in LCMM/OSMM as an alternative to 24-h uIFE, and both negative sIFE and normal rFLC are still useful for response assessment of residual clonal PCs in IIMM.

E1286

DARATUMUMAB IS AN EFFECTIVE AND SAFE SALVAGE THERAPY IN RELAPSED/REFRACTORY PATIENTS WITH MULTIPLE MYELOMA AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

E. Klyuchnikov[1,*], U.-M. von Pein[1], F. Ayuk[1], M. Christopeit[1], R. Adjalle[1], A. van Randenbourgh[1], C. Wolschke[1], N. Kroeger[1]
[1]Department for Stem Cell Transplantation, University Cancer Center Hamburg-Eppendorf, Hamburg, Germany

Background: Daratumumab is a human monoclonal antibody that targets CD38, a cell surface protein that is overexpressed on multiple myeloma cells. The drug became the first monoclonal antibody as single agent therapy approved by the FDA for the treatment of multiple myeloma. The role of allo-SCT in myeloma patients (pts) remains unclear; nevertheless, the registry study of EBMT suggests an increasing rate of allografts in Europe in last years. Despite the potentially curative potential of this approach, the increased relapse rate and low PFS remain a central clinical problem.
Aims: In this single center retrospective analysis, we report on our experience on the use of daratumumab in relapsed/refractory myeloma pts after allo-SCT.
Methods: A total of 16 pts (male, n=9) with median age of 66 years (39-72) relapsing after allo-SCTs that had been performed during a period 2008-2015 at the University of Hamburg and received daratumumab as single agent salvage therapy. Before allografting 9 pts received one and 7 pts ≥2 autografts, respectively. All but one pt received at least 1 salvage therapy line prior to the allo-SCT. The allografts were performed from unrelated donors (MUD, n=9; MMUD, n=4) or matched related donors (MRD, n=3). The median number of salvage lines post-transplant and prior to first daratumumab infusion was 3 (1-4). The salvage regimens included bortezomib, lenalidomide, pomalidomide and carfilzomib. Daratumumab infusions were started at a median of 21 months (0-30) after relapse/progress.
Results: The median number of infusions was 13 (3-22). A total of 16 and 15 pts were available to safety and efficacy evaluation, respectively. The safety was assessed according to the Common Toxicity Criteria (CTC). A total of 20 adverse events were observed in 16 pts: dyspnea (CTC1, n=3; CTC2, n=1), bronchospasm (CTC2, n=2) shivering (CTC1, n=3), cough (CTC1, n=1; CTC2, n=1), musculoskeletal pain (CTC1, n=4), acute coronary syndrome (CTC3, n=1), skin rush (CTC2, n=1), pressure on eyes (n=1). Two patients developed late onset infections (pneumonia and infection of urinal tract) followed by temporarily therapy interruption. We observed a decrease of Tregs ($CD4^+CD25^{int/high}CD127^{low}$) number from a median of 5,05% at start to 0,65% at day 21 after first daratumumab infusion in four pts. There were no cases of GvHD. The adverse events appeared in all pts after the first infusion, with improved tolerance of following infusions. There were no cases, where the therapy had to be stopped due to adverse events. Within a median follow-up of 32 months (1-45) from the relapse/progression 12 of 16 pts remain alive. Two pts died due to progress of myeloma and another 2 pts died due to severe infection/sepsis. A total of 9 of 15 evaluable pts responded (60%, PR, n=7, vgPR, n=2). The responses (decrease of paraprotein and/or free light chains; reduction of extramedullary tumor in 2 pt) occurred at a median of 7 days (7-75) after the first administration of daratumumab. The median response duration is 4.5 mo (1.5-8). Six pts show ongoing responses. All responding and 2 non-responding pts (stable disease) showed clinical improvement of constitutional symptoms.
Summary/Conclusions: Daratumumab demonstrated encouraging efficacy in relapsed/refractory pts with myeloma after allo-SCT. The administrations of the drug in these heavily pre-treated pts were associated with good safety profile and development mostly non-severe adverse events mostly after the first infusion. Further studies on the use of daratumumab in post-transplant setting are warranted.

E1287

PROGNOSTIC RELEVANCE OF VEGF AND VEGFR EXPRESSION IN CD138+/CD19- AND CD138+/CD19+ PLASMA CELLS FROM PATIENTS WITH MONOCLONAL GAMMOPATHIES

C. Geraldes[1,2,*], A.C. Gonçalves[2,3], R. Alves[2,3], E. Cortesão[1,2,3], L. Ribeiro[1], J.M. Nascimento Costa[3,4], A.B. Sarmento-Ribeiro[1,2,3]
[1]Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), [2]Applied Molecular Biology and University Clinic of Hematology, [3]CIMAGO, [4] University Clinic of Oncology, Faculty of Medicine University of Coimbra, Coimbra, Portugal

Background: Vascular endothelial growth factor (VEGF) is a potent angiogenic peptide with biologic effects that include regulation of extracellular matrix remodeling and inflammatory cytokine generation with an important role in the bone marrow microenvironment of multiple myeloma (MM). Angiogenesis is enhanced in the bone marrow of MM patients in parallel with tumor progression. Myeloma and stromal cells secrete angiogenic factors that include VEGF. Previous studies showed heterogeneity in the expression of VEGF between plasma cells (PCs) from the same MM patient. However, no clear association with expression levels, phenotypic subtypes of PCs and prognosis was demonstrated.
Aims: The present study aimed to evaluate the expression levels of VEGF and VEGF receptor (VEGFR) on phenotypic subtypes of PCs in patients with monoclonal gammopathies and to explore its role as diagnostic and prognostic biomarkers.
Methods: We include 128 patients with monoclonal gammopathies, 60 patients with newly diagnosed symptomatic MM and 68 with monoclonal gammopathy of uncertain significance (MGUS) and also from 11 non-neoplastic controls (Ctr). We evaluated the expression levels of VEGF and VEGFR by flow cytometry in the two populations of bone marrow PCs, identified by gating CD138+/CD19- (clonal PCs) and CD138+/CD19+ (non-clonal PCs). The results are presented as percentage of PCs expressing VEGF/VEGFR and as expression levels of this antiangiogenic molecules expressed in mean intensity of fluorescence (MIF). The effects of these parameters on progression-free survival (PFS) and overall survival (OS) were analyzed with Kaplan-Meier method. For statistical analysis, software IBM SPSS Statistics v22 was used. ROC curves were performed to assess the VEGF and VEGFR accuracy as diagnostic and prognostic biomarkers.
Results: In our cohort of patients, median age was 70 (39-86) years, 52% were male. We found increased expression levels of VEGF in CD138+/CD19- PCs from MM (80±7,5 MIF) compared tomgUS patients (61,7±6,2 MIF) (p=0,011), and also higher to the observed in CD138+/CD19+ PCs (39,92±1,74 MIF) in both populations of patients (p<0,001 and p=0,02, respectively). No differences were observed in the expression levels of VEGF in CD138+/CD19+ PCs from MM (39,92±1,74 MIF),mgUS patients (41,18±1,92 MIF) and controls (32,8±1,5 MIF). However, the percentage of CD138+/CD19+ cells expressing VEGF was significantly higher inmgUS (39,4±4%) and in MM patients (46,7±4,5%) compared to Ctr (13,5±0,5%)(p=0,019 and p=0,003, respectively). The differential expression of VEGFR showed thatmgUS patients with VEGFR levels higher than 23,5 MIF in CD138+/CD19- PCs have higher probability to progress to MM [AUC 0,688 (95%CI 0,592-0,784), p<0,0001, 90% sensitivity, 56% specificity, 65% PPV, 84% NPV]. In MM patients, we also found an association between increased VEGF expression levels in CD138+/CD19- PCs (³175 MIF) and inferior PFS (p=0,002) and OS (p=0,003), irrespective of first line therapy (bortezomib-based regimens for fit patients or alkylating-based treatments for unfit patients). Interestingly, we also observed an increased percentage of CD138+/CD19+ PCs (³21%) expressing VEGF in MM patients with a more favorable PFS (p=0,04) and OS (p=0,008).
Summary/Conclusions: The results of our investigation showed that CD138+/CD19- and CD138+/CD19+ PCs have differences in what concerns VEGF/VEGFR expression, not only in MM patients, but also inmgUS patients. The increased expression of VEGF in clonal PCs from MM compared tomgUS patients evidences the relevance of VEGF in myelomagenesis. We also demonstrated a negative prognostic impact of an increased VEGF expression in CD138+/CD19- PCs, highlighting the role of VEGF in the survival and maintenance of clonal PCs and as a predictor of outcome in MM progression. The association between the percentage of CD138+/CD19+ PCs and survival supports the suggestion that these cells may not be neutral players in the complex pathogenesis of MM. The results of our study should be further investigated in larger series of patients.

E1288

RACIAL DIFFERENCES OF FISH ABNORMALITIES IN MINORITIES WITH MULTIPLE MYELOMA: A SINGLE-CENTER EXPERIENCE

M. Gonzalez Velez[1,*], V. Jaramillo Restrepo[2], N. Duma[3], M. Palascak[4], M. McKenna[4], J. Richter[5], D. Vesole[5], D. Siegel[5], N. Biran[5]
[1]Internal Medicine, Rutgers NJMS, Newark, United States, [2]CES University, Medellin, Colombia, [3]Mayo Clinic, Rochester, [4]Saint George University, [5]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, United States

Background: Racial disparities of FISH abnormalities in multiple myeloma (MM) have been well described in whites (W) but partially described in minorities (M) (Paulus et al, ASH 2016, 4432).
Aims: To explore racial-based differences of FISH abnormalities using the largest cohort of minorities to date.
Methods: CD-138 selected FISH was done on 799 consecutive patients (pts). Pts without symptomatic MM, and biopsy >6 months after diagnosis were excluded. The abnormalities evaluated included standard and intermediate risk: IGH rearrangements (IGH r), t(4;14), t(11;14), and high risk: t(14;20), t(14;16), del13q, del 17p, 1q21. Chi-square was used for statistical analysis. Due to smaller numbers, all M (Hispanic (H), Black (B), Asian (A) and Other (O)) were included into the same group for statistical analysis.
Results: 482 pts were eligible, 343 (71%) were W, 52 (10%) H, 50 (10%) B, 19 (3%) A, and 18 (3%) O. Median age was 65 years, 54% were male, and 26% ISS stage 3. There were no were no statistically significant differences in FISH abnormalities between the M. Overall W had more abnormalities in IGH r, t(4;14), t(11;14), t(14:20), 1q21 gain compared to M. Most notably W had more IGH r (39% *vs* 28%; p=0.019) and t(11;14) (20% *vs* 12%; p=0.024). There were no statistically significant differences between W and M in the high risk FISH abnormalities.

Table 1.

FISH, n (%)	W		H		B		A		O		M		p-values$
Total n=482	343		52		50		19		18		139		
IGH r	135	39%	16	30%	15	30%	4	21%	4	22%	39	28%	**<0.019***
t(4;14)	35	10%	4	7%	2	4%	2	10%	2	11%	10	7%	0.39
t(14;16)	21	6%	1	1%	5	10%	0	-	0	-	6	4%	0.43
t(11;14)	72	20%	7	13%	8	16%	2	10%	0	-	17	12%	**<0.024***
t(14;20)	6	1%	0	-	0	-	0	-	0	-	0	-	0.11
Del 13q	96	27%	16	30%	18	36%	2	10%	9	50%	45	18%	0.33
Del17p	159	45%	21	40%	22	44%	8	42%	11	61%	62	44%	0.72
1q21 gain	119	34%	12	23%	12	24%	7	36%	7	38%	38	27%	0.11

*$p-value compares W vs M. * means statistical significant (p-value<0.05)*

Summary/Conclusions: W had significant differences in FISH compared to M. W had more IGH r and t(11;14) than M, and there was no difference in high risk FISH abnormalities between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

E1289

POMALIDOMIDE ALONE OR IN COMBINATION WITH LOW DOSE DEXAMETHASONE AS MAINTENANCE FOLLOWING INDUCTION WITH POMALIDOMIDE AND LOW DOSE DEXAMETHASONE IN RELAPSED AND REFRACTORY MYELOMA (ALLG MM14)

A. Kalff[12,*], N. Kennedy[3], J. Reynolds[1], H. Quach[4], P. J. Ho[5], N. Horvath[6], P. Mollee[7], J. D'Rozario[8], K. Taylor[9], J. Estell[10], A. Spencer[12]
[1]Monash University, [2]Alfred Hospital, Melbourne, Australia, [3]Haematology Departmen,, Alfred Hospital, [4]St Vincents Hospital, Melbourne, [5]Royal Prince Alfred Hospital, Sydney, [6]Royal Adelaide Hospital, Adelaide, [7]Princess Alexandra Hospital, Brisbane, [8]The Canberra Hospital, Canberra, [9]Haematology & Oncology Clinics of Australia, Brisbane, [10]Concord Repatriation General Hospital, Sydney, Australia

Background: Whilst the addition of dexamethasone to upfront therapy with Immunomodulatory (IMiD®) agents is important to mediate rapid reduction in disease burden, preliminary findings suggest that the NK stimulatory effects of IMiD® compounds are best harnessed without the co-administration of dexamethasone, and may be especially effective in the setting of minimal disease burden (in the maintenance setting for example) when some inherent immune recovery has occurred. However this has yet to be confirmed in a prospective clinical trial.
Aims: To evaluate the effect of maintenance with POM alone (Arm 1) *versus* POM-LoDEX (Arm 2) on progression free survival (PFS), overall survival (OS), and kinetics of response (overall response rate (ORR)) in relapsed myeloma (MM) patients refractory to lenalidomide (R-LEN) demonstrating stable disease (SD) or better following salvage treatment with pomalidomide (POM) and low dose dexamethasone (LoDEX) induction.
Methods: Multicentre, open-label, randomized phase 2 study of relapsed R-LEN patients who had received>2 prior lines of therapy. POM 4mg days 1-21 (28 day cycle) was administered alone or in combination with LoDEX (40mg weekly) as maintenance following an induction with 4 cycles of POM and LoDEX. Treatment continued until toxicity or progression. Peripheral blood samples for immune studies were collected pre-induction and prior to cycles 1, 3, 6 and 10 of maintenance.
Results: 154 patients from 11 sites were enrolled on to the study (M:F 80:74), with a median age of 67 years (range 35-88). Median number of prior lines of therapy was 4.5 (2-14). All patients had failed LEN (100%), 127 (82.5%) were also refractory to bortezomib (double refractory) and 94 (61%) had received a prior autologous stem cell transplant. 72 (47%) patients achieved SD or better with POM-LoDEX induction and were randomised, 35 to POM (Arm 1) and to 37 to POM-LoDEX (Arm 2). After a median follow-up of 19 months, median PFS for all patients from study entry was 4.2m (IQR 2.1 – 8.6m). PFS for randomised patients (from time of randomisation) was 2.7m for POM (arm 1) *versus* 5.6 for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM *versus* POM-LoDEX (Figure 1.). Median OS for all patients from study entry was 13.2m (IQR 6.3-26.8m). For randomised patients, median OS (from time of randomisation) was 19m for POM (Arm 1) *versus* 13.7m for POM-LoDEX (Arm 2) (p=0.41). ORR (≥PR) for all patients was 45.5% [CR=5 (3.3%), VGPR=13 (8.4%), PR=52 (33.8%)]. Clinical benefit rate (CBR) (≥MR) was 55.2% [MR=15 (9.7%)].

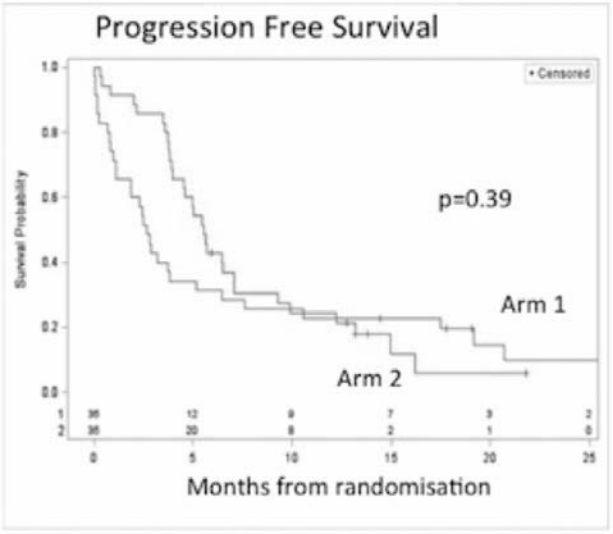

Figure 1.

Summary/Conclusions: In patients with relapsed myeloma, after initial disease control/debulking is achieved with POM - LoDEX, induction, maintenance with single agent POM may be more effective for sustaining disease control than continuation of POM-LoDEX. Correlative studies are currently underway to further investigate the immunological mechanisms behind this observation.

E1290

POMALIDOMID IS MORE EFFECTIVE IN REAL CLINICAL PRACTICE THAN IN RANDOMIZED TRIAL – AN OBSERVATIONAL STUDY OF THE CZECH MYELOMA GROUP

L. Pour[1,*], L. Brozova[2], I. Spicka[3], V. maisnar[4], J. Minarik[5], A. Jungova[6], E. Gregora[7], S. Sevcikova[8], P. Pavlicek[7], T. Jelinek[9], J. Radocha[4], M. Štork[10], R. Hajek[9]

[1]Departement Hematology and Oncology, University Hospital Brno, [2]Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, [3]First internal clinic, 1. medicine faculty Charles univesity prague, Praha, [4]University Hospital, Hradec Kralove, Hradec Kralova, [5]University hospital Olomouc, Olomouc, [6]University hospital Plzen, Plzen, [7]University Hospital Kralovske Vinohrady, Praha, Praha, [8]Masaryk university Brno, Brno, [9]University Hospital Ostrava and the Faculty of Medicine, Ostrava, [10]University hospital Brno, Brno, Czech Republic

Background: The combination of pomalidomide and low-dose dexamethasone (Pom-Dex) is a perspective option for patients with end-stage relapsed/refractory multiple myeloma (RRMM). We analyzed efficacy and toxicity of Pom-Dex in all patients from the Czech Republic treated from june 2013 to december 2016.
Methods: Patients were eligible if they had been diagnosed with RRMM and had failed at least two previous treatments with bortezomib and lenalidomide. They were treated with start dose of Pom (4mg/day on days 1-21, orally) plus low-dose dexamethasone (40mg/day on days 1, 8, 15, and 22, orally) until disease progression or unacceptable toxicity. We analyzed TTP and OS together with toxicity. Also, univariate Cox proportional hazards model for OS was done for standard risk factors. One hundred and twenty-two patients with median age of 67 treated with Pom-Dex were evaluated. Median follow-up was 8.7 months. Median of previous treatment lines was 4.
Results: Median TTP of Pom-Dex treatment was 7.1 months (95% CI 5.3-8.6). Median OS was 19.0 months (95% CI 13.2-25.8). The most common grade 3-4 adverse events were neutropenia in 44%, anemia in 22% and thrombocytopenie in 24% of patients. Grade 3-4 infection were observed in 10% of patients. Patients with ECOG worse than 2, B2microglobulin higher than 5, ISS stage 3, low hemoglobin, low platelet count and presenting extramedullary mass had worse OS according to univariate Cox proportional hazards model.
Summary/Conclusions: Our analyses show that Pom-Dex treatment of Czech RRMM patients is effective, well tolerated and had better results than the registration study. Performance status and tumor burden seem to be main prognostic factors according to our model. Thus, our suggestion for clinical practice is to start pomalidomide treatment as soon as possible in case of MM relapse.

E1291

UNDERSTANDING THE REAL-WORLD CLINICAL CHARACTERISTICS OF MULTIPLE MYELOMA PATIENTS IN EUROPE

T. Bacon[1,*], M. Gaudig[2], T. Ito[3], A. Hadfield[4], A. Rider[4]

[1]Janssen Health Economics & Market Access EMEA, Dublin, Ireland, [2]Janssen-Cilag, Neuss, Germany, [3]Janssen Health Economics & Market Access EMEA, High Wycombe, [4]Adelphi Real World, Bollington, United Kingdom

Background: Multiple myeloma is a heterogeneous disease that accounts for approximately 10% of all haematological malignancies. While European treatment guidelines exist for multiple myeloma, there is limited understanding about the characteristics of patients with multiple myeloma in Europe and how these characteristics vary by disease stage. Numerous patient and disease-related factors can have an impact on treatment choice. Data surrounding these factors would help to better characterise European patients and inform management and treatment practices in multiple myeloma.
Aims: The aim of the current study is to describe multiple myeloma patients from 5 European countries (France, Germany, Italy, Spain, and the UK) across the disease continuum.
Methods: Data were drawn from the Adelphi Real World Multiple Myeloma Disease-specific Programme (DSP), which was conducted across France, Germany, Italy, Spain, and the UK in Q1 2015. The Multiple Myeloma DSP is a real-world, cross-sectional survey that involves haematologists and haemato-oncologists who completed patient record forms for the next 8 multiple myeloma patients with whom they consulted. Study variables included patient demographics and background clinical information.
Results: A total of 262 physicians reported on 2,024 patients with multiple myeloma. Of these patients, 73.2% were receiving first-line treatment; the remaining 26.8% were receiving second-line treatment or later. The median age of multiple myeloma patients was 70 years, 58.4% were male, and most patients (88.5%) were white/Caucasian. Only 4.3% of patients had a family history of cancer. Patients had a mean height of 168.8 cm, a mean weight of 72.8 kg, and a mean body mass index of 25.5 kg/m^2. In terms of performance status, 79.8% of patients had an Eastern Cooperative Oncology Group (ECOG) status of 0 or 1, whereas 20.2% had an ECOG status of ≥2. While 12.9% of patients had smouldering myeloma, 47.5% of patients had advanced stage (stage III) disease. The most common symptoms experienced by patients were anaemia (31.0%), bone pain (32.4%), fatigue/weakness (28.4%), and kidney impairment or failure (12.6%). Furthermore, 34.6% of patients had bone complications at some point in time. Over half (51.1%) of patients had comorbidities; of these, 22.8% had hypertension and 12.5% had diabetes. Overall, 33.7% of patients were considered eligible for transplant. Variances in patient characteristics, both by country and by line of therapy, were observed.
Summary/Conclusions: Results from this analysis provide valuable insight into multiple myeloma patients in European countries. These findings can help to inform future treatment practices in Europe.

E1292

RAD REGIMEN AS INDUCTION BEFORE ASCT: OUTCOMES, SAFETY AND EFFECTS ON BONE METABOLISM AND ANGIOGENESIS; FINAL RESULTS OF A PHASE 2 STUDY OF THE GREEK MYELOMA STUDY GROUP

E. Terpos[1,*], E. Katodritou[2], A. Symeonidis[3], F. Zagouri[1], A. Gerofotis[2], G. Christopoulou[3], M. Gavriatopoulou[1], D. Christoulas[4], A. Kourakli[3], P. Konstantinidou[2], E. Kastritis[1], M.A. Dimopoulos[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, [2]Department of Hematology, Theagenion Cancer Hospital, Thessaloniki, [3]Department of Internal Medicine, Division of Hematology, University of Patras Medical School, Patras, [4]Department of Hematology, 251 General Air-Force Hospital, Athens, Greece

Background: There is limited published data on the efficacy and safety of the combination of lenalidomide, adriamycin and dexamethasone (RAD) as induction therapy for newly-diagnosed myeloma (NDMM) patients who are eligible for autologous transplantation (ASCT).
Aims: The primary endpoint of this phase 2 study was the assessment of overall response rate (ORR) after 4 cycles of RAD induction in NDMM patients who are eligible for ASCT. Secondary endpoints included safety, progression-free survival (PFS), time to progression (TTP) and overall survival (OS). Exploratory endpoints included: i) the yield of stem cell collection after RAD; ii) the effects of RAD on biochemical markers of bone metabolism: CTX, TRACP-5b, bone-alkaline phosphatase (bALP), P1NP, osteocalcin, soluble RANKL, osteoprotegerin (OPG) and dickkopf-1 (Dkk-1) and iii) the effects of RAD on angiogenic cytokines: angiopoietin- (Angp) 1 & -2, angiogenin (Ang), VEGF and bFGF.
Methods: Lenalidomide was administered at a dose of 25mg, po, daily, on days 1-21 of a 28-day cycle; dexamethasone was given at a dose of 40mg, po, on days 1, 8, 15, and 22, while adriamycin was administered as IV bolus infusion at a dose of 9mg/m^2, on days 1-4 of each cycle. Serum levels of the above markers of bone remodeling and angiogenesis were measured before and after 4 cycles of RAD, using ELISA methodology.
Results: Between November 2014 and February 2016, 45 patients (median age: 56 years) were enrolled. Osteolytic lesions were present in 33 (73%) patients, while 3 (6.6%) had hypercalcemia (>11mg/dl). All but one patient completed 4 cycles of RAD. Best response included one (2.2%) CR, 8 (17.8%) VGPRs, 21 (46.7%) PRs, for an ORR of 66.7%, while 14 (31%) patients had

stable disease and one progressed during the 4th cycle of treatment. After ASCT the ORR was 84.4%: 6 (13.3%) patients achieved CR, 13 (28.9%) VGPR and 19 (42.2%) PR. Adverse events of grade 3 or 4 included mainly anemia (4 patients, 9%), neutropenia (3, 6.6%) and febrile neutropenia (one patient). After a median follow-up of 19.1 months (range: 11.0-24.9), 11 patients have progressed and 4 died (all had achieved less than VGPR post-ASCT). The PFS, TTP and OS rates at 12 months were 88.6%, 88.6% and 100%, respectively. Forty (89%) patients had adequate stem cell collection post-RAD induction (mean±SD: 8.94±6.50 x10^6/kg CD34+ cells). Patients at baseline had elevated levels of CTX, TRACP-5b, sRANKL/OPG, Dkk-1, Ang, VEGF, VEGF-A, bFGF and reduced levels of Angp-1/Angp-2, bALP and P1NP compared to 30 healthy subjects of similar age and gender (p<0.01 for all comparisons). RAD therapy resulted in a reduction of circulating CTX (p=0.03), TRACP-5b (p<0.01), Ang (p=0.02), VEGF (p=0.01) and bFGF (p<0.01). Moreover, RAD increased serum levels of bALP (p=0.036), P1NP (p=0.028) and Ang-1/Ang-2 ratio (p=0.022). These alterations occurred irrespective of response, although patients who achieved at least VGPR tended to have more profound differences in the above parameters.

Summary/Conclusions: RAD resulted in successful induction for NDMM patients with an ORR of approximately 67% pre- and 84% post-ASCT. With a median follow-up of >1.5 year, the 12-month PFS rate and OS rates are high, as expected. RAD reduced bone resorption and increased bone formation; the latter has not been previously described with lenalidomide-based regimens. Furthermore, RAD reduced angiogenic cytokines and this supports the action of the regimen also through the disruption of the interactions between myeloma and stromal cells.

E1293

MULTIPLE MYELOMA IN THE REAL WORLD: HOW THERAPEUTIC LANDSCAPE HAS CHANGED IN THE LAST 15 YEARS

F. Cocito[1,*], V.V. Ferretti[1], S. Mangiacavalli[1], C.S. Cartia[1], M. Ganzetti[1], E. Fugazza[1], B. Landini[1], M. Catalano[1], M. Cazzola[1], A. Corso[1]
[1]Hematology, Policlinico S. Matteo, Pavia, Italy

Background: Therapeutic Multiple Myeloma (MM) scenario has completely changed in the last 30 years: conventional chemotherapy (CT) has been gradually abandoned and autologous stem cell transplantation(ASCT),proteasome inhibitors as Bortezomib (Bor) and immunomodulatory drugs as Thalidomide and Lenalidomide (Len) have become the new actors in MM treatment (Tx).
Aims: aim was to outline how the management of MM patients (pts) had changed in the last 15 years reporting the experience of a single center.
Methods: Overall survival(OS) was measured from disease onset to death for any cause or last follow-up. Progression free survival (PFS) was defined as the time from first-line tx to disease progression or last-follow-up. The effect of variables on OS and PFS was evaluated by log-rank test.

Table 1.

Median age	61.3yrs (27.9-86.5)
Age	
≤ 65yrs	63.5%(371/584)
65- 80yrs	32.7 %(191/584)
>80yrs	3.8 %(22/584)
Sex	
Female	46 % (270/584)
Male	54%(315/584)
ISS staging	
(available in 447/584 patients)	
ISS 1	25.7%
ISS2	2%
ISS3	72.3%
Asymptomatic MM	59/584(10.1 %)
Symptomatic MM	525/584(89.8%)
≤65yrs	337/525(64.2%)
>65yrs	188/525(35.8%)
CRAB at diagnosis	
bone lesions	63.6%
anemia (Hgb< 10 mg/dl)	23.7%
kidney failure (creatinine >2 mg/dl)	11.6%
hypercalcemia (calcium > 11.5 mg/dl)	7.7%

Results: We analyzed 584 MM pts diagnosed in our center from 2000 to 2015. Patients' characteristics are reported in Table1. Median number of therapy lines is 2 (1-9). Among pts ≤65 yrs, 242/371 (71.8%)received ASCT as 1st line tx. Patients >65 yrs were treated as follows: 16(8.5%) received ASCT,53(28.2%) VMP,21 (11.2%) MPT,45 (23.9%) MP and 53 (28.2%) other therapies. As 2nd line tx our pts received: 27 ASCT (8.9%), 115 Bor-based tx (38.1%), 48 Len-based tx (16%), 53 CT(17.5%) and 59 other therapies(19.5%). As 3rd line tx: 5 pts received ASCT (2.8%), 65 Bor-based tx (35.9%), 42 Len-based tx (23.2%), 39 CT (21.5%) and 30 other therapies (16.6%).The percentage of pts receiving a new drug in 1st line was 64% (338/525). This percentage was significantly different in pts treated before and after 2007 (42% *vs* 87%, p=0.001). Similar results were observed in 2nd line, 75% of pts treated before 2007 received a new drug and 90% after 2007(p=0.002). Median PFS in pts >65 *vs* ≤65 yrs was 1.7 *vs* 2.4 yrs (p<0.001); median PFS in pts ≤65 yrs receiving or not ASCT was 3.2 *vs* 1.9 yrs (p=0.001); of note, PFS was not different when considering pts undergoing to ASCT after a CT-based or a Bor-based induction(3 *vs* 2.5 yrs, p=0.2).Time to next treatment (TTNT) in pts receiving ASCT or not was 30.1 months (5-122.7) *vs* 10.3 months (0.2-70.5) (p<0.001) from 1st to 2nd line tx and 11.2 months (0.3-121.9) *vs* 6.3 months (1-41.6) from 2nd to 3rd line tx (p=0.026). The early mortality (within the first year) was 5.9% (31/525), in details only 1/258 of those eligible to ASCT (0.4%) and 30/267 of those not candidate to transplant (11.2%). When considering this last group before and after the 2007, we observed a significant higher incidence of early mortality in the first period [21 (17.2%) *vs* 9 (6.2%), p=0.006]. About new drugs toxicity: with Bor-based tx 30% of pts complaint neurological, 20% gastrointestinal and 18.2% hematologic toxicity; with Len-based tx 36.4% infective events and 28.9% hematologic toxicity. Median OS in pts ≤65 *vs* >65 yrs was 7 *vs* 4.8 yrs (p=0.001), of note considering pts ≤65 *vs* >65 yrs treated before 2007 median OS was 5.5 *vs* 3.1 yrs (p<0.001)and after 2007 median OS was not reached *vs* 7.5 yrs (p=0.034).
Summary/Conclusions: Our real life data show how MM therapeutic scenario have changed during the last 15 yrs. The tremendous improvement observed in this study was mainly evident in older pts with a strong reduction of early mortality and median OS reaching, in the second time frame after year 2007, 7.5 yrs. For younger pts ASCT confirmed to be of great benefit in term of TTNT and PFS. Thus, considering the real advantage of new drugs a palliative approach is not anymore justified even in very old pts.

E1294

CUL4A EXPRESSION AS A POTENTIAL PROGNOSTIC MARKER IN MULTIPLE MYELOMA PATIENTS TREATED WITH IMMUNOMODULATORY DRUGS

A. Malenda[1,*], J. Barankiewicz[1,2], A. Szumera-Ciećkiewicz[3], M. Prochorec-Sobieszek[3], K. Warzocha[1], P. Juszczyński[4], E. Lech-Marańda[1,2]
[1]Department of Hematology, Insititute of Hematology and Transfusion Medicine, [2]Department of Hematology and Transfusion Medicine, Centre of Postgraduate Medical Education, [3]Department of Diagnostic Hematology, [4]Department of Experimental Hematology, Insititute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Despite the clinical effectiveness of immunomodulatory drugs (IMiDs) in multiple myeloma (MM), neither their mechanisms of action nor the biomarkers that could identify patients who would benefit from IMiDs treatment are yet known. While the identification of the IMiDs action via cereblon (CRBN), Ikaros (IKZF1) and Aiolos (IKZF3) was a milestone, the role of other pathways including CRBN and E3 ubiquitin ligase complex proteins (CUL4A, DDB1, Roc1) are not fully understood so far.
Aims: The aim of this study was to: 1) evaluate CUL4A, IKZF1, IKZF3, MUM1 and IRF4 expression in bone marrow trephine biopsies obtained from multiple myeloma patients before treatment with thalidomide, 2) analyze the associations between the expression of these proteins and clinical characteristics and outcomes.
Methods: IHC staining for CUL4A, IKZF1, IKZF3, IRF4 and MYC expressions was performed in trephine biopsies obtained from 25 patients with multiple myeloma before the treatment initiation. The patients (20 females, 5 males, median age 68 years) were treated with thalidomide based regimens as a first-line treatment. The patterns of proteins' expression were scored independently by two hematopathologists on a semi-quantitative scale and the cutoff was defined as ≥ 30% positive cells. Associations between studied proteins' expression and clinical parameters were assessed using Fisher's Exact Test for categorical variables and Mann-Whitney-Wilcoxon Test U for continuous variables. Survival (PFS and OS) were estimated using the Kaplan-Meier method and compared using the log-rank test.
Results: Prior to treatment with thalidomide, 13 patients (52%) showed high expression (≥ 30%) of CUL4A protein. No associations between expression of CUL4A and other proteins were seen. Patients with high CUL4A expression more often presented low disease stage according to Durie-Salmon classification (P=0.02), beta-2-microglobulin level within normal ranges (P=0.07) and higher median platelet count (P=0.003) compared to patients with low CUL4A expression. Moreover, patients with high CUL4A expression before treatment showed longer PFS compared to those with low CUL4A expression (P= 0.03). Additionally, a significant association between high Aiolos expression and higher median of CD138+ cells in bone marrow was observed (P=0,01) compared to low Aiolos expression, however no other associations with clinical course of MM patients were seen. No associations between IKZF1, IKZF3, IRF4, MYC expression and patients' characteristics or outcome were revealed.

Summary/Conclusions: In conclusion, our results suggest that CUL4A expression could serve as prognostic marker for patients assigned to IMiDs containing regimens. Further analysis of the expression of other E3 ligase complex proteins in a larger patient cohort is in progress.

MAINTENANCE THERAPY WITH BORTEZOMIB IN PATIENTS WITH MULTIPLE MYELOMA (MM) AFTER ASCT AND MINIMAL RESIDUAL DISEASE (MRD)

M. Solovev[1,*], L. Mendeleeva[1], O. Pokrovskaya[1], E. Gemdzhian[2], I. Galtseva[3], J. Davydova[3], M. Firsova[1], M. Nareyko[1], T. Abramova[4], V. Savchenko[4]
[1]Dept. of High-Dose Chemotherapy of Paraproteinemic Hemoblastosis, [2]Biostatistics Laboratory, [3]Immunophenotyping of Blood Cells and Bone Marrow Laboratory, [4]Research Center for Hematology, Moscow, Russian Federation

Background: MRD-negativity status in patients with MM after autologous stem cell transplantation (ASCT) directly correlates with higher Relapse-Free Survival. It remains unclear whereas these patients should all receive maintenance therapy with it's toxicity and cost.
Aims: To assess efficacy of maintenance therapy with Bortezomib in patients with MM, who have achieved complete remission after ASCT with MRD positive and negative status.
Methods: From January 2014 to February 2016 52 patients with MM (19 male and 33 female) ages from 24 to 66 years (median 54 years) who have achieved complete remission after ASCT were randomized for a year-long maintenance therapy with Bortezomib. On 100th day after ASCT and after completion of maintenance therapy samples bone marrow from all patients were assessed using 6-color Flow Cytometry to detect MRD. We chose Relapse-Free Survival (RFS) as the indicator of maintenance therapy efficacy. Kaplan-Meier survival curves were compared using log-rank test. Statistical analysis was performed using SAS 9.4.

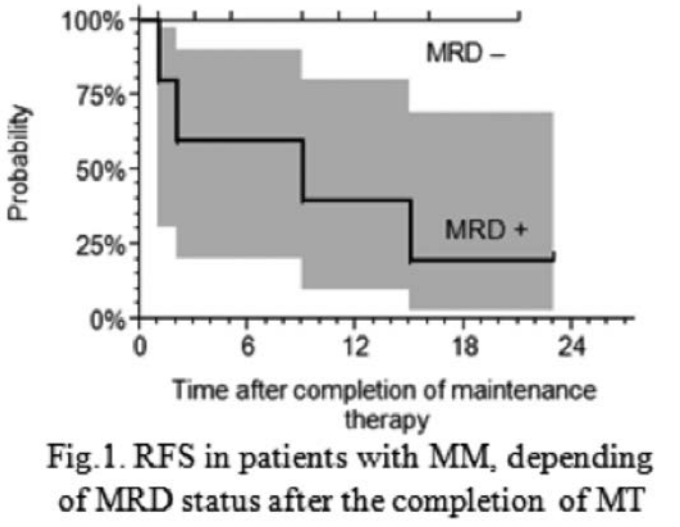

Fig.1. RFS in patients with MM, depending of MRD status after the completion of MT

Figure 1.

Results: 2-year Relapse-Free Survival in patients with MRD-negative status after ASCT was higher (p=0.05) than that in MRD-positive patients - 52,9% (95% CI: 35,5–70,5%) *vs* 37,2% (95% CI: 25,4–49,3%). The MRD-positivity significantly increases the risk of relapse (HR=1,7; 95% CI: 1,2–3,4; p=0,05). Two year cumulative probability of relapse after ASCT in patients with MRD-negative status, who had (n=15) and hadn't received (n=10) maintenance therapy with Bortezomib was not different (p=0,58). Average time of relapse in MRD-positive patients who received maintenance therapy with Bortezomib was 5 months longer than in the group of patients without maintenance therapy - 17,3 months *vs* 12,3 months. In the group of MRD-positive patients who did not completed maintenance therapy, relapse was diagnosed in 6 patients. After the end of the treatment 42% of MRD-positive patients achieved MRD-negative status. RFS in this group of patients was significantly higher than in the group of treated MRD-positive patients who retained that status after maintenance therapy (MT) - 100% *vs* 20% (p=0,02, Fig.1).
Summary/Conclusions: In cases when MRD-negative status was achieved after ASCT, maintenance therapy does not increase the RFS. In comparison – patients with positive MRD status after ASCT require maintenance therapy to improve their survival rate.

E1296

LONG-TERM OUTCOME OF MULTIPLE MYELOMA (MM) PATIENTS TREATED UP-FRONT WITH SINGLE OR TANDEM AUTOLOGUS STEM CELL TRANSPLANTATION (ASCT) - SINGLE CENTRE EXPERIENCE WITH 334 PATIENTS

J. Batinic[1,2,*], S. Basic-Kinda[1], B. Dreta[1], I. Hude[1], A. Ostojic[1], D. Sertic[1], R. Serventi-Seiwerth[1], P. Roncevic[1], I. Bojanic[3], K. Gjadrov-Kuvezdic[4], K. Dubravcic[5], I. Ilic[4], I. Aurer[1,2], D. Nemet[1,2]
[1]Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, [2]Medical School, University of Zagreb, [3]Department of Transfusiology, [4]Department of Pathology and Cytology, [5]Department of Laboratory Diagnostics, University Hospital Centre Zagreb, Zagreb, Croatia

Background: ASCT after induction treatment has been standard of care for MM for almost 30 years. Some centers routinely perform two transplantation up-front (so-called tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.
Aims: To describe long-term outcomes of MM patients treated with ASCT (single and tandem) in a single centre. alled tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.
Methods: This was a retrospective analysis of outcomes of 334 MM patients who underwent 470 ASCT procedures at our center between 1993 and 2014. During that period treatment policies changed from single to tandem to salvage second ASCT, as data from different clinical studies became available.
Results: 296 patients received VAD (vincristine, doxorubicin, dexamethasone) as induction therapy and 38 regimens based on immunomodulatory drugs or proteasome inhibitors. All received high-dose melphalan for pretransplant conditioning, 32 in combination with total body irradiation. Tandem ASCT (defined as second transplantation performed within 6 months after the first) was performed in 136 patients, single ASCT in 168 and salvage second (after relapse/progression) in 30 patients. Transplant related mortality was 1.5%. Median follow up is 70 months (range 4 – 238). Median overall survival (OS) for the entire group is 123 months and median progression free survival (PFS) 40 months. Tandem ASCT in comparison to single and second salvage transplantation resulted in superior OS (203 *vs* 86 *vs* 68 months respectively, p<0.0001) and PFS (60 *vs* 38. *vs* 25 months respectively, p<0.0001) (figure). Thirteen percent of patients who underwent tandem ASCT are alive and progression-free more than 10 years after the procedure. Fourteen patients developed secondary malignancies.

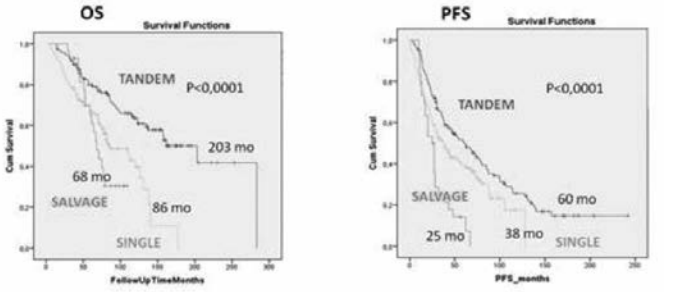

Figure 1.

Summary/Conclusions: Our results suggest that tandem ASCT is a very effective treatment modality that can partially substitute for the absence of expensive novel agents with low long-term and lethal toxicities. Tandem ASCT seems to result in superior OS and PFS in comparison to single or salvage second ASCT. More than 10% of patients treated with tandem ASCT experience very prolonged PFS.

E1297

EXTRAMEDULLARY DISEASE IN MULTIPLE MYELOMA PATIENTS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION: CLINICAL IMPACT IN DIAGNOSIS, TREATMENT AND OUTCOME

A. Roque[1,2,*], A.L. Pinto[1], E. Cortesão[1,2], A. I. Espadana[1], A.B. Sarmento-Ribeiro[12], C. Geraldes[12], L. Ribeiro[1]
[1]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Extramedullary disease (EMD) is defined as an infiltrate of clonal plasma cells outside of the bone marrow. The presence of EMD in multiple myeloma (MM) patients (pts) at diagnosis is a relatively uncommon presentation and accounts for about 13% (6-20%) of MM pts. Although several studies

showed an association of EMD with other adverse prognosis factors and unfavourable outcomes, reports evaluating EMD role in pts undergoing autologous hematopoietic stem cell transplantation (aHSCT) are scarce.
Aims: We aimed to evaluate the clinical and laboratorial characteristics of pts with EMD as well as its impact in outcomes of MM pts submitted to aHSCT (response to treatment, overall survival [OS] and progression free-survival [PFS]).
Methods: We analysed 155 MM pts submitted to aHSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016).
Results: The median age of the cohort was 58 years (27-69), with 58% of males, and the most common subtype was IgGκ (45%). In our cohort, 46 pts (29.7%) presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p<0.001; 95%CI 0.22-0.37). The more common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38 *vs* 18%; p=0.012) and in pts with bone disease at diagnosis (45 *vs* 13%; p<0.001). Surprisingly, it was more commonly observed in pts with lower International Staging System scores (I and II *vs* III) (82 *vs* 64%; p=0.022) and without anaemia at diagnosis (28 *vs* 11%; p=0.023). No other significant differences in characteristics at diagnosis were found between pts with and without EMD. Pts with EMD achieved lower complete response/ very good partial response (CR/VGPR) proportions previously to aHSCT (30.4 *vs* 53.2%; p=0.009), as well as at 100 days after aHSCT (D100) (41.3 *vs* 59.6%; p=0.037). However, no differences were found concerning refractoriness to first line therapy or proteasome inhibitor (PI) treatment, despite EMD pts received a higher mean number of therapeutic lines previously to aTPH (1.7 *vs* 1.4; p=0.025). After a median follow-up of 46.6 months, the median OS was not reached for global cohort and both groups, and there was no difference between them (p=NS). The median PFS was 51.3 months for global cohort, with no differences seen between pts with and without EMD (50.2 *vs* 54.1; p=NS). Pts with EMD treated with a PI (57%) presented a higher OS (NR *vs* 55.2 months, p=0.04), but with no impact in PFS (p=NS), and there were no differences concerning radiotherapy treatment (72%) or thalidomide maintenance after aHSCT (32%) (p=NS).
Summary/Conclusions: In our cohort, EMD prevalence was significantly higher than usually described in the literature. This observation was probably associated with a more carefully surveillance of EMD in aHSCT candidates. EMD was associated with a lower proportion of CR/VGPR previous to aHSCT and at D100 evaluation, even after a higher number of therapeutic lines, although we failed to demonstrate that EMD was an independent prognosis factor for PFS and OS. PI seem also to be the best first-line therapeutic approach for EMD pts. In conclusion, our study suggests that EMD is underdiagnosed in MM pts. It is necessary to achieve a better knowledge of the physiopathology of EMD, in order to define better treatment options that may overcome its negative impact in therapeutic response.

E1298

DIFFERENCES IN PATIENT AND DISEASE CHARACTERISTICS OBSERVED AT INITIATION OF FIRST-LINE AND INITIATION OF SECOND-LINE TREATMENT IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA IN THE CZECH REPUBLIC

V. Maisnar[1,2,*], Z. Szabo[3], W. Bouwmeester[4], L. DeCosta[5], L. Pour[6,7], E. Gregora[8], J. Minařík[9,10], S. Gonzalez-McQuire[3], R. Hájek[11,12]
[1]Faculty of Medicine, Charles University Hospital, [2]4th Department of Medicine – Haematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic, [3]Amgen (Europe) GmbH, Zug, Switzerland, [4]Pharmerit International, Rotterdam, Netherlands, [5]Amgen Ltd, Uxbridge, United Kingdom, [6]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, [7]Faculty of Medicine, Masaryk University, Brno, [8]Department of Internal Medicine and Hematology, University Hospital Kralovske Vinohrady, Prague, [9]Department of Hemato-Oncology, University Hospital Olomouc and Palacky University Olomouc, [10] Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, [11]Department of Haemato-oncology, University Hospital Ostrava, [12]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic

Background: Tools such as the International Staging System (ISS) and the revised ISS (R-ISS) are used to stratify risk of death in patients newly diagnosed with multiple myeloma (MM), enabling assessment of survival expectations. These tools are based on factors measured at diagnosis only; understanding the role of these factors at relapse is less clear. Patient characteristics change between first-line (1L) and second-line (2L) treatment. Predicting survival using tools that rely on patient characteristics measured at diagnosis only may, therefore, become less relevant than other tools that consider factors measured at relapse. The Registry of Monoclonal Gammopathies (RMG) is a large hematological disease registry, collecting data from patients in the Czech Republic and Slovakia. Data from the RMG can be used to explore real-world characteristics of patients with MM throughout their disease course.
Aims: To explore how key characteristics of patients with relapsed MM evolve between initiation of 1L treatment and initiation of 2L treatment to better understand drivers of disease progression and death.
Methods: This non-interventional, observational, retrospective study used data collected prospectively from Czech patient charts available in the RMG. Adults (≥18 years old) initiating 1L treatment for MM between May 2007 and April 2016 were included (N=3027); those with smoldering MM were excluded. Patient and disease characteristics were extracted at initiation of 1L and of 2L treatment. Repeated measurements were available only for those who initiated 1L and 2L treatment (1L+2L group; N=1418); patients who did not start 2L treatment may have been in remission, lost to follow-up or had died.
Results: Patient and disease characteristics are summarized in the table (all patients starting 1L and those who started 1L+2L). In general, for patients who received 1L+2L treatment, their health status improved between initiation of 1L and of 2L treatment. At 2L, patients tended to have a lower ISS stage (re-measured at 2L) than when they started 1L (stage I at 1L: 26.6%; at 2L: 41.1%). Similarly, the proportion of patients with R-ISS stage III disease was lower at start of 2L (24.6%) than at start of 1L (31.1%) treatment. Eastern Cooperative Oncology Group performance status scores were also better for patients when they started 2L than when they started 1L treatment (stage 3–4 at 1L: 8.7%; at 2L: 5.5%). Laboratory measurements indicated that patients were in better health at the start of 2L treatment than at initiation of 1L treatment: median M protein levels decreased from 31.2 g/L at 1L to 17.7 g/L at 2L, and elevated calcium and creatinine levels were less common at 2L than at 1L. Median lactate dehydrogenase levels were slightly elevated at start of 2L *vs* start of 1L treatment (184.4 U/L *vs* 206.6 U/L).

Table 1.

	Characteristics at:	Initiation of 1L treatment		Initiation of 2L treatment
	Patient group:	1L (N=3027)	1L+2L (N=1418)	1L+2L (N=1418)

	>173	540 (23.2%)	291 (20.8%)	166 (13.8%)
	NA	699	20	213
	Median M protein level, g/L (5th–95th percentile)	25.2 (0.0–68.8)[b]	31.2 (0.0–72.2)	17.7 (0.0–51.5)
	NA	126	62	261

Data shown are n (%), unless otherwise stated.
[a]Standard risk: negative for del(17p), t(4;14) and t(14;16); high risk: positive for del(17p), t(4;14) or t(14;16).
[b]Measured at diagnosis.
1L, first line; 2L, second line; ECOG PS, Eastern Cooperative Oncology Group performance status; ISS, International Staging System; NA, not available.

Summary/Conclusions: Patient health was better at initiation of 2L treatment than at initiation of 1L treatment. At relapse, patients are likely to be closely monitored and are able to initiate the next treatment line while in relatively good health; at initiation of 1L, patients may have experienced deterioration in health which could have triggered their diagnosis. These findings illustrate how patient characteristics change over time and indicate that factors influencing survival may evolve; therefore, restaging patients at relapse may be beneficial and could contribute to improved predictive tools that can better define survival estimations at first relapse by considering patients' experiences at 1L.

E1299

AN EARLY GOOD RESPONSE AFTER BORTEZOMIB-BASED INDUCTION REGIMENS REPRESENTS A SIGNIFICANT PREDICTOR FOR IMPROVED PFS IN NDMM PATIENTS

G. Rivoli[1,*], M. Cea[1], S. Aquino[2], A. Dego[1], N. Di Felice[1], N. Bisso[1], D. Avenoso[1], R. M. Lemoli[1], M. Gobbi[1], L. Canepa[1]
[1]Clinica Ematologica, [2]Ematologia 1, IRCCS San Martino IST, Genova, Italy

Background: Introduction of triplets-based induction regimens containing proteasome inhibitors (PIs) in clinical practice have led to higher response rates and prolonged life expectancy in newly diagnosed multiple myeloma (NDMM)

patients. Different studies have linked complete response (CR) with better PFS (progression free survival), but not always with prolonged overall survival (OS), most likely due to the impact of novel agents in the management of relapsed-refractory patients. Overall, these observations suggest PFS as a more reliable predictor of clinical outcome. Also, the biological aggressiveness is emerging as a pivotal disease characteristic which affects clinical behavior and response to therapy. In this context, little is known about the association of response kinetic with survival outcomes.

Aims: In order to evaluate whether early achievement of a good quality response impacts on outcome, we retrospectively analyzed 87 NDMM patients treated at our institution with bortezomib containing regimens (BRs).

Methods: From 2004 to 2016, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible to ASCT were included in the study; patients undergoing ASCT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9). PFS was defined according to IMWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del17p, del13q, t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

Results: PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p= 0.036, median PFS 44.7 *vs* 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR *vs* non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

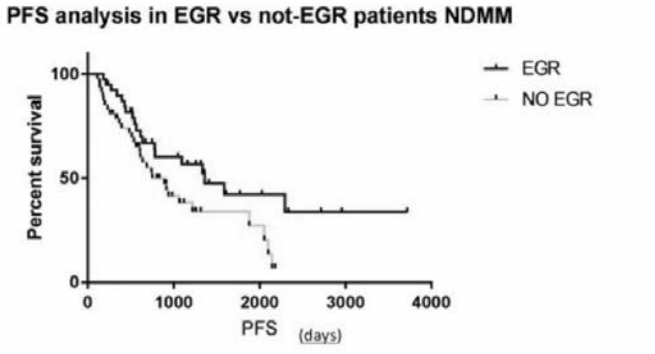

Figure 1.

Summary/Conclusions: Overall, our data demonstrate a significant impact of EGR on PFS in NDMM patients after BRs, irrespective of median age at diagnosis. In presence of high cytogenetic risk EGR is associated with prolonged PFS, although not significantly. Ongoing analysis on larger cohort of high risk patients will confirm the impact of EGR on PFS also in this group of patients. Based on our data kinetic of response, deriving from EGR assessment, may provide information on both disease aggressiveness as well as clinical outcome, thus representing a novel, surrogate marker for an early survival analysis, with favorable cost-effectiveness characteristics. In summary biological and clinical information deriving from EGR analysis combined with cytogenetic risk evaluation and patient-related (age, comorbidities) characteristics, may represent a useful tool to make clinical decisions. Further prospective evaluations are needed to include this marker in clinical practice.

E1300

RELATIVE PROGRESSION-FREE SURVIVAL OVER TIME OF NOVEL TRIPLET REGIMENS FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA

K. Betts[1], C. Chen[2], M. Zichlin[1], A. Brun[2], J. Signorovitch[1], D. Makenbaeva[2,*]
[1]Analysis Group, Inc., Boston, MA, [2]Bristol-Myers Squibb, Inc., Plainsboro, NJ, United States

Background: In combination with lenalidomide (REVLIMID®, R) and dexamethasone (d), elotuzumab (EMPLICITI™, E), carfilzomib (KYPROLIS®, K), and ixazomib (NINLARO®, N) were recently approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In randomized controlled trials, all three drugs showed a significant relative reduction in the risk of disease progression or death as compared to patients who received Rd. To date, there have been no head-to-head trials comparing ERd, KRd, and/or NRd.

Aims: To describe the time-specific progression-free survival (PFS) based on published Kaplan-Meier PFS curves for ERd, KRd, and NRd relative to Rd.

Methods: Individual patient-level data (IPD) were reconstructed from the published Kaplan-Meier PFS curves from the ELOQUENT-2 (ERd), ASPIRE (KRd), and TOURMALINE-MM1(NRd) randomized, controlled, Phase III trials using digitization software and the methods described by Guyot, et. al. Using the reconstructed IPD, Kaplan-Meier survival curves were estimated for each arm within each trial. PFS curves were digitized by two independent researchers and the reconstructed curves were overlaid with the published data to validate the IPD. In each trial, the relative PFS benefit over time was calculated as the difference in the Kaplan-Meier PFS estimate of each triplet regimen and the Kaplan-Meier PFS estimate of Rd divided by the Kaplan-Meier PFS estimate of Rd: $rPFS(t)=[S_{XRd}(t) - S_{Rd}(t)] / S_{Rd}(t)$. Where S(t) denotes the Kaplan-Meier PFS estimate at time t, and X denotes E, K, or N, respectively.

Results: IPD from the three randomized controlled trials was successfully reconstructed and validated. Numerically, ERd had the highest relative PFS over the initial 10 months of treatment and showed sustained benefit from month 24 onwards (**Figure 1**). At 12 months, the relative PFS benefit was 17.9% for ERd, 21.7% for KRd, and 9.7% for NRd. At 24 months, the relative PFS benefit was 45.1% for ERd, 34.3% for KRd and 24.1% for NRd. At 36 months, the relative PFS benefit was 39.9% for ERd and 19.1% for KRd. ERd had a higher relative PFS than NRd for almost the entirety of RRMM treatment. At the end of data availability, NRd and KRd showed no additional PFS benefit relative to Rd, while ERd showed a sustained benefit through 40 months. Data will be updated for the conference, where available.

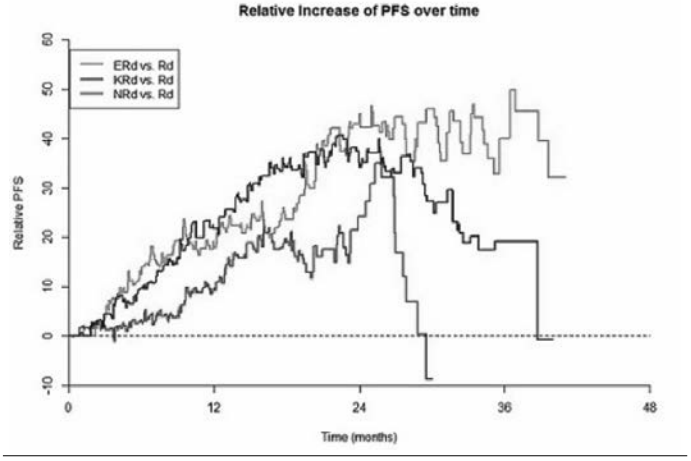

Figure 1.

Summary/Conclusions: For the treatment for RRMM, ERd showed an early and sustained benefit in relative PFS which was maintained through 40 months. KRd and NRd showed initial benefits which faded by the end of data availability.

E1301

POMALIDOMIDE WITH LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A PROSPECTIVE ANALYSIS IN A POPULATION-BASED REGISTRY

R. Wester[1,*], A. Dinmohamed[1,2,3], P. Sonneveld[1], A. Broijl[1], N. Blijlevens[4]
[1]Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam, [2]Department of Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [3]Department of Public Health, Erasmus University Medical Center, Rotterdam, [4]Department of Hematology, Radboud umc, Nijmegen, Netherlands

Background: Patients with relapsed and/or refractory multiple myeloma (RRMM) have limited treatment options and a poor prognosis. Previous trials showed that pomalidomide combined with low-dose dexamethasone is effective in these patients with improvement in response and survival. These studies led to the approval of pomalidomide as third line treatment in patients with RRMM.

Aims: A prospective analysis in a population-based registry was conducted to assess response and survival in patients with RRMM treated with a pomalidomide-based regimen. Also, we defined subgroups who benefit most of this treatment regimen.

Methods: Patients were eligible for pomalidomide if they received ≥2 prior lines of therapy including bortezomib, lenalidomide and alkylator therapy and developed progressive disease on their last therapy. This is a prospective analysis of patients registered at the nationwide Netherlands Cancer Registry. Treatment consisted of 4mg pomalidomide, day 1-21, combined with corticosteroids. Treatment was discontinued in case of progressive disease or unacceptable toxicity. Primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), toxicity, response per risk group (based on cytogenetics and ISS at initial diagnosis) and response per age group (≤65 *vs* >65 years).

Results: A total of 82 patients (median age 68 years [range: 43-88]) were included in this analysis. CRAB criteria included anemia in 23 patients (28%), renal insufficiency in 8 (9.8%), hypercalcemia in 13 (16%) and bone lesions in 54 (66%). Median time from diagnosis to start pomalidomide was 5.75 years [range: 0.8-18.4], median number of treatment cycles was 3 [range: 1-17]. At time of analysis 59 patients had stopped pomalidomide treatment: 24 patients had progressive disease, 10 had unacceptable toxicity, 6 patients were refractory, 4 patients died during treatment and 15 patients stopped due to various other reasons. Grade ≥3 hematological adverse events occurred in 11% of patients, 4% had neutropenic fever. Grade ≥3 non-hematological toxicities occurred in 57% of patients, including infection in 22%, gastrointestinal disorders in 5% and renal disorders in 5%. Of 69 patients evaluable for response ORR was 41%, with a partial response (PR) rate and a very good partial response (VGPR) rate of 36% and 4% respectively. Response based on age was not significantly different (p=0.426). Median PFS for all patients was 3.8 months (95% confidence interval [CI] 2.3-6.6). Patients >65 years had a longer PFS of 5.7 months (95% CI 2.3-8.0) *versus* 2.8 months (95% CI 1.9-6.6) in patients ≤65, however, this was not statistically significant (p=0.427) (figure 1). For patients achieving ≥PR, median PFS was 9.6 months (95% CI 5.7-not reached (NR)). Median PFS in patients diagnosed more than ten years prior to initiation of pomalidomide treatment was 9.6 months (95% CI 1.8-NR), as compared to 2.2 months (95% CI 1.9-6.6) among patients treated within 5 years after diagnosis (p=0.05). Data about previous treatment, ISS stage, cytogenetics at diagnosis and an update of OS will be presented at EHA.

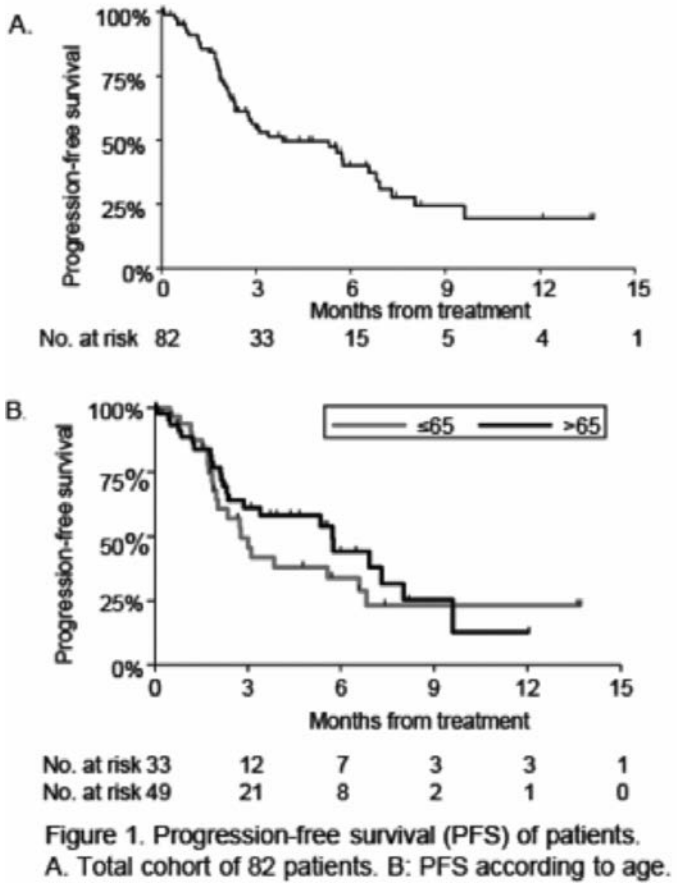

Figure 1. Progression-free survival (PFS) of patients. A. Total cohort of 82 patients. B: PFS according to age.

Figure 1.

Summary/Conclusions: In this analysis the experience in clinical practice of patients with RRMM treated with a pomalidomide-based regimen is reported. These data support results shown in clinical trials. Preliminary data presented here suggest that older patients and patients with a long interval between initial diagnosis and pomalidomide treatment (indicating a less aggressive multiple myeloma) may benefit from this treatment.

E1302

INVOLVED/UNINVOLVED HEAVY/LIGHT CHAIN INDEX CAN PREDICT PROGRESSION IN MULTIPLE MYELOMA PATIENTS AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM TRANSPLANT. PRELIMINARY EXPERIENCE

M. Espiño Martinez[1,*], A. Arteche Lopez[2], A. Arriero[3], C. Muñoz-Calleja[4], A. Alegre Amor[3], M.J. Blanchard Rodríguez[5], F.J. López Jiménez[5], L.M. Villar[1]
[1]Immunology, University Hospital Ramon y Cajal, [2]Clinical Analisis, [3]Haematology, [4]Immunology, University Hospital La Princesa, [5]Haematology, University Hospital Ramon y Cajal, Madrid, Spain

Background: High-dose therapy followed by autologous peripheral blood stem transplant (APBSCT) has demonstrated to improve overall survival and progression free survival with a high complete remission rate in multiple myeloma (MM) patients. However most patients eventually present progression or relapse (P/R). Detection of P/R is mainly based on a significant increase of monoclonal protein (MC) or free light chains (sFLC). The identification of new biomarkers to early predict P/R might be clinically useful for an anticipated therapy.
Aims: The aim of our study was to evaluate the potential role of the Involved/Uninvolved Heavy/Light Chain index (I/Ui) in this setting.
Methods: We prospectively followed 44 MM transplanted patients: 19 with IgG-kappa isotype, 11 with IgG lambda, 9 with IgA-kappa and 5 with IgA-lambda. They were followed for 29.0±3.8 months (mean±standard error (SE)). Serial serum samples from each MM patients were collected periodically after APBSCT. Relapse or progression was defined according IMWG criteria. To identify factors that predict disease progression in MM transplanted patients, we studied heavy/light chains (HLC) pair quantification, sFLC and total immunoglobulins levels in serial serum samples collected during the follow-up. Involved/uninvolved index (I/Ui) was calculated using the monoclonal chain (Involved) as numerator and the polyclonal chain of the same class (Uninvolved) as denominator. The HLC ratio (rHLC) was calculated as IgGκ/IgGλ or IgAκ/IgAλ with normal reference ranges established in 1.3-3.7 for IgG and 0.7-2.2 for IgA.
Results: In IgG MM patients, values of I/Ui were significantly increased in pre-relapse compared to basal samples (8.49±4.01 *vs* 2.23±0.67 p=0.012). By contrast, this index remained stable along follow-up in patients in complete remission (CR) or with a partial response (PR). However, the later showed higher values of I/Ui ratio, suggesting that the presence of an M-component induces a moderate immunosuppression of the uninvolved chain of the monoclonal isotype. Regarding IgA MM, we established a cut-off value of 2.0 for I/Ui that allowed the discrimination of patients at high risk of early progression (values above 2.0) from those in CR, whose levels of I/Ui are always below 2.0 (p=0.02).
Summary/Conclusions: Our results show that HLC-pair measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.

E1303

MULTIPLE MYELOMA IMMUNOPHENOTYPIC REMISSION IS A SIGNIFICANT PREDICTOR OF PROGRESSION FREE SURVIVAL AFTER FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION - PILOT STUDY

K. Beranova[1,*], J. Radocha[1], O. Soucek[2], K. Machalkova[1], J. Hanousek[1], P. Zak[1], V. Maisnar[1]
[1]IV. interni hematologicka klinika, [2]Institute of Clinical Immunology and Allergology, Fakultni nemocnice Hradec Kralove, Hradec Kralove, Czech Republic

Background: Minimal residual disease in multiple myeloma assesed by multiparameter flow cytometry has become an increasingly important predictor of progression-free survival (PFS).
Aims: Our primary endpoint was to evaluate PFS in myeloma patients after stem cell transplantation who reached immunophenotypic CR (iCR) *versus* those who have not.

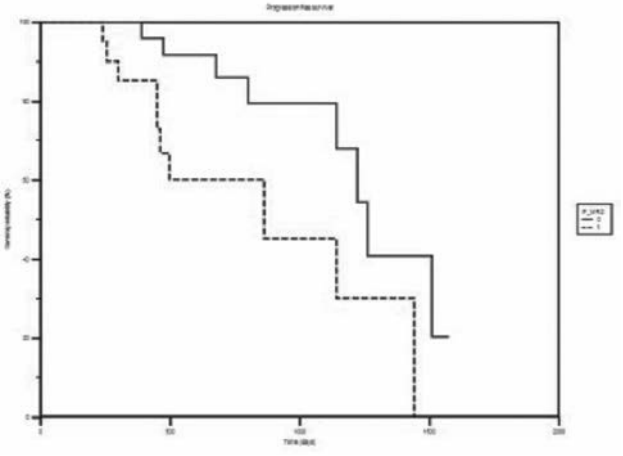

Figure 1.

Methods: We prospectively evaluated prognostic importance of minimal residual disease detection by multiparameter flow cytometry (MFC) in multiple

myeloma patients who underwent autologous stem cell transplantation from January 2014 until December 2016. All patients were uniformly treated with bortezomib based induction therapy followed by high dose chemotherapy (Melphalan 200mg/m^2) and autologous stem cell transplantation. Minimal residual disease (MRD) status was determined by 8-colour MFC 1 month after autologous transplantation from bone marrow aspirate in all patients who achieved at least conventional VGPR or CR.
Results: We identified 56 patients who fulfilled the above mentioned criteria. 30 were males and 26 females, median age was 61. 62.5% of patients (35/56 patients) achieved iCR, 37.5% of patients (21/56) did not. Median follow up of the cohort was 19 months (6-59). 32.1% of patients (18/56) relapsed during the follow-up period, 16.1% of patients (9/56) died. 22.9% (8/35 patients) in iCR and 47.6% (10/21 patients) not in iCR relapsed during the follow up. Patients in iCR showed significantly longer PFS with median 42 months than those in less than iCR with PFS median 29 months (p=0.0196, log-rank test). This was reflected by decreased hazard ratio of relapse (0.3565) for iCR group.
Summary/Conclusions: Achieving immunophenotypic CR is clearly associated with longer progression free survival compared to conventional CR. Reaching iCR should be a goal of myeloma treatment.

E1304

REGULATION OF NORMAL AND MONOCLONAL IMMUNOGLOBULIN SECRETION BY CYTOKINES (S- SYNDECAN-1, BLYS & TGF-BETA-1) IN PATIENTS WITH IG-SECRETING B-CELL DISORDERS AT PRESENTATION. PROGNOSTIC IMPLICATIONS

E. Koulieris[1], P. Papaioannou[1,*], E. Nikolaou[1], K. Sarris[1], D. Maltezas[1], S. Harding[2], N. Kafassi[3], K. Tsalimalma[3], K. Bitsani[1], T. Tzenou[1], V. Bartzi[1], P. Petsa[1], S. Kotsanti[1], A. Koudouna[1], E. Kastritis[4], S. Sachanas[5], M. Angelopoulou[1], G. Pangalis[5], E. Terpos[4], P. Sfikakis[1], M. Dimopoulos[4], P. Panayiotidis[1], M.-C. Kyrtsonis[1]
[1]Hematology Section - 1st Department Of Propaedeutic Internal Medicine, Laikon General Hospital, Athens, Greece, [2]Binding Site Ltd, Birmingham, United Kingdom, [3]Immunology Laboratory, Laikon General Hospital, [4]Therapeutic Clinic, Alexandra's Hospital, [5]Hematology Clinic, Medical Center Psychico, Athens, Greece

Background: The most common neoplastic lymphoproliferative diseases that secrete paraprotein are multiple myeloma (MM), Waldenstrom's Macroglobulinemia (WM) and chronic lymphocytic leukemia (CLL). The two first entities secrete paraprotein by definition, while serum free light chains (sFLC) are increased in 50% of CLL cases. Microenvironmental factors, such as soluble Syndecan-1 (ssynd-1) and BlyS normally promote lymphoplasmacytic differentiation as well as their secretory activity, whereas others, like TGFbeta1, inhibit them. Determination of Ig is necessary in MM and WM for diagnostic purposes and for monitoring patients, while in CLL, sFLC has prognostic value. The total amount of secreted Ig does not really reflect disease burden. The heavy chain Ig can be accurately determined with the 'Heavylite' method (that measures separately HLC-IgA, -G, -M kappa or lambda), thus allowing exact quantification of the amount of pure monoclonal fraction but also the degree of suppression of polyclonal Igs, both being reflected by the corresponding ratios (HLCR).

Table 1.

		Stage*	iHL	iFLC	HLCR	FLCR	Difference HL	Difference FLC	TTT	OS

*ISS, WM-IPSS, Binet as appropriate, NS: not significant, M: median value, OS: overall survival, TTT: time to treatment

Aims: To determine any possible relationship between the amount of Igs secreted and serum sSynd1, BLyS and TGFbeta1, as well as with disease outcome.
Methods: We studied 269 patients: 105 with MM (79 IgG and 26 IgA, of whom 33%, 31%, and 36% were staged ISS 1, 2 and 3 respectively), 64 suffering from WM (44%, 28%, 28% staged WM-IPSS 1, 2, 3 respectively), and 100 with CLL (67%, 23%, 10% staged Binet 1, 2, 3 respectively). Patients were regularly followed-up from diagnosis to last visit or death (median follow-up time: 63 months). sFLC/sFLCR and HLC/HLCR were determined by nephelometry (Freelite™ and Heavylite™, the Binding Site Birmingham, UK) while sSynd1, BLyS and TGFbeta1 by ELISA, either in fresh or in frozen sera sample drawn at the time of diagnosis. Statistical analysis was performed by standard methods using the SPSS v22.0. software.
Results: The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact, with regard to patients' outcome, are shown in table.
Summary/Conclusions: sSynd1 in MM and BLyS in WM and CLL correlated with Ig production. By inhibiting both monoclonal and polyclonal Ig, TGFb1 correlated in MM with both HLC and FLC ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients' outcome.

E1305

PATIENTS WITH MULTIPLE MYELOMA (MM) IN LONG TERM COMPLETE REMISSION (LTCR) AFTER AUTOLOGOUS TRANSPLANT (APBSCT) EXPRESS A DISTINCTIVE INMUNE PROFILE WITH POTENTIAL PROGNOSIS VALUE

A. Arteche-Lopez[1,*], A. Alegre Amor[2], A. Kreutzmann[3], B. Aguado[2], M. Espiño Martinez[4], L.M. Villar[5], P. Sanz[1], A. Arriero[2], C. Muñoz-Calleja[3]
[1]Clinical Analisis, [2]Haematology, [3]Immunology, University Hospital La Princesa, [4]Haematology, [5]Immunology, University Hospital Ramon y Cajal, Madrid, Spain

Background: A small fraction of patients with MM could be considered potentially cured as long as they remain for more than six years in long term complete remission (MM-LTCR) after autologous transplant (APBSCT). The exhaustive study of the immune status of these patients could highlight interesting information.
Aims: Here we present an observational study that evaluates the numbers and phenotype of T- and B-cells subsets in the peripheral blood (PB) of MM-LTCR patients.
Methods: After approval by the ethics committee, we selected 13 patients diagnosed with MM, in sCR according to IMWG criteria for at least six years after APBSCT, and 15 healthy adults (HA) of similar ages as a comparative group. Group MM: 7 males and 6 females; median age: 61. Median follow up in sCR after APBSCT was 8 years (range 6-19). Group HA: 5 females and 10 males, median age 60 (36-78). Immunophenotype characterization was done using a comprehensive 8-color flow cytometry panel. Subpopulations of CD4+ and CD8+ T-cells from PB were quantified, including naïve, central and effector memory, regulatory T-cells, as well as subpopulations of B-cells: naïve, transitional, marginal zone-like, class-switched memory and plasmablasts. In order to confirm their specific immune signature, the analysis was repeated in the same LTCR-MM patients one year after the first analysis was done. A Kruskal-Wallis test was used to evaluate differences among the studied groups. A posteriori test was done to compare the control group with the two patient's group (patients and patients +1 year), independently of each other. A Wilcoxon matched test was used to compare a patient under group "patients" with the status of the same patient in the second group "patients +1 year". Statistical analysis was done using GraphPad Prism software.
Results: The patients had a lower percentage of total CD4$^+$T-cells (p=0.0004) together with a decrease in the naïve CD4$^+$ T-cells (CD27$^+$CCR7$^+$CD45RA$^+$; p=0.0004) and an increment of the effector memory CD4$^+$ T-cells (CD27$^-$CCR7$^-$; p=0.0028), both CD27$^-$CCR7$^-$CD45RA$^-$and CD27$^-$CCR7$^-$CD45RA$^+$ cells. Similar results were found within the CD8$^+$T-cells. No differences were observed in the Tregs defined as CD4$^+$CD25^{high}CD127$^-$. The mean percentage of total B-cells in the patients was within the normal range and no significant differences were found when compared to HA. However, naïve B-cells (CD27$^-$IgD$^+$IgM$^+$) proportion was higher in patients and a corresponding reduction of marginal zone-like B-cells (CD27$^+$IgD$^+$IgM$^+$, p=0.0047) and class-switched memory B-cells (CD27$^+$IgD$^-$IgM$^-$, p=0.0043) was observed. No differences were observed in the percentage of transitional B-cells (CD27$^-$CD10$^+$CD38$^+$) or plasmablasts (CD27^{++} CD38^{++}) in the PB of the two groups. When the analysis was repeated in the same LTCR-MM patients one year after the first analysis, no changes were detected neither when analysed as a group nor when analysed individually.
Summary/Conclusions: The MM-LTCR patients seem to express a distinctive immune "footprint" characterized by a decreased proportion of naïve T-cells and an increased percentage of effector T cells, which probably exert a competent immune surveillance. Conversely, the increase in naïve B cells may guarantee the humoral response homeostasis, including the recovery of normal plasma cells that might compete with myelomatous cells for normal bone marrow niches. The precise role of these refined immunological studies in the monitoring and therapeutic decisions in MM patients, and also in the duration of sCR, should be defined in the future.

Study partially performed with research grants from the spanish Leukemia and Lymphoma Foundation and Grant PI12/00494P from the Fondo de Investigaciones Sanitarias and FEDER funds.

E1306

IMPACT OF THE AFFORDABILITY OF NOVEL AGENTS IN PATIENTS WITH MULTIPLE MYELOMA: REAL WORLD DATA ON CURRENT CLINICAL PRACTICE IN MEXICO

L. Tarin-Arzaga[1,*], V. Martinez-Pacheco[1], A. Gomez-De Leon[1], P. Colunga

Pedraza[1], P. Santana-Hernandez[1], G. Sotomayor-Duque[1], D. Arredondo-Campos[1], C. De la Cruz-De la Cruz[1], O.G. Cantu-Rodriguez[1], D. Gomez-Almaguer[1]
[1]Hematology, Hospital Universitario Dr Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico

Background: The success of bortezomib and lenalidomide in improving outcomes as first-line therapies in multiple myeloma (MM) patients has been achieved at a very high cost. Treatment has become difficult to access for patients living in low to middle-income countries, as most receive assistance by public healthcare systems wherein novel drugs are unaffordable.
Aims: To compare the outcomes of MM patients who can afford private insurance and treatment in a private center (PrivC), with those managed in a public center (PubC), who do not have access to healthcare coverage and are treated on an out-of-pocket basis.
Methods: We analyzed records of 148 patients diagnosed with MM in two health sectors in Monterrey, Mexico, from October 2007 to July 2016; 77 (52%) from PubC, where the most common induction therapy was cyclophosphamide-thalidomide-dexamethasone, followed by thalidomide maintenance, and 71 (48%) from PrivC wherein bortezomib or lenalidomide-based induction and lenalidomide maintenance were used. We compared demographics, disease stage, response rate and survival among both groups.
Results: Median age, gender and frequency of immunoglobulin isotype did not differ significantly between the two groups. Patients treated in PubC were more likely to be diagnosed with advanced stage disease (ISS III 42% *vs* 26% p<0.05). Median follow-up was 36 months (range 3-120 months). Autologous transplantation was performed in 80% of the transplantation-eligible patients in PrivC and only in 31% of PubC. At least a very good partial response to induction therapy was achieved more often in the PrivC among transplantation-eligible (65% *vs.* 42%, p<0.05) and ineligible patients (66% *vs*. 41%, p<0.05). Overall survival was significantly higher in PrivC for transplantation-eligible (median 84 *vs*. 59 months, p<0.05) and ineligible groups (median 79 *vs* 46 months; p<0.05). After controlling for disease stage and transplantation factors, the risk of mortality was still higher in PubC (HR 1.49; 95% CI:1.0-2.2, p<0.05).
Summary/Conclusions: Stage at diagnosis, induction therapy and autologous stem cell transplantation were contributors to survival disparities between patients treated in public *vs* private health care facilities in Mexico. These findings underscore the need for more efforts to improve the affordability of novel agents and transplantation settings in public health services.

Myeloproliferative neoplasms - Biology

E1307

BASAL CALCIUM, AN IMPORTANT ELEMENT IN THE DEVELOPMENT OF CALR MUTANT MPNS

M. Morlan Mairal[1,*], P. Papadopoulos[2], M. Krstic-Demonacos [1], A. Aziz[1]
[1]Salford University, Manchester, United Kingdom, [2]Hospital Clinico San Carlos, Madrid, Spain

Background: Calreticulin (CALR) is a calcium (Ca^{2+}) buffering chaperone mutation of which has recently being associated with essential thrombocythemia and primary myelofibrosis without *JAK2* mutations. These mutations have been suggested to impair the Ca^{2+}buffering activity of Calreticulin due to a change of the negative charge in its C-terminal domain. $Ca^{2+}$is known to be important during megakaryocyte activity; however its role during megakaryopoiesis and the possible link of *CALR* mutations and abnormal megakaryocyte production due to impaired Ca^{2+} buffering activity in myeloproliferative neoplasms (MPNs) remains unclear.
Aims: Here we aim to understand how basal Ca^{2+}fluctuates during normal megakaryopoiesis and how *CALR* mutations could affect the basal Ca^{2+}levels in megakaryocytes in MPNs.
Methods: Ca^{2+} stainning was performed using Fluo-8 dye and Ca^{2+} basal levels were measured by flow cytometry. Changes in basal Ca^{2+}during megakaryopoiesis using two cellular systems, K-562 cells and mouse bone marrow cells, were measured each 24 hours. Further studies using *CALR* mutant cellular models were performed using the same methology.
Results: Our results showed a characteristic behaviour of fluctuations of basal Ca^{2+} during this megakaryopoiesis, where Ca^{2+}levels decreasein the last stage of megakaryocyte formation. These results suggest that Ca^{2+}reduction could be essential for megakaryopoiesis. In order to understand how *CALR* mutations affect basal Ca^{2+}, Marimo cells and Dami cells expressing *CALR* mutations were analysed. Here we show a decrease in basal Ca^{2+}in Marimo cells and DAMI-*CALR* type2 mutation compared to the controls. Moreover, DAMI-*CALR* type1 did not show any significant reduction, suggesting possible differences in Ca^{2+}behaviour depending in *CALR* type mutation. We are currently working in the analysis of basal Ca^{2+}fluctuations during megakaryopoiesis in the presence of *CALR* mutations and preliminary results show abnormal basal Ca^{2+}levels throughout all the process of megakaryocyte differentiation.
Summary/Conclusions: Altogether, our findings indicate that basal Ca^{2+} could be an important element during megakaryopoiesis and *CALR* mutations found in MPN could impair the normal production of megakaryocytes due to changes in cellular Ca^{2+}. However, further analysis need to be done in order to understand the role *CALR* mutations and their effect in the Ca^{2+}buffering activity of CALR in MPNs.

E1308

THE INHIBITION OF JAK/STAT SIGNALING IS COMPENSATED BY ACTIVATION OF MAPK PATHWAY IN MYELOPROLIFERATIVE NEOPLASMS

T. Subotički[1], B. Beleslin Čokić[2,*], D. Djikić[1], S. Mojsilović[3], D. Šefer[4], S. Bjelica[3], J. Santibanez[3], V. Čokić[3]
[1]Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, [2]Clinic for endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, [3]Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, [4]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: Myeloproliferative neoplasms (MPN) remain incurable regardless of advancement in the use of JAK1/2 inhibitor Ruxolitinib, which competence is unrelated to the JAK2V617F mutation.
Aims: We want to explore JAK1/2 inhibition dependency in correlation with activated JAK/STAT3 signaling and cell cycle in MPNs.
Methods: The immunoblotting has been used to analyze activation of JAK/STAT3, PI3K/AKT and MAPK signaling in JAK2V617F mutated HEL cells and granulocytes of MPN. The cell cycle and apoptosis of granulocytes are studied by flow cytometry.
Results: Concerning myeloproliferation, JAK1/2 inhibitors reduced the percentage of cells in G2M phase and increased apoptosis in JAK2V617F mutated HEL cells. Comparing to polycythemia vera (PV), the percentage of granulocytes is decreased in S and G2M phases of essential thrombocythemia (ET) and primary myelofibrosis (PMF) that demonstrated increased apoptosis. Hexabromocyclohexane increased percentage of granulocytes in GoG1 phase of JAK2V617F positive, but reduced in JAK2V617F negative PMF, the later one similar to Ruxolitinib. JAK1/2 inhibitors reduced percentage of apoptotic granulocytes in JAK2V617F positive, but increased in JAK2V617F negative PMF. JAK1/2 inhibitors could not prevent constitutive activation of JAK/STAT3 signaling in HEL cells as well as in granulocytes of JAK2V617F positive ET and PMF. Absence of JAK2V617 mutation supported dephosphorylation of JAK/STAT3 pathway by JAK1/2 inhibitors in ET, but not in PMF. JAK1/2 inhibitor

Ruxolitinib largely activates MAPK signaling in MPN, while slightly PI3K/AKT signaling in PV and JAK2V617F negative PMF. Specific JAK2 inhibitor Hexabromocyclohexane activates PI3K/AKT signaling in JAK2V617F positive ET, but reduced in JAK2V617F negative ET and PMF.
Summary/Conclusions: This observation support cross-talk between examined pathways, where inhibition of JAK/STAT3 signaling is compensated by activation of MAPK pathway irrespective of JAK2V617F mutation, while PI3K/AKT signaling demonstrates JAK2V617F dependence in MPN.

E1309

CIRCULATING PLATELET AND MEGAKARYOCYTE-DERIVED MICROPARTICLES OF JAK2V617F MUTATED PATIENTS WITH MYELOFIBROSIS ARE DISREGULATED: A NOVEL LIQUID BIOPSY TOOL OF RESPONSE TO RUXOLITINIB?

M. Barone [1], F. Ricci[2], D. Forte[1], D. Sollazzo[1], M. Romano[1], M. Spinsanti[1], E. Ottaviani[1], M. Cavo[1], N. Vianelli[1], P. Tazzari[2], F. Palandri[1], L. Catani[1,*]
[1]Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology "L. e A. Seragnoli", University of Bologna, [2]Immunohematology and Blood Bank Service, Azienda Ospedaliero-Universitaria S. Orsola-Malpighi, Bologna, Italy

Background: Microparticles (MPs) are small vesicles (0.1-1 micron) deriving from plasma membrane budding during homeostasis and cell activation. MPs express antigens and contain constituents from cell of origin and are increased in conditions that are characterized by high cell turnover or death, particularly inflammatory, autoimmune and neoplastic diseases. Myelofibrosis (MF) is a clonal neoplasia of the hematopoietic stem/progenitor cells characterized by distinctive abnormalities in megakaryocyte (MKC) development and platelet (PLT) activation. Mutations in 3 genes (*JAK2, CALR, MPL*) and chronic inflammation are the main pathogenetic drivers of MF. Ruxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammatory cytokines, reducing splenomegaly and constitutional symptoms in around 50% of patients (pts). We hypothesized that MPs, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.
Aims: This study aims to: 1) enumerate circulating MK and PLT-derived MPs of MF pts; 2) evaluate the effect of RUX on MPs production by PLT and MK; 3) investigate whether circulating MK and PLT- MPs may be a biomarker of response to RUX.
Methods: EDTA-anticoagulated peripheral blood from healthy donors (HD, n=10) and $JAK2^{V617F}$ positive MF pts (n=12) at intermediate-2/high IPSS risk was collected at baseline and 3 and 6 months after RUX therapy and immediately centrifuged. PLT (CD61+CD62P+) and MK (CD61+CD62P-)-derived MPs were analysed in PLT poor plasma samples by flow cytometry (CytoFLEX, Flow Cytometer-Beckman Coulter). The instrument was calibrated with MEGAMIX Beads (Beckman Coulter) with various diameters to cover the MPs (0.5 and 0.9µm).
Results: At 3 and 6 months, 5 out of 12 pts achieved a spleen response (R) according to 2013-IWG-MRT criteria. At baseline, the mean percentage of MK-derived MPs was significantly decreased (29±6 *vs* 72±5; p<0.0001) while that of PLT-derived MPs significantly increased (49±7 *vs* 11±1; p<0.0001) in MF pts compared to HD. However, the mean percentage of MK-derived MPs from pts not achieving a spleen response (NR) was significantly decreased compared to R (17±6 *vs* 45±5; p<0.005) and HD (17±6 *vs* 72±5; p<0.0001). By contrast, the mean percentage of PLT-derived MPs was significantly increased in NR compared to R (64±7 *vs* 37±9; p<0.05) and HD (64±7 *vs* 11±1; p<0.001). Of note, NR pts had significantly lower PLT number as compared with R pts (220±29 *vs* 422±98 p<0.05). No correlation was observed at baseline between the percentages of MK/PLT-derived MPs and platelet number, allele burden, splenomegaly and constitutional symptoms. At 3 and 6 months, RUX did not significantly modify the mean percentages of MK- and PLT-derived MPs compared to baseline values.
Summary/Conclusions: At variance with HD, the majority of circulating MPs in $JAK2^{V627F}$ mutated MF pts at intermediate-2/high IPSS risk derived from PLTs. RUX therapy did not modify the MK/PLT-derived MPs pattern, suggesting that JAK1/2 inhibition does not seem to affect the pathways of MK/PLT MPs production or clearance. Most importantly, MPs evaluation at baseline is significantly associated with subsequent spleen response. Specifically, NR pts had increased percentages of PLT-derived MPs with a concomitant reduction of PLT number. This could be related to a state of PLT hyper-activation with hyperproduction of MPs. Further studies are needed to confirm whether MPs may actually be considered a biomarker of disease activity and response to RUX.

E1310

A COMPARATIVE FUNCTIONAL AND PHENOTYPIC PLATELET ANALYSIS AMONG GENETIC GROUPS OF ESSENTIAL THROMBOCYTHEMIA PATIENTS

P. Papadopoulos[1,2,*], C. Al Assaf[2], S. Smits[2], I.M. De Cuyper[3], E. Lierman[2], T. Devos[4], A. Alvarez[5], B. Bellosillo[6], C. Besses [5], J.C. Hernández-Boluda[7], L. Gutierrez[8], P. Vandenberghe[4]
[1]Hematology, IdISCC (HCSC), Madrid, Spain, [2]Human Genetics, KU Leuven, Leuven, Belgium, [3]Blood Cell Research, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands, [4]Hematology, UZ Leuven, Leuven, Belgium, [5]Hematology, [6]Pathology, Hospital del Mar, Barcelona, [7]Hematology, Hospital Clínico Universitario-INCLIVA, Valencia, [8]Hematology, IdISCC, Madrid, Spain

Background: Essential thrombocythemia (ET) is a myeloproliferative neoplasm (MPN) characterized by a sustained elevation of platelet counts. Patients are at risk of hemorrhagic or thrombotic complications, and, eventually, of progression to acute myelogenous leukemia or marrow fibrosis. ET patients are classified on genetic subgroups based on known driver mutations (*i.e.* JAK2V617F, MPL W515K/L, CALR Type I/II). So-called triple-negative patients (TN) do not bear any of the aforementioned mutations but many other mutations that have not been hitherto shown to be causative of the disease. Cytoreductive or antiplatelet treatment is currently being used in the clinic. However, a comprehensive study of platelet properties is lacking in these patients, with updated genetic classification.
Aims: We aim to characterize platelets of the ET genetic groups and establish a phenotypic and functional profile that will help us to understand the pathophysiology of the disease and potentially add to a better patient diagnosis/prognosis.
Methods: More than 40 ET patients (from Belgian and Spanish cohorts) and healthy donors (HD) were recruited. Since treatment with acetylsalicylic acid is common, a number of HD that had taken the drug 3 consecutive days prior blood sampling were recruited. Platelets were subjected to a functional assay (Platelet aggregation) and flow cytometry analysis of surface marker expression. A novel flow cytometry based platelet aggregation assay (de Cuyper et al, Blood 2013) has been used to measure kinetics and quantitate the responses to different platelet receptors (CLEC2, GPIIB/IIIA vWF R, and collagen receptors GPVI and GPIA/IIA) upon specific agonist stimulation.
Results: Among the TN cases we identified four MPL S204F/P cases that were analyzed separately given that part of their hematological parameters (MPV, RBC counts) were not similar to the rest of the ET cases. Additionally, flow cytometry analysis also showed that MPL S204F/P platelets are larger and they have lower expression of surface markers (CD61, CD42b, CD49b, CD31) as compared to the other ET groups and HD. On the other hand, JAK2 V617F and CALR type I ET platelets exhibited normal to increased expression density of these receptors as compared to HD. Variable patterns were observed amongst the other ET genetic subgroups, with reduced responses especially upon challenge with Aggretin A or collagen, while platelets from the JAK2 ET genetic subgroup displayed hyper-reactivity to certain agonists (*i.e.* Aggretin A and Ristocetin). MPL S204F/P platelets displayed, in general,decreased aggregation responses.
Summary/Conclusions: These preliminary results suggest that MPL S204F/P platelets are intrinsically defective (hypo-reactive), in contrast to JAK2 V617F platelets (hyper-reactive), while in other genetic subgroups, potential defects are most probably synergistic and/or acquired by treatment. Data suggests that JAK2 V617F and CALR type I platelets could also undergo basal degranulation or vesiculation in the circulation. Analysis of the platelets has identified characteristics in different genetic groups of ET that should be further investigated taking into account the different treatment conditions and using larger cohorts of patients. When specific functional and phenotypic platelet patterns are established they could contribute significantly to a better diagnosis/prognosis of the disease.

E1311

ASSOCIATION ANALYSIS OF CYTOGENETIC AND GENETIC ALTERATIONS IN PRIMARY MYELOFIBROSIS

R. Norvilas[1,2,*], V. Dirse[1,3], E. Gineikiene[1], O. Mickeviciute[1], S. Pakstyte[1], M. Stoskus[1], L. Griskevicius[1,3]
[1]Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, [2]Department of Innovative Medical Technologies and Health Resort Science, State Research Institute Centre for Innovative Medicine, [3]Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background: A number of genomic abnormalities have been associated to primary myelofibrosis (PMF). Next-generation sequencing (NGS) and single-nucleotide polymmorphism array (SNP-A) methods are widely used for PMF genomic studies and certain cytogenetic and genomic associations have been determined. To better characterise the genomic landscape of PMF we performed comprehensive analysis of gene mutations and chromosomal aberrations in a population-based cohort of PMF patients.
Aims: To characterize genomic alterations in PMF using SNP-A and NGS methods.
Methods: PMF peripheral blood samples were screened by Infinium HD whole-genome genotyping assay with the HumanCytoSNP-12 BeadChips (Illumina Inc., CA). NGS analysis was performed using TruSight Myeloid 54 gene sequencing panel (Illumina). SNP-A and NGS data analyses were performed using Illumina BaseSpace Informatics suite (Illumina). *JAK2*, *CALR*, *MPL* mutations were additionally confirmed with Sanger sequencing while small indels – with DNA fragment analysis.

Results: 110 patients diagnosed with PMF according to WHO criteria between years 2013 and 2014 were included into this study. SNP-A analysis identified 77 chromosomal abnormalities in 61 patients (55,4%). These comprised the loss of heterozigosity (LOH) (59.7%), hemizygous deletions (23.4%) and copy number gains (16.9%). The most common aberrations in affected patients were: 9p LOH (55.7%), 20q deletion (11.5%), 1q duplication (4.9%), 19p deletion (4.9%), 13q deletion (3.2%), 1p LOH (3.2%) and 6q LOH (3.2%). NGS analysis detected 219 gene mutations (in a total of 27 genes) in 108 patients (98%). The most frequently mutated genes were: *JAK2* (62.9%), *CALR* (27.8%), *ASXL1* (20.3%), *TET2* (16.6%), *MPL* (7.4%), <5% *ZRSR2*, *EZH2, DNMT3A, U2AF1, ETV6, SF3B1, IDH1, IDH2*. Recurrent specific mutations were detected in 10 genes. Sixty-two patients (57.4%) had more than one somatic mutation. Six patients (5.5%) had no *JAK2*, *CALR* or *MPL* mutations and were defined as "triple-negative". Previously not described *ZRSR2* gene 12 bp insertion was indentified in four patients (3.7%). The correlation analysis showed significant associations between 9p LOH and JAK^{V617F}mutation (p<0.001); 20q deletion and *ASXL1* mutations (p=0.011); 19p deletion and *CALR* mutations (p=0.004). Notably, the affected genes are located in coresponding affected chromosome regions, indicating disruption of both alleles by different biological mechanisms. *KRAS* and *ETV6* mutations were statisticaly associated with *ASXL1* mutations (p<0.001 and p=0.005, respectively) while *JAK2* and *CALR* mutations were mutualy exclusive in all cases (p<0.001).
Summary/Conclusions: A number of associations between gene mutations and chromosomal aberations was revealed in PMF. Co-presence of 9p LOH with $JAK2^{V617F}$ and *CALR* mutations with 19p deletion indicate that further deregulation of these key signaling pathways may take place disrupting the second allele of the affected genes by different biological mechanism – LOH or deletion.

E1312

FREQUENCY OF CONCURRENT BCR-ABL1, JAK2, CALR AND MPL MUTATIONS IN A COHORT OF 5,545 CASES WITH SUSPECTED MPN BY A DEEP SEQUENCING APPROACH

S. Jeromin[1,*], M. Meggendorfer[1], A. Fasan[1], C. Haferlach[1], W. Kern[1], T. Haferlach[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm (MPN) characterized by *BCR-ABL1*, whereas in about 90% of *BCR-ABL1*-negative MPN a mutation in *CALR, JAK2* or *MPL* can be detected. These genetic alterations are thought to be nearly mutually exclusive, however, an accurate frequency is still missing.
Aims: To determine the incidence of genetic markers occurring in parallel in a large cohort of patients with suspected MPN and characterize double mutated cases.
Methods: From July 2016 till January 2017 5545 samples were sent to our laboratory with suspected MPN. The male:female ratio was 1:1, and the median age was 60 years (range: 18-98 years). Median white blood cell count was $9x10^9$/L, hemoglobin level (Hb) was 15g/dl, and platelet count was $328x10^9$/L. All of these cases were analyzed by an amplicon deep sequencing approach for mutations in *JAK2* (exon12, exon14), *CALR* (exon9) and *MPL* (exon10) with a sensitivity of 1%. 3070 patients were additionally screened for *BCR-ABL1* fusion by a multiplex PCR approach. Samples that were double mutated for *JAK2*, *CALR* and *MPL* were analyzed by amplicon deep sequencing for additional mutations in 13 myeloid genes.
Results: In total 1775/5545 (32%) of suspected MPN patients showed *JAK2, CALR* and/or *MPL* mutations. 1438 (26%) were *JAK2*, 267 (5%) *CALR,* and 89 (1%) *MPL* mutated. Of note, the analysis of a subgroup (n=3070) for *BCR-ABL1* fusion identified 123 (4%) as CML cases. The *JAK2* mutated cases presented mainly with Val617Phe (99%) and rarely with *JAK2* exon12 mutations (1%). *CALR* mutations were primarily type 1 (54%) and type 2 (30%). *MPL* mutations were located at amino acid Trp515 in 96% of cases. Double mutated cases were present in 19/1775 (1%) cases: *JAK2/MPL* (63%), *JAK2/CALR* (32%), *CALR/MPL* (5%). In nearly all *CALR* mutated cases (6/7) the *CALR* mutation was detected with the higher load, whereas in *JAK2/MPL* double mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with a load below 10% and could have been missed by other approaches. *BCR-ABL1* together with *JAK2* or *CALR* mutation was found in one patient, each (2/123, 2%). Interestingly, out of the 267 *CALR* mutated cases, 3 patients had already received treatment for CML but were suspected to have independent *BCR-ABL1*-negative MPN. For two of these patients, samples 1 and 6 years prior to diagnosis of CML were available. Both showed *CALR* mutations already at this former time-point at high loads. In 10/19 (53%) double mutated patients 13 additional mutations were detected in 8 different genes. *SRSF2* and *TET2* were the most frequently mutated ones (n=3, each). No significant difference in mutation frequency was detected to the overall frequency in MPN patients with single mutations. The *JAK2, CALR* and/or *MPL* mutated *vs* wild-type cases showed higher age (mean: 67 *vs* 56 years, p<0.001) and higher platelet counts (646 *vs* $317x10^9$/L, p<0.001). Overall, the mean age was significantly different according to the presence of mutations as follows: triple-negative (56 years), *CALR* (63 years), *JAK2* (67 years), *MPL* (71 years) and double mutated (74 years).
Summary/Conclusions: One-third of the cases can be diagnosed having MPN according to the detection of *BCR-ABL1*, *JAK2, CALR* and/or *MPL* mutation in an unselected cohort with suspected MPN. The frequency of double mutated *JAK2, CALR* and *MPL* cases is 1%. In CML cases *BCR-ABL1* fusion and *JAK2* or *CALR* mutation were detected in 2% of the patients. The impact of these parallel genetic events on the clinical course of the disease has to be evaluated in the future.

E1313

A COMPREHENSIVE ASSESSMENT OF MOLECULAR AND CYTOGENETIC MARKERS OF PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS

L. Polushkina[1,*], I. Martynkevich[1], V. Shuvaev[1], E. Motyko[1], M. Fominykh[1], I. Krivolapov[2], Z. Asaulenko[2], L. Martynenko[1], M. Ivanova[1], N. Cybacova[1], D. Shikhbabaeva[1], A. Zhernyakova[1], S. Voloshin[1], S. Bessmelcev[1], A. Chechetkin[1]
[1]Russian Research Institute of Hematology and Transfusiology, [2]North-Western State Medical University named after I. I. Mechnikov, Saint-Petersburg, Russian Federation

Background: According to resent reports the data of molecular and cytogenetic analysis (type or absence of driver mutation (DM), mutations in *ASXL1, EZH2, IDH1/2* genes, karyotype) is a promising tool for prediction of survival in primary myelofibrosis (PMF). Multiple combinations of genomic aberrations lead to clinical course and survival heterogeneity. The aforementioned factors need to be considered together to evaluate their mutual influence.
Aims: The aim of the study was to evaluate a prognostic impact of DM, mutational status of epigenetic regulation (ER) genes, karyotype and their combinations for overall survival (OS) in PMF patients.
Methods: We have examined 110 patients (pts) with PMF (34.5% males). Median (Me) age was 59 years (16-82). For all pts the detection of *JAK2*V617F was done. *JAK2(-)* samples were tested for *MPL* 515 codon mutations and exon 9 mutations of *CALR* (direct sequencing). All pts except 4 underwent the analysis of mutations in *ASXL1, EZH2, IDH1/2* genes with high resolution melting method followed by sequencing of probably mutated samples. Karyotype research was done for 48 (43.6%) pts.

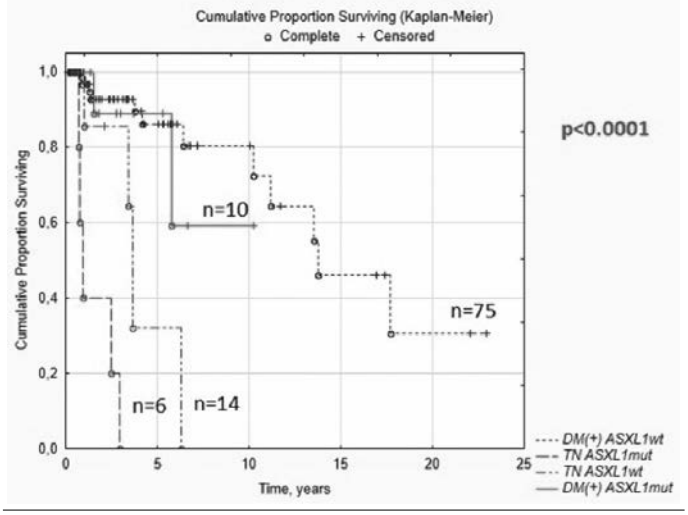

Figure 1.

Results: DM were detected in 81,8% pts: *JAK2(+)* - 50%, *CALR(+)* - 25.5%, *MPL(+)* - 6.4% cases. No DM were found in 18.2% pts considered triple-negative (*TN*). Mutations in ER genes were detected in 20.8% pts. High risk (HR) chromosomal aberrations (CA) (unfavorable CA according to DIPSS along with del(6)(q15), add(6)(p25), del(X)(q22), t(X;7)(p21;q11)) were found in 27.1% pts. Univariate analysis identified HR karyotype (hazard ratio (HR) 8.2, p<0.001), the absence of DM (HR 8.1, p<0.001) and nonsense and frameshift (hereinafter *mut*) (HR 2.9, p=0.018) but not missense mutations of *ASXL1* (p=0.378) as being prognostically detrimental for survival. *CALR* mutations had a favorable impact on survival with borderline significance (HR 0.3, p=0.052). A multivariate analysis included *TN, CALR, ASXL1* status and HR karyotype as covariates revealed an inter-independent prognostic value of HR karyotype (HR=7.4, p=0.001) and *ASXL1mut* (HR=2.8, p=0.023). In Cox regression model considering the same covariates except karyotype *TN* status (HR=2.4, p=0.050) and *ASXL1mut* (HR=3.3, p=0.012) but not *CALR* mutations (HR=0.3, p=0.075) were significant for OS. *CALR* mutations became significant (HR=0.3, p=0.075) when only *ASXL1mut* were included as covariate (HR=3.9, p=0.004). When comparing groups divided by *CALR/ASXL1* status the shortest OS was noted in *CALR(-)ASXL1mut* pts (Me 2.5 years, p=0.021). *CALR(+)ASXL1 wide type (wt)* pts seem to have better OS than *CALR(-)ASXL1wt* (median not reached (with follow up period of 10.1 years) and 13.5 years, respectively, p=0.124). Median OS estimated in pts due to presence/absence of DM and *ASXL1* status

was 0.9 years in *TNASXL1mut,* 3.6 years in *TNASXL1wt*, 13.8 years in *DM(+)ASXL1wt* and was not reached in *DM(+)ASXL1mut* (with follow up period of 10.3 years) group (p<0,0001). Differences in OS depending on the *ASXL1* status were statistically significant in the *TN* (p=0.007) but not for *DM(+)* group (p=0.788). The better OS was observed in *ASXL1wt* pts with low risk (LR) karyotype (Me 6.4 years, p=0.0005). There were no differences in OS of *ASXL1wt*-HR, *ASXL1mut*-LR and *ASXL1mut*-HR pts (1.4 *vs* 1.6 *vs* 1.2 years, p=0.493).
Summary/Conclusions: The differences in OS were more statistically relevant in groups divided by *TN/ASXL1* and karyotype/*ASXL1* status. The presence of *ASXL1mut* significantly worsens OS in the *TN* group. OS in pts with any of the findings: HR karyotype or *ASXL1mut* – was significantly shorter than in cytogenetically favorable *ASXL1wt* counterparts.

E1314

JAK2 HAPLOTYPE 46/1 (GGCC) HAS NO EFFECT ON THE PRIMARY RISK OF JAK2 V617F MUTATION, BUT IT STRONGLY POTENTIATES THE PROGRESSION OF GROWN ALLELE BURDEN IN MYELOPROLIFERATIVE NEOPLASMS

M. Stolyar[1,2,*], O. Klimova[3,4], M. Ivanov[3,4], A. Gorbenko[1], S. Titov[3,4], I. Olkhovskiy[1,5]
[1]Krasnoyarsk Branch of the Federal State-Funded Institution «National Research Center for Hematology» of the Ministry of Healthcare of the Russian Federation, [2]Siberian Federal University, Krasnoyarsk, [3]AO Vector-Best, [4]Institute of Molecular and Cellular Biology, Siberian Branch of Russian Academy of Sciences, Novosibirsk, [5]Federal Research Center "Krasnoyarsk Scientific Center of the Russian Academy of Sciences, Siberian Branch", Krasnoyarsk, Russian Federation

Background: Several research groups have determined that the JAK2 46/1 (GGCC) haplotype in multiple ethnic groups is strongly associated with a predisposition to acquiring JAK2 V617F-positive MPNs. The role of the JAK2 46/1 haplotype in the natural evolution of the mutant JAK2V617F allele burden in PV but not ET or PMF has been shown [Alvarez-Larrán A e.a. Leukemia Research 2012, 36(3):324-326]. However, the data on the impact of the haplotype on the JAK2 V617F allele burden do not always agree. Using a highly sensitive test allowed to reveal a high prevalence JAK2 V617F among persons without symptoms of hematological disorders [Krichevsky S e.a. Blood Cells, Molecules and Diseases,, doi: 10.1016/ j.bcmd.2017.01.001]. Influence of haplotype 46/1 for such cases is not known. There are two competing hypotheses of "hypermutability" and "fertile ground" explaining the causes of the higher frequency of mutations of JAK2V617F in haplotype 46/1 carriers. The "hypermutability" hypothesis refers to an increased risk of a primary mutation in carriers of haplotype 46/1. In this case, the increasing frequency of the haplotype in patients with low allelic burden (<5%) must also be observed, including those individuals without evidence of hematological disorders.
Aims: Studying the relations of haplotype 46/1 and JAK2 V617F allelic burden
Methods: The diagnosis of chronic myeloproliferative neoplasms was based on the WHO (2008) criteria. The cohort included patients with JAK2 V617F mutation: 100 patients with PV, 51 with ET, 14 with MF, 41 patients with unclassifiable MPN and 47 patients with asymptomatic V617F+ carriers. Among all patients, 17 patients were treated with hydroxyurea and 20 were treated with interferon. The control group included 100 healthy donors without JAK2 V617F mutation. SNP genotyping of two 46/1 tag SNPs, rs12340895 and rs10974944 (the G-allele, and G-allele tags the JAK2 46/1 haplotypes) was performed by a polymerase chain reaction (PCR). The JAK2V617F allele burden was evaluated by a quantitative real-time allele-specific PCR test using "in-house" kit (0.01% sensitivity). Associations between JAK2 V617F mutation and haplotypes of JAK2 were assessed using the Chi-squared test. The odds ratio (OR) and 95% confidence interval (CI) were also calculated for each comparison of JAK2 46/1 haplotype frequency and ranges of allele burden.

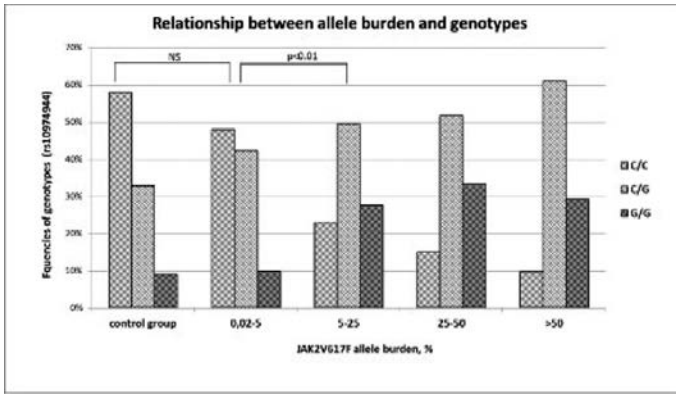

Figure 1.

Results: The JAK2 46/1 haplotype (GG and CG) was present in 170 patients (80.6%) with MPN, in 25 (52%) patients with suspected MPN, in 23 (49%) asymptomatic JAK2 V617F+ patients and in 42 (42%) cases of control group. G variant of rs10974944 was more frequent in all JAK2 V617F-positive MPNs, than in the control population (χ^2=46.5, p<0.0001). These results were similar to findings of previous studies, which have shown that the 46/1 haplotype predisposes to the acquisition of JAK2 V617F mutation. JAK2V617F allele burden was significantly higher in patients with PV than in patients with ET (p=0.001), but no differences were observed with from patients with the PMF. 46/1 haplotype was closely associated with MPN patients if the allele burden exceeds 5% (Fig. 1) regardless of the phenotype or the treatment. In this case with an increase in JAK2V617F allele burden the JAK2 46/1 haplotype frequency significantly increased. However, there was no significant difference in the JAK2 46/1 haplotype frequencies between patients with allele burden less than 5% and the control group.
Summary/Conclusions: No significant differences of the carrier haplotype 46/1 prevalence between control group and patients with minimal allelic burden (less than 5%) JAK2 2V617F have been observed. This is evidence against primary "hypermutability" hypothesis. A further increase in allelic load is more pronounced in carriers of haplotype 46/1 that supports the "fertile ground" hypothesis. We hypothesize that DNA mutation JAK2V617F repair is downgraded in 46/1 haplotype carriers.

E1315

MINIMAL RESIDUAL DISEASE MONITORING BY DIGITAL PCR FOR JAK2V617F DETECTION IN PATIENTS WITH MYELOFIBROSIS (MF) OR ACUTE MYELOID LEUKEMIA SECONDARY TO MF AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

S. Salmoiraghi[1,*], C. Belotti, M.C. Finazzi, M.C. MIcò[1], A. Algarotti[1], G. Finazzi[1], M. Mascheroni [1], A. Salvi[1], A. rambaldi[12], O. Spinelli[1]
[1]Hematology and Bone Marrow Transplant, ASST Papa Giovanni XXIII, Bergamo, [2]Oncology and Hematoncology, University of Milan, Milan, Italy

Background: Myelofibrosis (MF) is one of the *BCR-ABL1*-negative Chronic Myeloproliferative Neoplasms (MPNs), characterized by clonal expansion of abnormal hematopoietic progenitors and gradual replacement of normal bone marrow with fibrous tissue. MF patients' prognosis is widely variable and the median survival can vary from months to many years. At present, Allogeneic Stem Cell Transplantation (ASCT) is the only curative treatment option for these patients. The most frequent phenotype-driving mutation in MF is the V617F mutation in the *JAK2* gene. A high sensitive quantification of *JAK2V617F* mutation load can be useful to assess Minimal Residual Disease (MRD) in treatment directed to eradicate the malignant clone, such as ASCT. Droplet Digital PCR (ddPCR) is a quantitative approach for the detection of rare allele characterized by a high level of sensitivity and specificity.
Aims: To evaluate the efficacy of ddPCR *JAK2V617F* mutation detection assay in monitoring the MRD level at consecutive time-points in a small cohort patients who underwent an ASCT for MF or MF-derived Acute Myeloid Leukemia (s-AML).
Methods: DNA from 9 patients affected by primary, secondary MF or s-AML were serially collected during the follow-up after ASCT (50-2500 days). These samples were investigated for hematologic chimerism by PowerPlex System (Promega, USA) and were also analyzed for *JAK2V617F* mutation both by conventional allele specific PCR (ASO-PCR) and by a validated ddPCR mutation detection assay (Bio-rad, USA). Results were expressed as percentage of *JAK2V617F* mutated alleles on total evaluated alleles.
Results: The JAK2V617F ddPCR mutation assay was able to detect low mutation load (up to 0.006%), confirming to be much more sensitive than ASO-PCR (0.5-2%). In 4 patients, early after transplantation, we observed by ddPCR a low level of MRD that progressively increased during the follow-up and anticipated a decrease in donor chimerism level and a worsening of clinical situation. In 2 patients, who always showed a full donor chimerism and complete hematologic remission of the disease, very low levels of MRD (ranging from 1% to 0.006%) could be detected by ddPCR in the 2 years after ASCT. With a longer follow-up, a full molecular remission was achieved as demonstrated by ddPCR. In 2 other patients, we observed a very early achievement of full donor chimerism and JAK2V617F molecular negativity (within 90 days post HSCT), also when evaluated by ddPCR. These patients entered a complete hematologic remission of the disease which still persists (after 1 and 5 years after transplantation, respectively). Interestingly, in one patient whose post-transplant hematopoiesis proved full donor and negative for *JAK2V617F* mutation for 2 years, a weak positive signal revealed by ddPCR (0.075%) became apparent and anticipated an extra-hematologic relapse (skin and bone). A subsequent second allogeneic transplant from the same sibling donor restored clinical and molecular remission.
Summary/Conclusions: The ddPCR proved to be a sensitive and accurate method in detecting JAK2V617F mutation. Therefore, this assay can be a valid tool for the MRD monitoring in JAK2V617F MPN patients undergone an ASCT. However, the use of this highly sensitive PCR should be considered with caution in the clinical management of transplanted patients to avoid inappropriate use of donor leukocyte infusion (DLI) and tampering of immunosuppression. A large

number of patients have to be studied with ddPCR to better understand the clinical significance of low mutation load.

S100A8/9 ACTIVATION OF MAPK PATHWAY IS SUPPORTED BY ITS RECEPTORS RAGE AND TLR4 IN POLYCYTHEMIA VERA

M. Kovačić[1,*], O. Mitrović-Ajtić[1], B. Beleslin-Čokić[2], M. Diklić[3], T. Subotički[1], D. Djikić[1], S. Momčilović[1], D. Leković[45], M. Gotić[45], V. Čokić[3]
[1]Laboratory of neuroendocrinology, Institute for Medical Research, [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, [3]Laboratory of experimental hematology, Institute for Medical Research, [4]Clinic of Hematology, Clinical Center of Serbia, [5]Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: S100 proteins have been shown to regulate cell proliferation, excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is produced by cells of myeloid origin as mediator of inflammation, while AKT and MAPK pathways mediate cell proliferation.
Aims: This study analyzed activation of AKT and MAPK pathways by S100A8/9 proteins in healthy controls and MPNs: polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF), according to JAK2V617F and calreticulin (CALR) mutation status.
Methods: S100A8/9 factor is examined in granulocytes of MPN using immunoblotting, while its influence on cell cycle of granulocytes is determined by flow cytometry. Mutations of JAK2V617F and CALR exon 9 are analyzed by DNA sequencing. Besides JAK2V617F+ PV patients, we formed per three groups of patients: JAK2V617F+, JAK2V617F-/CALR+, and JAK2V617F-/CALR- for ET and PMF.
Results: S100A8/A9 proteins demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/A9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by inhibition of the receptor for advanced glycation end products (RAGE) in granulocytes of JAK2V617F+ and JAK2V617F-/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+ ET patients and JAK2V617F-/CALR- PMF patients, partially prevented by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated MAPK activation in JAK2V617F-/CALR+ ET. In contrast, S100A8/9 mediated MAPK activation has been significantly augmented by TLR4 and RAGE inhibition in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK1/2 inhibition.
Summary/Conclusions: S100A8/A9 protein levels demonstrated stable elevation in MPNs. Common inhibition of AKT pathway has been controlled by TLR4, whereas MAPK pathway activation by TLR4 and RAGE in PV, during treatment with S100A8/A9.

MUTATIONAL PROFILE STUDY OF DOUBLE-NEGATIVE ESSENTIAL THROMBOCYTHEMIA BY HIGH-DEPTH NEXT GENERATION SEQUENCING (NGS)

G. Carreno-Tarragona[1,*], I. Rapado[1], R. Ayala[1], A. Arenas[1], J. Martínez-López[1]
[1]Haematology, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Essential thrombocythemia is one of the three classical philadelphia negative myeloproliferative neoplasms. It is frequently difficult to diagnose and some molecular markers are used as diagnostic criteria according to WHO classification. Despite this, a significant proportion of patients do not present a clonality marker.
Aims: To identify the mutational profile of ET negative for V617F and CALR mutations and to correlate it with clinical data.
Methods: A cohort of 22 ET negative for mutations in JAK2 (qPCR) and CALR (GENESCAN) was selected. Median age at diagnosis was 46 years (range: 14-88), male:female ratio 9:13; 2 patients had a record of thrombotic event prior to diagnosis, 4 patients had symptoms at the time of among diagnosis, 3 patients suffered a thrombotic event after diagnosis, 1 patient suffered transformation to AML. Median Hb, WBC and platelets at diagnosis were respectively 14.75g/dl 8,85 x10^9/L and 720x10^9/L. We performed targeted gene sequencing by NGS (Ion Torrent Proton System–Life Technologies) using a panel of 33 genes implicated in leukemia prognosis. X2 and t-student tests were used to find association between mutations and clinical data.
Results: On average, 97.94% of the target sequence showed a mean depth coverage around 2500. We discovered 17 non-synonymous mutations which 16 were somatic single nucleotide variants (SNVs) and 1 a nucleotide deletion in coding regions. No mutations were detected in 9 samples (40.9%), 10 samples presented 1 mutation (45.5%), and the other 3 samples present 2 or more mutations (13.6%). TET2 was the most frequently mutated gene (18.2% of patients, mean allele frequency of 24,45%), followed by JAK2 (13.6% V617F at a low mean allele frequency (5.8%), MPL (9.1%, one W515L, one with two mutations W515R and S505C, mean allele frequency of 21,95%), SF3B1 (4.5%), DNMT3A (4.5%), KIT (4.5%), VHL (4.5%), CBL (4.5%) and KMT2A (4.5%). The samples with more than one mutation: one presented a CBL and two TET2 mutations, one two mutations in MPL and the other one mutation in TET2 and other in JAK2. No correlation was found between mutational profile and clinical data.
Summary/Conclusions: In ET, around 60% of patients present the JAK2V617F mutation, 15-30% show CALR mutations and around 5% present MPL mutations. In spite of this, there is still a significant percentage of ET patients without a molecular marker. Our study shows that the use of a NGS panel allows identifying markers of clonality as for example TET2. NGS also makes affordable to interrogate whole genes classically associated to ET, to detect mutations that were not found by traditional approaches. Finally, we can conclude, as previously described, that ET is an entity with a low mutational burden in comparison with other MPNs as primary myelofibrosis.

E1318

TCR GAMMA CLONALITY ASSESSED BY NGS DOES NOT HELP TO DISTINGUISH EGPA FROM HES

S. Galimberti[1,*], E. Ciabatti[2], F. Guerrini[1], M. R. Metelli[3], I. Petrini[4], G. Tarrini[3], M. Latorre[5], E. Elefante[6], F. Ferro[6], R. Grossi[7], N. PIsanti[7], S. Grassi[8,9], M. Petrini[9], M. Mosca[6], C. Baldini[10]
[1]Clinical and Experimental Medicine, University of Pisa, Hematology, [2]Clinical and Experimental Medicine, University of Pisa, Hematology, [3]Hematology Molecular Laboratory, AOUP, [4]Department of Translational Research and New Technology in Medicine, General Pathology, [5]Cardio-Thoracic and Vascular Department, [6]Department of Clinical and Experimental Medicine, University of Pisa, Rheumatology, [7]Department of Informatics, University of Pisa, Pisa, [8]GENOMEC doctorate school, Siena, [9]Department of Clinical and Experimental Medicine, University of Pisa, Hematology, [10]Department of clinical and experimental medicine, rheumatology, Pisa, Italy

Background: Hypereosinophilia-associated syndromes are a heterogeneous group of diseases characterized by sustained and elevated blood eosinophilia with evidence of eosinophil-induced organ damage. Classically, Eosinophilic Granulomatosis with Polyangiitis (EGPA) and Hypereosinophilic Syndrome (HES) present several overlapping clinical and laboratory features, making it challenging to correctly insert patients in restricted and well-defined categories with specific and more effective therapeutic approaches in daily practice. Therefore, great efforts are ongoing searching for novel biomarkers able to differentiate these two disorders.
Aims: To detect T cell receptor gamma (TCRG) clonal rearrangements in EGPA and HES, comparing the frequency of distribution of the V and J region segments in 21 patients afferent to the hematology, rheumatology or pulmonology divisions.
Methods: Consecutive patients with a diagnosis of EGPA and HES were enrolled into the study. Inclusion criteria were: documentation of a persistent peripheral eosinophilic count of ≥1.5 x10^9/L and signs or symptoms of organ involvement. Clinical and laboratory data of the patients were collected. Sequence-based determination of the frequency distribution of TCRG Gene Rearrangements was performed using next-generation sequencing with the Illumina MiSeq (LymphoTrack TRG assay, Invivoscribe).
Results: We included 21 patients (9 with EGPA and 12 with HES). Four EGPA patients were MPO-ANCA positive. We detected TCRG clonal rearrangements in 44% patients with EGPA and in 42% patients with HES. No association was observed between TCRG clonal rearrangements and ANCA status in EGPA patients. The following recurrent TCRG gene rearrangements were observed: Vg10JgP1 (5 cases) and Vg4Jg1/2 (4 cases) were observed in both EGPA and HES, whereas Vg9Jg1/2 (2 cases) and Vg10Jg1/2 (2 cases) were observed only in patients with HES. The presence of TCRG rearrangement was not different according to the symptoms (asthma, vasculitis, skin, heart, gut, lung involvement, splenomegaly). IL2, IL5, IL4, eosinophil cationic protein (ECP), absolute eosinophils were measured: IL5 and ECP were higher in the polyclonal than in the clonal cases (9±2.5 *vs* 1.7±0.9; p=0.021 and 121.8±61.5 *vs* 39.5±1.5; p=0.07). On the contrary, no difference was observed in the absolute eosinophil count. Finally, the presence/absence of TCRG clonality did not significantly impact on the response to treatment (immunosuppressive or interferon) and on the progression-free survival length.
Summary/Conclusions: Conclusions: Even if preliminary, this study reveals a similar T cell receptor gamma repertoire in EGPA and HES, with recurrent rearrangements, thus suggesting a possible antigen-driven inflammatory response underlying hypereosinophilia in both EGPA and HES. Interestingly, this study confirms our previous results showing the TCR delta rearrangement (assessed by qualitative PCR) in 40% of the EGPA patients.

PROINFLAMMATORY CYTOKINE IL-6 STIMULATION OF ANGIOGENIC FACTORS AND DNA REPLICATION IS BLOCKED BY JAK-STAT PATHWAY INHIBITION IN MYELOPROLIFERATIVE NEOPLASMS

T. Subotički[1,*], B. Beleslin Čokić[2], D. Leković[34], S. Mojsilović[5], O. Mitrović Ajtić[1], M. Kovačić[1], M. Diklić[5], M. Gotić[34], V. Čokić[5]

[1]Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, [2]Clinic for endocrinology, Diabetes and Metabolic Diseases, [3]Clinic of Hematology, Clinical Center of Serbia, [4]Medical Faculty, University of Belgrade, [5]Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: We already demonstrated augmented proinflammatory IL-6 and angiogenic vascular endothelial growth factor (VEGF), hypoxia inducible factor-1α (HIF-1α) and endothelial nitric oxide synthase (eNOS) levels in myeloproliferative neoplasms (MPN).
Aims: To observe IL-6 activated signaling pathways during stimulation of angiogenic factors and their JAK-STAT dependence in MPN.
Methods: We analyzed phosphorylation of JAK/STAT3, PI3K/AKT and MAPK signaling by immunoblotting in HEL 92.1.7 cells (with JAK2V617F mutation) and granulocytes of MPN. The granulocyte cycle phases have been studied by flow cytometry.
Results: We demonstrated IL-6 stimulated angiogenic factors in HEL cells and HEL-derived macrophages, blocked by JAK-STAT inhibition for eNOS and HIF-1α. IL-6 stimulated JAK-STAT3 and angiogenesis related PI3-AKT signaling pathways in HEL cells, the later one prevented by JAK1/2 inhibition. Opposite to primary myelofibrosis (PMF), IL-6 activation of JAK-STAT3 and PI3-AKT pathways has been prevented and enhanced by JAK1/2 inhibition, respectively in granulocytes of polycythemia vera (PV). Moreover, IL-6 inhibition of JAK-STAT3 and PI3-AKT pathways in essential thrombocythemia (ET) has been prevented by JAK2 inhibitor in JAK2V617F positive ET granulocytes. JAK1/2 inhibitor Ruxolitinib upregulated IL-6 activation of MAPK pathway in MPN, in contrast to specific JAK2 inhibitor Hexabromocyclohexane. IL-6 mediated reduction in the percentage of HEL cells in G2M phase was inversed by Ruxolitinib that potentiated apoptosis and reduced the cell percentage in G0G1 phase both in HEL cells and granulocytes of PMF. It has been detected the cell cycle arrest of MPN granulocytes in S phase (DNA replication) after treatment with IL6, completely diminished by JAK1/2 inhibition.
Summary/Conclusions: Therefore, we concomitantly revealed that inflammation stimulated angiogenic factors and signaling pathways involved in cell proliferation, apoptosis and angiogenesis are regulated by JAK-STAT inhibition.

Myeloproliferative neoplasms - Clinical

PERCEPTION OF SYMPTOM BURDEN AND TREATMENT GOALS BETWEEN PHYSICIANS AND PATIENTS WITH MPNS: AN ANALYSIS FROM THE INTERNATIONAL MPN LANDMARK SURVEY

L. Foltz[1,*], S. Koschmieder[2], C.N. Harrison[3], P. Guglielmelli[4], T. Flindt[5], M. Koehler[6], J. Mathias[7], N. Komatsu[8], R.N. Boothroyd[9], A. Spierer[9], J. Perez Ronco[10], G. Taylor-Stokes[11], J. Waller[11], R.A. Mesa[12]
[1]St. Paul's Hospital, University of British Columbia, Vancouver, British Columbia, Canada, [2]Department of Hematology, Oncology, Hemostaseology, and Stem Cell Transplantation, Faculty of Medicine, RWTH Aachen University, Aachen, Germany, [3]Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom, [4]CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, [5]Patient advocate, Prato, Italy, [6]Department of Hematology and Oncology, Faculty of Medicine, Otto-von-Guericke University Magdeburg, Magdeburg, Germany, [7]Patient Chair, MPN Voice, London, United Kingdom, [8]Department of Hematology, Juntendo University Faculty of Medicine, Tokyo, Japan, [9]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States, [10]Novartis Pharma AG, Basel, Switzerland, [11]Adelphi Real World, Bollington, United Kingdom, [12]Mayo Clinic, Scottsdale, AZ, United States

Background: The global MPN LANDMARK survey evaluated the patient (pt) and physician-reported impact of myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), among pts from 6 countries. We present an analysis comparing physician and pt perceptions of the impact of these MPNs.
Aims: To investigate differences between pt and physician perceptions of symptom burden, treatment goals, and disease management
Methods: This was a cross-sectional survey of pts with MPNs and physicians treating pts with MPNs. Respondents completed an online survey measuring their perception of the impact of MPNs on symptom burden, disease management, and treatment goals. Pts and physicians were recruited independently.

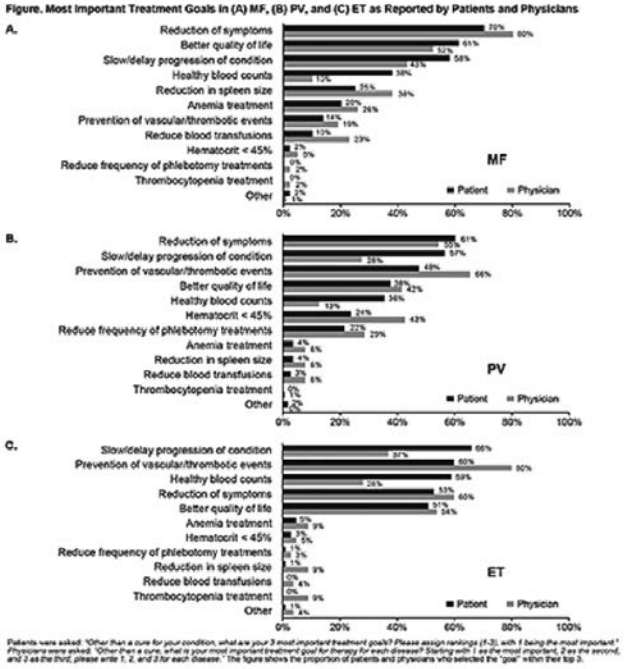

Figure 1.

Results: Pts (n=699) from Australia (n=10), Canada (n=64), Germany (n=149), Italy (n=106), Japan (n=84), and the UK (n=286) completed the survey (MF, n=223; PV, n=174; ET, n=302). Most pts had been diagnosed within ≤2 years of experiencing symptoms (73%); 56% were women. Physicians (n=219) were from the same countries; most were hematologists (54%) or hemato-oncologists (27%). Overall, 54% of pts reported having a prognostic score; however, 71% of physicians reported using a prognostic risk classification. Physicians assessed symptoms by proactively asking pts how they were feeling (43%) or asking about specific symptoms (37%); 11% waited for pts to mention symptoms. Importantly, only 26% of physicians used a validated symptom assessment form; 44% used their own rating method. Pts and physicians both agreed that pts with MPNs have a high symptom burden and that MF had a higher degree of burden on daily living. Interestingly, a higher proportion of physicians

than pts felt that MPN symptoms have an impact on pt quality of life (92% *vs* 76%) and that pts had a substantial emotional burden associated with their disease. For instance, 34%, 29%, and 26% of pts with MF, PV, or ET reported feeling anxious or worried compared with 70%, 46%, and 36% of physicians reporting that their pts experience substantial anxiety or worry. Some pts did not recognize that their symptoms could be MPN related; for example, ≈ one-fifth of pts did not think that their night sweats could result from their MPN (16% MF, 21% PV, 25% ET). Consistent with this, 60% of physicians indicated that pts could identify only few or some of their symptoms as MPN related. Pts and physicians were both concerned about reducing symptoms (pts: 70% MF; 61% PV; 53% ET; physicians: 80% MF, 55% PV, 60% ET); however, pts were also concerned about delaying MPN progression (58% MF, 57% PV, 66% ET; physicians: 43% MF, 28% PV, 37% ET; **Figure 1**). Compared with pts, physicians indicated a greater focus on prevention of vascular/thrombotic events in PV (66% *vs* 48%) and ET (80% *vs* 60%). Overall, only 27% of physicians felt they completely agreed with their pts on treatment goals; 66% felt they "somewhat" agreed. However, most pts (87%) were satisfied with their physician's disease management/communication.

Summary/Conclusions: This study revealed a potential disconnect between physician and pt perceptions relating to communication and disease management, and an apparent lack of standardization in symptom assessment. Of note, some pts did not recognize that their symptoms could be MPN related and had different treatment goals than their physicians, indicating a need for improved pt education and pt-physician communication and a treatment plan that includes standardized monitoring of symptoms and agreement on treatment goals.

E1321

BASELINE QUALITY OF LIFE INDEPENDENTLY PREDICTS OVERALL SURVIVAL IN THE MYELOFIBROSIS: KEY INSIGHTS FROM THE COMFORT-I STUDY

R. Scherber[1,2,*], H. Kosiorek[3], H. Geyer[4], S. Verstovsek[5], J. Sloan[6], B. Langlais[3], L. Padrnos[1], J. Palmer[1], A. Fleischman[7], A. Dueck[3], R. Mesa[1]
[1]Hematology and Oncology, Mayo Clinic, Scottsdale, [2]Hematology and Oncology, Oregon Health and Science University, Portland, [3]Biostatistics, [4]Internal Medicine, Mayo Clinic, Scottsdale, [5]Hematology and Oncology, MD Anderson, Houston, [6]Biostatistics, Mayo Clinic, Rochester, [7]Hematology and Oncology, University of California Irvine, Irvine, United States

Background: Quality of life (QOL) is a critical aspect of cancer treatment and survival. A strong association exists between QOL and overall survival (OS) for numerous malignancies including breast, gastro-esophageal, colorectal, lung, prostate, ovarian, and head and neck cancer (Sloan 2012, Montazeri 2009, Nilsson 2017). Healthcare organizations have used symptom burden as a primary therapeutic endpoint when assessing the benefit of JAK inhibitors in myelofibrosis (MF) in clinical trials, although QOL was also considered. To date, little is known about the association of these items in regards to overall survival in MF.

Aims: To evaluate the prognostic relevance of QOL and symptom burden among patients with MF from the COMFORT-I study.

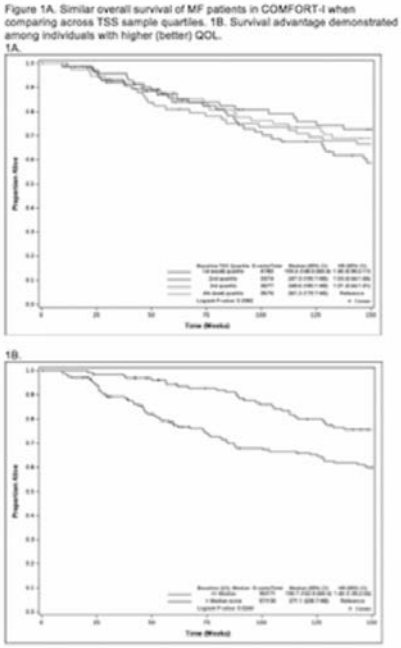

Figure 1.

Methods: Data from the COMFORT-I trial of ruxolitinib (Verstovsek 2012) *versus* placebo was obtained from Incyte© for independent analysis. Association of total symptom burden (TSS; divided by the sample quartiles) and QOL (divided by the sample median) at baseline with OS among MF patients was estimated using the Kaplan-Meier method and tested using log rank tests and Cox regression. Symptom burden and QOL were assessed using the 5-symptom MF-SAFv2.0 (Mesa 2009) and EORTC QLQ-C30 Global Health/QOL scale (Aaronson 1993), respectively. The PROMIS instrument was used to assess fatigue (Cella 2007).

Results: A total of 309 patients were available for analysis including 155 ruxolitinib-treated and 154 placebo-treated MF patients. Baseline demographics, disease-related variables, and calculated overall survival were similar to previous published results (Verstovsek 2015). *Symptom Burden*: When comparing OS by TSS quartiles at baseline, no significant associations in OS were observed (Figure 1A). Individual symptoms of bone or muscle pain, feeling full, pain under ribs on left side, abdominal discomfort, itchiness, or night sweats also did not demonstrate significant associations when comparing OS by quartile symptom score. Baseline fatigue score demonstrated no difference in OS when stratified by median or quartiles. *Global Health Status/QOL*: Intention to treat analysis demonstrated significant survival advantage for patients with higher QOL at baseline (HR 1.47, p=0.02, Figure 1B). When censoring placebo patients at crossover, this hazard ratio improved to a HR 1.79 (p=0.008). *Cox Proportional Hazards Modeling*: Cox regression for survival analysis reached significance for items of age (p<0.001), sex (p<0.009), and QOL (p=0.009) when taking into consideration TSS, IPSS prognostic risk score, age, sex, COMFORT treatment arm, and QOL. When censoring for placebo patients at crossover, this analysis demonstrated that the same items remained significant (age [p=0.001], sex [p<0.001], and QOL [p=0.002]).

Summary/Conclusions: For the patients prospectively evaluated in the COMFORT-I trial, pre-treatment QOL is strongly prognostic for overall survival and remains highly prognostic even when adjusting for symptom burden, disease risk, age, sex, and treatment. Prior literature has confirmed the importance of QOL in prognosticating survival in other cancer types. However, this is the first study that has identified the key correlation among individuals with MF. Neither individual nor combined symptom scores at baseline appeared prognostic for overall survival, emphasizing the importance of QOL assessment in addition to symptom assessment. Weight loss (a prognostic factor for DIPSS scoring) was not included in this symptom burden assessment and may represent an independent factor associated with increased survival.

E1322

CHARACTERIZATION OF DISEASE AND OUTCOMES OF PATIENTS WITH MYELOFIBROSIS: A POPULATION BASED STUDY

J. He[1,*], M. Mehra[1], J. Bussolari[2], A. Rizo[2], S. Mundle[1]
[1]Janssen Global Services LLC, [2]Janssen Research & Development, LLC, Raritan, United States

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm with profound negative effects on health related quality of life and survival. It is characterized by clonal myeloproliferation, ineffective erythropoiesis, bone marrow stromal changes, hepatosplenic extramedullary hematopoiesis, and aberrant cytokine expression. Although progress has been made in the understanding of the pathogenesis and management of MF, there are still unresolved issues regarding prognosis and causes of death.

Aims: This population-based study characterizes disease and outcomes in patients (pts) with MF by using the U.S. Surveillance, Epidemiology, and End Results (SEER) database.

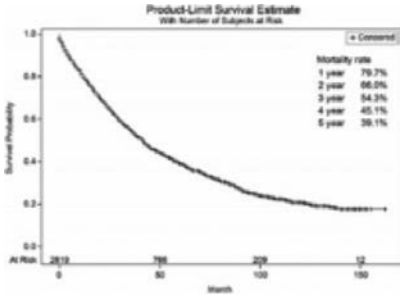

Figure 1.

Methods: We identified a total of 3,367 pts with primary myeloid fibrosis (PMF, ICD-O-3 morphology code as 9961/3 and primary site code as C420, C421 or C424) diagnosed between January 2000 to December 2013. Pts with missing survival status (n=753), pts lost to follow up (n=4), and pts with missing age record (n=1) were excluded. Kaplan-Meier analysis was performed to determine overall survival (OS) and cancer specific mortality. The effects of specific covariates on OS were analyzed using a Cox proportional hazards model.

Results: The final study cohort comprised of 2,619 PMF pts. Median follow up period was 28 months (interquartile range (IQR),11-56). Median age at diagnosis was 68 years (interquartile range 59-77 years) with 60.6% (n =1,586) ≥ 65 years old. More than half of the pts were male (58.5%; n=1,531); 82.2% (n=2,153) were white, and 16.4% (n=430) were diagnosed between 2012 and 2013. The geographic distribution was as follows: East 14.8%, South 18.4%, West 54.2% and Midwest 12.6%. Median OS was 42 months (Figure 1). The hazard ratio of all-cause mortality for age was 1.05 (95% Confidence interval (CI) 1.04-1.05), for female *vs* male was 0.72 (CI 0.64-0.80), for nonwhite *vs* white 1.01 (CI 0.87-1.16), for unmarried *vs* married was 1.04 (CI 0.94-1.16), for patients diagnosed 2012-2013 *vs* 2000-2011 was 0.95 (CI 0.75-1.20). Compared to West, the hazard ratio of OS for East, South and Midwest was 1.05 (CI 0.90-1.22), 1.28(CI 1.12-1.47), 1.03(CI 0.88-1.19) respectively.
Summary/Conclusions: This population based study showed that the overall survival of pts with PMF was short. Older and male pts were associated with higher mortality risk. There were significant differences across geographic regions of the United States. Although there is a trend of improvement in the period of 2012 to 2013, the result is not statistically significant, partially due to short follow up. These findings underscore the continuing need for effective therapies for pts with MF.

E1323

SERUM ALBUMIN IS A STRONG PREDICTOR OF SURVIVAL IN MYELOFIBROSIS, INDEPENDENT OF IPSS, DIPSS, AND DIPSS+ SCORES

A.T. Kuykendall[1,*], C. Talati[1], D.A. Sallman[2], K.L. Sweet[2], E. Padron[2], J.E. Lancet[2], A.F. List[2], K.S. Zuckerman[2], R.S. Komrokji[2]
[1]University of South Florida/Moffitt Cancer Center, [2]Moffitt Cancer Center, Tampa, United States

Background: Albumin is the main protein in human plasma. Serum albumin (SA) is used as a surrogate marker of nutritional status and inflammation. The prognostic role of SA has been studied in many diseases, including hematologic malignancies. In myelofibrosis (MF), ruxolitinib has been shown to improve SA levels in addition to other metabolic parameters. SA holds particular significance in MF given its ability to capture both nutritional status and inflammation level in a disease hallmarked by hyperactive inflammatory pathways and constitutional symptoms.
Aims: We aim to closely evaluate the significance of SA in MF patients as it pertains to clinical presentation, laboratory correlations, disease genomics, comorbidities and outcomes.
Methods: We retrospectively reviewed an institutional database of 376 MF patients who presented to Moffitt Cancer Center between 1/1/1998 and 12/31/2012 and had available SA levels within 30 days of presentation. Laboratory values and prognostic scores were determined at time of first presentation. Overall survival (OS) was measured from time of first presentation until date of death or censored at time of last follow-up. Progression free survival (PFS) was defined as time from first presentation to development of acute myeloid leukemia (AML).

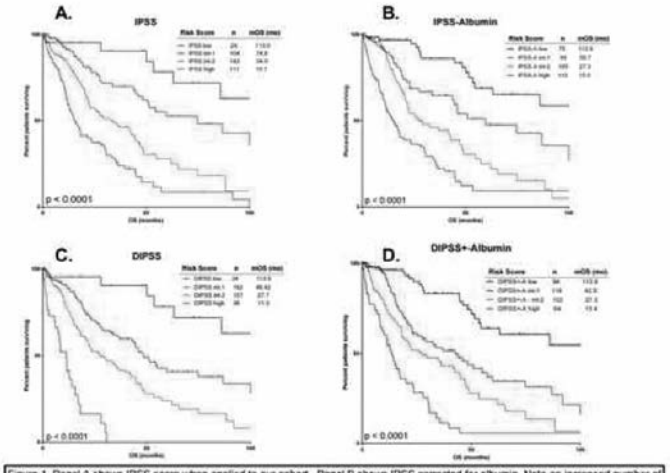

Figure 1. Panel A shows IPSS score when applied to our cohort.. Panel B shows IPSS corrected for albumin. Note an increased number of low-risk patients that are captured with equivalent median OS. Panel C shows DIPSS as applied to our cohort. Panel D shows DIPSS corrected albumin. Note, more low and high-risk patients are captured with comparable median OS.

Figure 1.

Results: Our cohort of MF patients had median age of 67 and 69 at diagnosis and presentation, respectively. Most patients had primary MF (73%) with 11% and 16% having post-PV MF and post-ET MF, respectively. First, we looked at the correlation between SA and other clinical factors. SA was positively correlated with hemoglobin (p<0.01) and platelet count (p<0.01), and negatively correlated with age (p<0.01), peripheral blast percentage (p=0.03), ferritin (p<0.01), prognostic scoring models (p<0.01 for IPSS, DIPPS and DIPSS+) and pack-year smoking history (p<0.01). SA did not correlate with spleen size or any specific somatic mutation, but negatively correlated with somatic mutation burden (p=0.03). On univariate regression, SA was associated with inferior PFS (HR: 0.31 [0.13-0.72]; p<0.01) and OS (HR: 0.25 [0.17-0.36]; p<0.01). Four cohorts were created based on SA: cohort I=SA 2.5-3.5 g/dL (n=31); cohort II=SA 3.6-4.0 g/dL (n=99); cohort III=SA 4.1-4.5 g/dL (n=182); and cohort IV=SA>4.5 g/dL (n=64). OS increased with increasing SA; with median OS (in months) of 9.34, 25.3, 48.4, and undefined in cohorts I-IV, respectively. On focused comparison, each cohort was significantly different than all others. On multivariate analysis, the influence of SA on OS remained significant after controlling for prognostic scores (IPSS, DIPSS, DIPSS+) and comorbidities. For PFS, SA remained significant when controlling for IPSS and DIPSS, but lost significance (p=0.08) when controlling for DIPSS+. Multivariate analysis was performed on a cohort of patients with available molecular data (n=138). SA significantly influenced OS after controlling for prognostic systems, comorbidities and mutations of *SRSF2* and *ASXL1*. Lastly, given its independent prognostic value, we incorporated SA into pre-existing prognostic models. For IPSS, DIPSS, and DIPSS+, patients were assigned 0, 1, 2, and 3 points for low (LR), intermediate-1 (int-1), intermediate-2 (int-2), and high risk (HR), respectively. Patients were then assigned -1, 0 and 1 point for SA >4.3, 3.8-4.3, and <3.8 g/dl, respectively. Risk groups were defined as LR (-1-0 points), int-1 (1 point), int-2 (2 points), and HR (3-4 points). Survival curves and histograms displayed better capture of LR and HR prognostic groups with median OS similar to standard prognostic modeling (see figure).
Summary/Conclusions: SA level is independently prognostic in MF and correlates with variables known to hold prognostic value. Its representation of nutritional status, inflammation, and comorbidities imbues it with special status in predicting outcome. Its incorporation into known prognostic scoring systems provides an improved ability to accurately capture low and high-risk subgroups.

E1324

CLINICAL UTILITY OF NEXT-GENERATION SEQUENCING IN THE MANAGEMENT OF MYELOPROLIFERATIVE NEOPLASMS

W. Alduaij[1,*], C. McNamara[1], A. Schuh[2], A. Arruda[1], M. Sukhai[3,4], M. Thomas[3], J.Y. Spiegel[1], J.A. Kennedy[2,5], T. Stockley[3], H. Tsui[6], R. Devlin[1], N. Siddiq[1], H. Sibai[1], D. Maze[1], A. Schimmer[2], K. Yee[2], S. Chan[2], S. Kamel-Reid[7], V. Gupta[1]
[1]MPN program, Princess Margaret Cancer Centre, [2]Hematology- Princess Margaret Cancer Centre, [3]Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, [4]Applied Molecular Oncology, Ontario Cancer Institute, University Health Network, University of Toronto, Toronto, Canada, [5]Division of Hematology, Department of Medicine, Brigham and Women's Hospital, Boston, MA, United States, [6]Department of Hematopathology, Toronto General Hospital, [7]Molecular Diagnostics, Department of Pathobiology and Laboratory Medicine, University Health Network, University of Toronto, Toronto, Canada

Background: Although Next Generation Sequencing (NGS) has helped characterize the complex genomic landscape of myeloid malignancies, its clinical utility remains not well defined. Funding for NGS testing by healthcare systems or third party payers is variable due to the lack of data on its utility in a routine care setting. At our centre, targeted sequencing (TAR-seq) is offered to all new patients referred for myeloid malignancies as part of the Advanced Genomics in Leukemia (AGILE) project.
Aims: In this study, we evaluate the impact of TAR-seq on the management of patients with a diagnosis of MPN or post-MPN acute myeloid leukemia (MPN/AML).
Methods: All consenting patients referred to the MPN program at the Princess Margaret Cancer Centre between February 2015 and December 2016 with a suspected or confirmed diagnosis of MPN were evaluated (*n*=188). TAR-seq was performed on DNA extracted from peripheral blood (*n*=159, 85%) or bone marrow (*n*=29, 15%) using the TruSight Myeloid Sequencing Panel (Illumina), a targeted NGS panel of 54 genes (39 hotspot region; 15 complete coding region coverage) implicated in myeloid malignancies. Reporting was restricted to high quality exonic nonsynonymous, intronic splice site, frameshift, nonsense and known pathogenic synonymous variants. Variants with global mean allele frequency >1% were identified using multiple population databases (1000 genomes, ESP, ExAC) and excluded. Each patient's TAR-seq results were reviewed alongside their clinical information systematically by at least two hematologists with expertise in MPN, and disagreements were resolved by consensus.
Results: 179 patients fulfilled the 2008 WHO diagnostic criteria for MPN: 107 were diagnosed with myelofibrosis (MF), 26 with polycythemia vera (PV), 21 with essential thrombocythemia (ET), 13 with other MPNs including MPN-unclassifiable and 12 with MPN/AML. In 6 patients with 'triple negative' MPN, who lacked mutations in the driver genes *JAK2*, *CALR* and *MPL*, TAR-Seq confirmed clonal hematopoiesis through identifying other mutations. In 61 transplant-eligible patients with MF, 32 (52%) were considered to carry a *high molecular risk* (HMR) profile based on harboring at least one mutation in *ASXL1*, *EZH2*, *IDH1/2*, *SRSF2* or *TP53*; or a total of three or more mutations. Of these, 11 patients (34%) were considered for early transplant, three with Intermediate-1 and eight with Intermediate-2 risk, who were responding well to JAK 1/2

inhibitor (JAKi) therapy. All high-risk, transplant-eligible MF patients were considered for transplant irrespective of their HMR status. Nine patients with low/intermediate-1 risk MF bearing HMR mutations were considered for a clinical trial of early JAKi therapy, and one patient was successfully enrolled. Seven patients were identified with *IDH1/2* mutations (five with MF and two with MPN/AML), and therefore can be potential candidates for enrolment into clinical trials evaluating novel IDH 1/2 inhibitors. In PV and ET, TAR-seq identified HMR profiles in 6/26 (23%) and 5/21 (24%) patients, respectively. These patients are monitored closely, but no therapeutic decisions were taken based on their HMR profile. In MPN/AML, *TP53* mutations were detected in 4/12 (33%) patients. However, these patients progressed rapidly before their TAR-seq results became available to inform clinical management.

Summary/Conclusions: We have determined that TAR-seq improves the characterization of triple negative MPN patients, refines risk stratification and decisions related to the timing of transplant in MF, and can potentially identify candidates for future targeted therapies. Therefore, we suggest that NGS should be part of the standard of care in MF, and in the investigation of triple negative MPN. Based on these findings and in conjunction with ongoing studies in the MPN program, an algorithm integrating NGS in the management of MF has been developed, and will be evaluated prospectively.

E1325

IMPACT OF COMORBIDITIES AND BODY MASS INDEX ON SURVIVAL IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

Ematologia, Ospedale Nuovo Regina Margherita, Roma, Italy

Background: Charlson Comorbidity Index (CCI) and body mass index (BMI) are significantly associated with outcome in patients (pts) who receive continue treatment with tyrosine kinase inhibitors. Ruxolitinib (RUX) is the first JAK1/2 inhibitor that may induce spleen/symptom responses and improve quality of life in pts with myelofibrosis (MF). No data are yet available on the impact of comorbidities and BMI on pts treated with RUX.

Aims: To evaluate the impact of CCI and BMI on overall survival (OS) in a cohort of RUX-treated MF pts.

Methods: A multicenter observational study on WHO-defined MF treated with RUX according to standard clinical practice was conducted in 20 Italian Hematology Centers. Response to RUX was evaluated according to 2013 IWG-MRT criteria. OS was calculated from the date of RUX start to the time of death or last follow-up. Baseline parameters evaluated for correlation with OS were: blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, mutation status, Total Symptom Score (TSS), CCI, and BMI.

Results: Between June 2011 and Apr 2016, 343 pts with PMF (51.9%), or post-ET (20.1%) / post-PV (28.0%) were treated with RUX in participating Centers. At RUX start, median age was 67.6 years (range 36.5-89.0) with a male prevalence (57.1%); International Prognostic Score System (IPSS) was intermediate (intm)-1 (16.0%), intm-2 (47.5%), high (36.4%). Transfusion dependence and spleen enlargement were present in 23.9% and 97.4% of pts, respectively (62.4% with spleen ≥10 cm). TSS was <20 in 131 pts (38.2%); 62 (18.1%) pts had a BMI<21 (corresponding to lower quartile). CCI was zero in 105 pts (30.6%), one in 74 pts (21.6%), two in 58 pts (16.9%) and ≥ 3 in 106 pts (30.9%). Median follow-up from MF diagnosis was 3.6 yr (range 0.4-25.6) and median RUX exposure was 21.2 months (3-56.2). In multivariable Cox regression analysis, factors negatively correlating with OS from RUX start were: transfusion dependence (HR: 2.65; p<0.001), CCI ≥3 (HR: 1.67; p=0.031), BMI<21 (HR: 1.74; p=0.039), and IPSS (intm-2= HR: 3.19; p=0.057; high risk= HR: 6.83; p=0.001). Scoring values were assigned to each factor based on multivariable HR values (transfusion dependency=1.5; CCI≥3=1; BMI<21=1; intm-2=2 and high risk=4) and three different groups were identified: group1 (0-2 points, 137 pts), group2 (3-5 points, 144 pts) and group3 (5.5-7.5, 62 pts). OS at 3 years was 91.8%, 65.6% and 34.8% in group1, 2 and 3, respectively (log rank p<0.001) for a median OS of undefined, 56.7 and 22.8 months. Notably, while 88.7% of high IPSS risk pts clustered in group3, only 60.5% of pts in group1 were at intm-2 IPSS risk, and 48.6% of pts in group2 were at high IPSS risk. The achievement of a spleen response at 6 months (39.2% *vs* 36.4%, p=0.71) was not influenced by lower BMI. However, pts achieving a spleen response at 6 months significantly increased OS (Fig. 1A). Also, a higher CCI did not correlate with lower spleen response at 6 months (44% *vs* 34% of pts with CCI<3, p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).

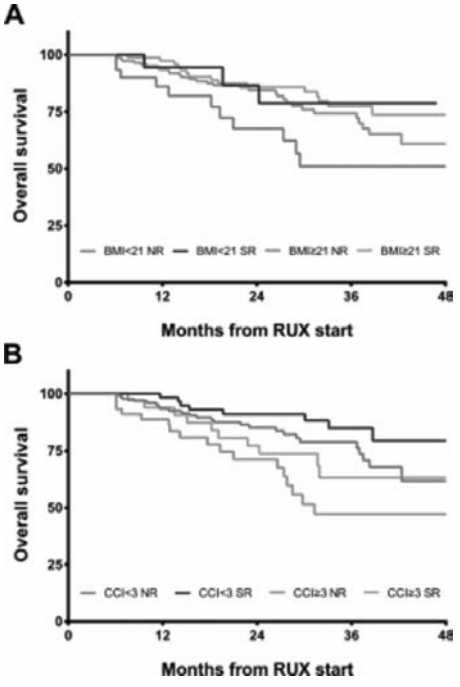

Figure 1.

Summary/Conclusions: Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.

E1326

ANALYSES OF 845 PATIENTS WITH PMF, PET-MF AND PPV-MF TREATED IN 35 GERMAN HEMATOLOGY CENTERS – A RETROSPECTIVE FIELD STUDY

B. Kragl[1,*], C. Wassenberg[2], H. T. Steinmetz[3], G. Springer[4], K. Jentsch-Ullrich[5], A. Gaumann[6], J. Dengler[7], C. Junghanss[1]

[1]Department of internal medicin 3, Hematology, Oncology, Palliative Care, University of Rostock, Rostock, [2]Gefos Dortmund mbH, Dortmund, [3]Gemeinschaftspraxis für Onkologie und Hämatologie, Köln, [4]Hämato-Onkologische Schwerpunktpraxis, Stuttgart, [5]Schwerpunktpraxis für Hämatologie und Onkologie, Magdeburg, [6] Institut für Pathologie, Kaufbeuren, [7]Schwerpunktpraxis Onkologie, Heilbronn, Germany

Background: Primary myelofibrosis (PMF) as well as secondary post essential thrombocythemia (pET)-MF and post polycythemia vera (pPV)-MF are considered rare diseases associated with significant morbidity. Diagnostics and therapeutic options have significantly improved during the last decade by development of novel drugs, improvement of allogeneic stem cell transplantation (SCT) procedures and supportive care. Whereas the characteristics of PMF, pET-MF and pPV-MF patients (pts) participating in clinical trials are well analyzed, data are rare for the general MF population including patients not included in or eligible for clinical trials.

Aims: In order to gain a broader, more comprehensive data set on the general MF population we performed a questionnaire poll in 35 German hematology centers gathering characteristics on 845 pts who were currently under care.

Methods: A questionnaire asking for general patient and disease specific data as symptoms, splenomegaly, prognostic factors, past/ current treatment and blood count, degree of MF in bone marrow and transfusion frequency was designed. It was distributed to participating centers (n=35, mostly private offices) throughout Germany and analyzed centrally. Time period of collection

was 03/2013-12/2015. 845 pts were included *i.e.* a median of 20 pts (range 6–90 pts) per center
Results: Gender was equally distributed (50%/50%). Pts ages at initial diagnosis were as follows:<50 years (y) (11%), 50–60y (19%), 61-70y (31%), and >70y (40%). Current age was >65y in 70% of all pts. PMF represented the largest MF cohort (77%), followed by pET-MF (10%), pPV-MF (7%) and unspecified (6%). Most pts had a longer disease duration (>5y (36%); 1-5y (48%); <1y (15%); unknown (1%)). Key current blood values at time of survey included abnormal thrombocyte counts (<50GPT/l (6%); 50 to <100GPT/l (10%); ≥450GPT/l (28%) and elevated WBC >25.000/µl (11%). Presence of circulating blasts in the peripheral blood was documented in 11% of pts. Hemoglobin [g/dl] was ≥10 (68%), 8–10.0 (21%), <8 (8%), unknown for 3% of the pts. Constitutional symptoms were present in 20% of the pts. Common symptoms included splenomegaly (60%), decreased fitness (41%) and weight loss (16%). Pruritus was present in 5% and night sweats in 9% of all pts. An individual Dynamic International Prognostic Scoring System (DIPPS) score was calculable in 495 pts: 19% low risk, 52% intermediate-1, 23% intermediate-2 and 5% high risk disease. Concomitant diseases were common, most often cardiac (56%). Most common medical treatments included cytostatic (37%), anticoagulation (25%), JAK-inhibitors (23%) and none (24%). Non-medical treatments were rare: stem cell transplantation (3%), splenectomy (2%) and spleen irradiation (3%). Only 31% of all pts received red blood cell transfusions, however 7% had received >50 units.
Summary/Conclusions: Daily practice MF pts share several characteristics with MF trial cohorts (e.g. COMFORT). As expected the diseases were not as progressed as in the trials. Interestingly gender was equally distributed in our study. SCT was a rarely used treatment within this cohort whereas JAK2 inhibitors were frequently used

E1327

CALR MUTATION TYPE INFLUENCES THE RISK OF THROMBOSIS IN ESSENTIAL THROMBOCYTEMIA ACCORDING TO A COOPERATIVE STUDY BETWEEN TWO SPANISH CENTERS

A. Abuín Blanco[1,*], A. Sáez Salinas[2], L. Bao Pérez[1], J.M. González Martín[3], F.J. López Jaime[1], L. Torres Miñana[2], A. Mosquera Orgeira[1], C. Bilbao Sieyro[2], C. Quinteiro García[4], T. González Martínez[4], Y. Florido Ortega[2], C. Ulibarrena Redondo[1], G. Santana Santana[2], M.J. Rabuñal Martínez[1], N. Díaz Varela[1], Á. Bendaña López[1], N. Alonso Vence[1], M.S. González Pérez[1], J.L. Bello López[1], M.M. Pérez Encinas[1], M.T. Gómez Casares[2]
[1]Hematology, Complexo Hospitalario Universitario of Santiago of Compostela, Santiago, [2]Hematology, [3]Statistics and Epidemiology, Hospital Universitario of Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, [4]Molecular biology, Fundación Pública Galega de Medicina Xenómica, Santiago, Spain

Background: "Driver mutations" in Essential Thrombocitemia (ET) involve JAK2V617F, CALR and MPL genes. The mutation profile affect the hematological parameters and the risk of thrombosis being the JAK2V617F mutation the one associated with the higher risk of thrombosis. Among CALR mutations there are two main types: type -1 like and type-2 like, but it is not clear if the mutation type is associated with a different clinical feature
Aims: The objective of this study is to understand the clinical meaning of CALR mutation type in ET
Methods: We analyzed 309 ET patients from two hospitals: H.C.U. Santiago and H.U. of Gran Canaria Dr. Negrin. Dates of diagnosis were between 1-11-90 and 1-10-2016, and the median follow up was of 6.88 years. Patients were treated according to local protocols. We collected clinical data of patients at diagnosis and during follow-up as well as events such as thrombosis, transformation to myelofibrosis (MF) or acute leukemia (AL). Thrombosis associated with diagnosis refers to those events happening from two years before diagnosis until diagnosis. The statistical analyses were performed with R Core Team (2016) and IBM SPSS 21.0
Results: JAK2V617F mutation was present in 60.5% of the patients, 1.9% had MPL mutations, 14.5% were CALR type-1like, 11% were CALR type-2like and 11% were triple negative. In three cases, we were not able to classify CALR mutation as type-1/2 like. With regard to the clinical events: 21 patients (6.8%) had thrombosis associated with diagnosis, and 34 (11%) at least 1 thrombosis since the diagnosis. Twelve patients suffered more than 1 thrombotic event. MF evolution was found in 18 patients (5,6%) and 2 cases transformed to AL. In the analysis of hematological parameters according to the mutation type, when we compared **JAK2V617F *VS* CALR type-1like** we observed that JAK2V617F group showed higher hemoglobin values (mean 13.8g/dL *vs* 13.26 g/dL; p=0.014) and lower platelet counts (mean 730x10^9/L *vs* 884x10^9/L, p=0.001) than CALR type-1like group. Confronting **JAK2V617F *VS* CALR type-2like:** the JAK2V617F group showed a higher leucocyte counts (mean 9.39x10^9vs 8.44x10^9/L, p=0.039) and higher hemoglobin values (mean 13.8g/dL *vs* 12.8g/dL, p<0.001)), but lower platelet counts (730x10^9/L *vs* 1081x10^9/L, p<0.001) as compared with the CALR type-2like group. When we studied **CALR type-1like *VS* CALR type-2like:** the CALR type-2like group showed higher platelet count (1081x10^9/L *vs* 884x10^9/L, p<0.035) than CALR type-1like group. **With regard to the thrombotic events,** frequency of first thrombosis (arterial or venous) was 20.9% (n=39) in the JAK2V617F group, 15.5% (n=7) in the CALR type-1like, and 3% (n=1) in the CALR type-2like group. Frequency of thrombosis was significantly higher in JAK2V617F than in CALR group (p= 0.036) and also in JAK2V617F vs. CALR type-2like (p=0.013). When comparing CALR type-1like *vs* CALR type-2like the differences were marginally significant (p=0.06). In a multivariate analysis with the IPSET variables and CALR subtype, in our series the previous history of thrombosis (p <0.001) and the JAK2V617F status (p=0.026) were significantly associated with increased risk of thrombosis, but no the advanced age neither the presence of cardiovascular risk factors. However, presence of CALR type-2like mutation, with respect to the JAK2V617F mutation, was a protective factor of thrombosis (p= 0.06). The five year-thrombosis free survival (TFS) study was as follows: 83%, 85% and 97% for groups JAK2V617F, CALR type-1like and CALR type-2like (log rank p=0.03)(fig. 1).

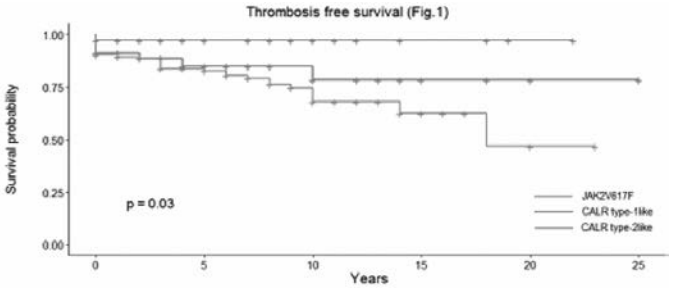

Figure 1.

Summary/Conclusions: The type of driver mutation is associated with a different risk of thrombosis. Among the two types of CALR mutantion, patients have similar clinical characteristics except for the risk of thrombosis which seems lower in CALR type-2like compared to type-1like. This finding shows the importance of studying the CALR mutation type in ET.

E1328

MONITORING OF LEUKOCYTE-PLATELET AGGREGATES AND SELECTIN LEVELS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

D. Šefer[1,*], P. Miljić[1,2], N. Kraguljac-Kurtović[1], S. Bižić-Radulović[1], V. Čokić[3], A. Bogdanović[1,2], D. Marković[3], V. Knežević[1], D. Leković[1,2], M. Gotić[1,2]
[1]Outpatient Clinics and Diagnostic Department, Clinic for Hematology,Clinical Center of Serbia, [2]Faculty of Medicine, [3]Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: Although the reduction of thrombotic risk is a primary goal of therapy in Philadelphia negative myeloproliferative neoplasms (Ph$^-$MPN), even low risk patients (pts) may experience thrombotic events during the course of the disease. Some recent studies revealed a correlation between the occurrence of thrombosis and activation of blood and endothelial cells. However, not many information is available about influence of therapy on these parameters.
Aims: We prospectively analyzed the levels of leukocyte-platelet (Le-Plt) aggregates, together with levels of soluble selectins, in a group of pts with Ph$^-$MPN at diagnosis and during therapy.
Methods: Our study included 90 consecutive *de novo* Ph$^-$MPN pts (37 polycythemia vera, 27 essential thrombocythemia, 26 primary myelofibrosis), diagnosed according to WHO criteria. According to therapy, pts were assigned as: hydroxyurea (HU 7.8%), aspirin (ASP 55.6%), hydroxyurea+aspirin (HU+ASP 31.1%), although 5.6% of pts were without therapy. Neutrophil-platelet (Neu-Plt) and monocyte-platelet (Mo-Plt) aggregates were determined in whole blood samples (EDTA/CTAD) by flow cytometry. Aggregates were estimated as fraction (%) of CD42b$^+$CD61$^+$ neutrophils and monocytes. Plasma levels of E-, L-, and P-selectins were determined by enzyme immunoassay. All analyses were performed on diagnosis, and repeated 6-9 months after the start of therapy (for pts on HU after achievement of partial or complete remission).
Results: In all pts, mean levels of Neu-Plt and Mo-Plt aggregates at diagnosis were significantly elevated in comparison to control values (22.9% *vs* 8.9% and 13.0% *vs* 5.2% respectively, p<0.01). Mean concentration of soluble E-, L- and P-selectins were also significantly higher in Ph$^-$MPN than in control group (34.2 ng/mL *vs* 19.0 ng/mL; 2748.7 ng/mL *vs* 1322.0 ng/mL and 294.0 ng/mL *vs* 69.8 ng/mL, respectively, p<0.01). Mean levels of Neu-Plt and Mo-Plt aggregates in response to therapy were significantly reduced compared to baseline levels (Figure). Significant reductions were observed for E-selectin levels in HU+ASP group, for L-selectin levels in all three therapy groups and for P-selectin levels in HU and HU+ASP groups (Table). During the median follow up of 39 months from diagnosis of Ph$^-$MPN, thromboembolic events occurred in 13.3% of pts (12/90), particularly: 0/7 on HU, 3/50 on ASP, and 9/28 on HU+ASP. In this subgroup we observed increased baseline levels of Neu-Plt and/or Mo-Plt aggregates in 9/12 pts, while all 12 pts had increased at least one soluble selectin, predominantly P-selectin. Retesting revealed that all 9 pts with thrombosis and increased aggregates level at baseline, normalized those levels after therapy, while only 4/12 pts normalized soluble selectin levels.

Table 1.

Soluble selectins, ng/mL (threshold)	HU (n=7)		p	ASP (n=50)		p	HU+ASP (n=28)		p
	baseline	retest		baseline	retest		baseline	retest	
E- (<39.0)	55.8	50.3	0.285	44.1	58.8	0.001	56.1	45.8	0.046
L- (<2491.8)	3608.7	2180.2	0.043	3907.7	3023.1	0.020	3490	2220	0.001
P- (<129.2)	407.9	131.5	0.018	332.2	267.4	0.310	523.3	162.0	0.0001

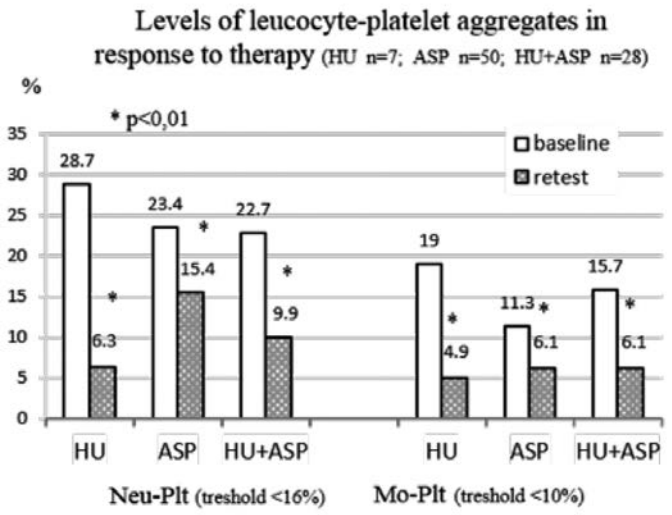

Figure 1.

Summary/Conclusions: We have found elevation of blood and endothelial cell activation markers at baseline in Ph-MPN. Cytoreductive and antiaggregatory therapy reduced the mean level of Le-Plt aggregates and concentration of soluble selectins. In subset of pts with thrombosis, therapy lead to normalization of Le-Plt aggregate levels, with incompletely normalized soluble selectin levels. Even with normal Le-Plt agregates, observed elevated selectin levels can explain persistent thrombotic risk due to intrinsic changes in relationship between blood and endothelial cells as a part of biology of Ph-MPN itself.

E1329

HEAT SHOCK PROTEIN 27 EXPRESSION IS INCREASED IN PATIENTS WITH PRIMARY AND SECONDARY MYELOFIBROSIS AND MAY BE AFFECTING THEIR SURVIVAL

M. Lucijanic[1], A. Livun[2], K.M. Tupek[2], T. Stoos-Veic[3], G. Aralica[4], I. Gecek[4], V. Pejsa[1], R. Kusec[2,*]
[1]Hematology department, [2]Clinical Institute of Laboratory Diagnosis, Divison of Molecular Diagnosis and Genetics, [3]Department of Clinical Cytology and Cytometry, [4]Pathology department, Universitiy Hospital Dubrava, Zagreb, Croatia

Background: Increased heat shock protein 27 (HSP27/*HSPB1*) expression and phosphorylation were observed in a large number of neoplastic diseases and they have mostly been associated with aggressive disease features and poor prognosis. There are only few reports investigating HSP27 in primary myelofibrosis (PMF), a myeloproliferative neoplasm characterized by high inflammatory state reflecting in debilitating clinical symptoms.
Aims: To analyze *HSPB1* mRNA expression in patients with PMF and secondary myelofibrosis (SMF) and to correlate it with clinical and hematological features.
Methods: We analyzed *HSPB1* relative expression in bone marrow aspirates of 26 patients with PMF, four patients with SMF and 13 controls using quantitative real time polymerase chain reaction (RT-PCR). Spleen size was assessed by palpation. Association with overall survival was analyzed in 27 PMF and SMF patients evaluated at the time of diagnosis. The Kuskal-Wallis one way analysis of variance, The Mann Whitney U test, the Chi squared test, the Spearman rank correlation, the log-rank test and the Cox regression analysis were used, cut-off point for survival analyses was determined using the ROC curve analysis.
Results: Relative expression of *HSPB1* differed significantly between diagnoses (P<0.001); it was significantly higher in patients with PMF and SMF than in control group (P<0.05 for both comparisons), but did not differ between PMF and SMF patients (non significant). Increased expression was associated with increase in the spleen size (P=0.009) and *JAK2* V617F mutation (P=0.073). We did not detect significant associations with other disease specific features. Lower *HSPB1* expression was associated with inferior overall survival in both univariate (HR 3.2; P=0.04) and multivariate analysis (HR 6.12; P=0.034) where effect was independent of age (non significant), gender (non significant) and the International Prognostic Scoring System (IPSS) score (HR 3.31; P=0.033).

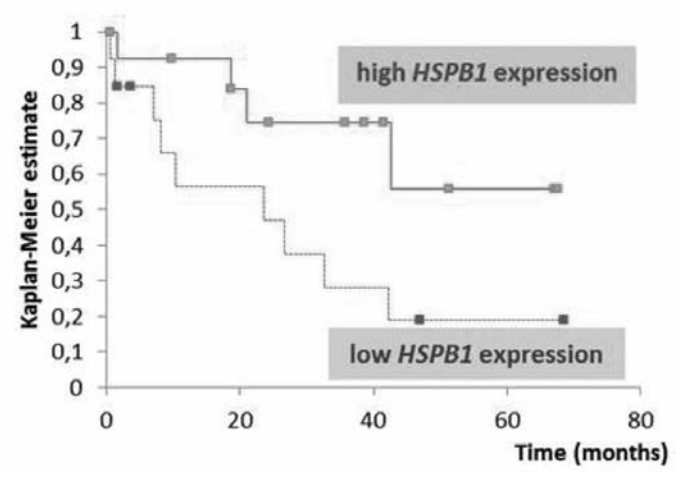

Figure 1.

Summary/Conclusions: Both PMF and SMF patients have increased *HSPB1* mRNA expression in their bone marrows which is associated with increased spleen size. Surprisingly, higher expression is also associated with improved overall survival which is independent of IPSS score. We speculate this to be due to atheroprotective properties of HSP27.

E1330

NON-DRIVER MUTATIONS IDENTIFIED BY A 190-GENE NEXT GENERATION SEQUENCING PANEL IN PATIENTS WITH PRIMARY MYELOFIBROSIS AND POST-POLYCYTHAEMIC/ESSENTIAL THROMOCYTHAEMIA MYELOFIBROSIS

B. Li[1,*], Z. Xu[1], T. Qin[1], Y. Zhang[1], J. Liu[1], Z. Xiao[1]
[1]MDS and MPN Centre, Institute of Hematology and Blood Diseases Hospital Chinese Academy of Medical Sciences, Tianjin, China

Background: It is a consensus that the driver mutation is an independent prognostic factor in PMFs. Moreover, some non-driver mutations are found associated with initiation, progression and prognosis in PMFs. However, a recent study from the AGIMM (AIRC- Gruppo Italiano Malattie Mieloproliferative) group showed that the type of driver mutation did not influence prognosis in post-PV/ET MF. These observations proved that there were indeed some differences in these two types of MF.
Aims: The aim of current study was to describe the non-driver mutation landscape and the molecular differences between the patients with PMF and those with post-PV/ET MF.
Methods: Targeted gene sequencing was carried out at diagnosis. We sequenced 190 genes across 62 patients, resulting in 229 high-confidence mutation. The average gene coverage was 99%. The average read depth was 540×. Also, 92% of targeted regions were covered with >20×. Every mutation identified in this study was then compared against these expected patterns and categorized into “oncogenic,” “possible oncogenic variants,” or “unknown significance”. Using copy number-adjusted VAF, we reconstructed the clonal architecture to establish whether a mutant gene was an ancestral or subclonal mutation. According to the statistically differences in VAF among gene mutations, subjects were classified as two different clonal architecture, namely clone+subclone(s) (P<0.05) or clonal.
Results: In PMFs, 42 (93.3%) patients had at least one non-driver mutation. Within the 17 patients lacking the driver mutations in *JAK2V617F*/exon 12, MPLW515 and CALR, 2 had mutant genes (SH2B3 and PIAS3) involving in JAK-STAT pathway, 13 had mutations in other genes and 2 had no mutations. In Post-MFs, non-driver mutations were detected in 16 (94.1%) patients. There are no differences in the median number of non-driver mutations in PMFs *vs.* post-PV/ET MFs (3 *vs.* 3.18, *P*=0.885) and PMF patients with *vs.* without driver mutations (3 *vs.* 3.18, *P*=0.668). In PMFs, 12 non-driver genes were mutated in >5% of patients, namely *ASXL1* 33.3%, *U2AF1* 22.2%, *TET2* 15.6%, *FAT1* 15.6%, *SETBP1* 13.3%, *SRSF2* 8.9%, *CUX1* 8.9%, *EP300* 8.9%, *FAT2* 6.7%, *NOTCH3* 6.7%, *EZH2* 6.7%, and *GATA3* 6.7%. In post-PV/ET MFs, *ASXL1* (41.2%) was the most frequent mutation, followed by *TET2* (29.4%). *U2AF1* and *SRSF2* mutations were significantly more frequent in PMF than in post-PV/ET MF. Moreover, *SETBP1* and *FAT1* were mutated in PMF more often and not mutated in post-PV/ET MF. Figure1 A-C show 3 illustrative patients. Clonal architecture was significantly different between PMFs and post-PV/ET MFs (Figure 1D). About 50% PMF patients were classified as clonal, however, most (87.5%) post-PV/ET MF patients were clone+subclone(s). In PMFs, driver mutation was an ancestral mutation with other non-driver mutations in 14 (31.1%) subjects as 2015-R02413 in Figure 1A. Moreover, driver mutation even was a subclonal mutation in 9 (16.7%) subjects as 2015-R02406 in Figure

1B. In post-PV/ET MFs, 11 (64.7%) subjects showed that JAK2 mutation as an only ancestral mutation as G121517R00701 in Figure 1C.

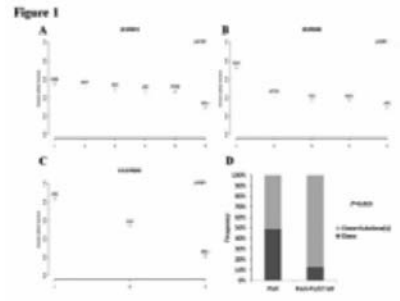

Figure 1.

Summary/Conclusions: In conclusion, we found that the differences in non-driver mutation profile and clonal architecture between PMF and post-PV/ET MF. In addition, by applying a 190-gene panel we demonstrated some variants classified as of "unknown significance". And larger sample sizes may enable some of these to be reclassified in the future. The precise role of each mutation and their impact on MPN phenotype will require further studies.

E1331

DETERMINING MEANINGFUL CHANGE IN THE MYELOFIBROSIS SYMPTOM ASSESSMENT FORM (MFSAF) V2.0 USING A COMBINATION OF DISTRIBUTION- AND ANCHOR-BASED APPROACHES IN THE COMFORT-I TRIAL

A. Dueck[1,*], R. Scherber[2,3], H. Kosiorek[1], B. Langlais[1], L. Padrnos[3], J. Palmer[3], S. Verstovsek[4], J. Sloan[5], G. Holly[3], R. Mesa[3]
[1]Mayo Clinic, Scottsdale, AZ, [2]Oregon Health and Science University, Portland, OR, [3]Mayo Clinic, Phoenix, AZ, [4]MD Anderson, Houson, TX, [5]Mayo Clinic, Rochester, MN, United States

Background: Symptom response was defined in the COMFORT-I trial as a 50% improvement from baseline at week 24 in the Myelofibrosis Symptom Assessment Form (MFSAF) v2.0 total symptom score (TSS; Mesa [J Clin Onc, 2013]; 0 to 60 scale where 60 represents the worse symptom experience imaginable) with no minimum score requirement at baseline.
Aims: In this analysis of the phase III placebo-controlled COMFORT-I study we used distribution- and anchor-based approaches to investigate whether alternative change scores in the MFSAF v2.0 TSS could be meaningful relative to patient-reported quality of life (QOL).

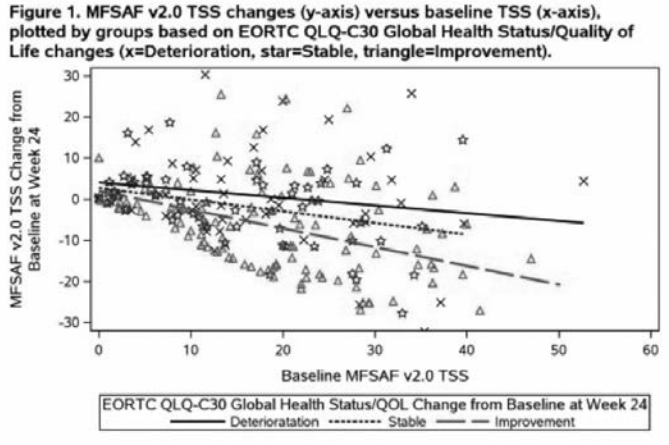

Figure 1.

Methods: One third and one half of the pooled standard deviations (SD) of scores and change scores (raw and percentage change) were used as distribution-based estimates. The anchor-based approach estimated meaningful changes (raw and percentage change) relative to the patient's change in global health status/QOL (GH/QOL; 0=worst, 100=best) as measured by the EORTC QLQ-C30 where a decrease of 12.1 or more points was considered as deterioration; an increase of 7.6 or more points was considered as improvement; and all other changes were considered as stable based on change scores established in a multiple myeloma population (Kvam et al., Eur J Hem, 2011). Analysis of covariance (ANCOVA) was used to investigate whether estimated meaningful changes were consistent across the spectrum of observed baseline TSS. This model of TSS changes at week 24 included a continuous term for baseline TSS, a 3-level grouping factor for GH/QOL change (deterioration *vs* stable *vs* improvement), and an interaction term between baseline TSS and the GH/QOL grouping factor.
Results: 301 patients randomized to ruxolitinib [N=149] or placebo [N=152] completed TSS at baseline (45% female, median age 68 [range 40-91]). Median baseline TSS was 16.6 (range 0 to 52.7). Pooled SD at baseline and week 24 in TSS was 11.4 and 11.6, respectively, resulting in estimated meaningful changes of 3.8-5.8 points. For change and percentage change from baseline at week 24 in TSS, the pooled SDs were 9.8 and 75%, respectively, resulting in estimated meaningful changes of 3.3-4.9 points or 25%>38%. Among patients with TSS and QLQ-C30 data at baseline and week 24, 51 (23%) patients had deterioration, 61 (27%) were stable, and 110 (50%) had improvement based on QLQ-C30 GH/QOL changes. Mean (95% CI) changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.6 to 0.8), and -6.8 (-9.0 to -4.6), and for percent changes 20% (-6% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%). ANCOVA revealed that baseline TSS statistically significantly impacted meaningful change estimates (p=0.02, Figure 1) resulting in estimated mean (95% CI) changes in TSS for the improved group of -20.8 (-26.4 to -15.1), -11.7 (-14.3 to -9.0), and -2.6 (-5.1 to -0.1) for baseline TSS of 50, 30, and 10.
Summary/Conclusions: Distribution- and anchor-based approaches suggest that changes as small as 3-6 points on a 0-60 scale of the MFSAF v2.0 TSS may be meaningful to patients. However, estimates of meaningful change appear to increase in magnitude for higher baseline scores, though in a way that a static percentage change criterion would either require too much change for lower baseline TSS or not enough change for higher baseline TSS. All analyses suggest that some changes in symptoms which do not meet a 50% improvement may still be meaningful to patients.

E1332

ERYTHROPOIESIS STIMULATING AGENTS CAN IMPROVE ANEMIA IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

E. Crisà[1,*], C. Daniela[2], E.M. Elli[3], E. Beggiato[1], C. Frairia[4], M. Cerrano[1], G. Lanzarone[1], M. Marchetti[5], M. Mezzabotta[6], M. Boccadoro[1], D. Ferrero[1]
[1]Hematology Division, A.O.U. Città della Salute e della Scienza di Torino,University of Turin, [2]Department of Clinical and Biological Sciences, University of Turin, Torino, [3]Hematology Division, Ospedale San Gerardo, ASST Monza, Monza, [4]Hematology, A.O. Ospedale Maggiore di Novara, Novara, [5]SOC Oncologia, Ospedale Cardinal Massaia, Asti, [6]Hematology Division, Ordine Mauriziano - Ospedale Umberto I, Torino, Italy

Background: Anemia is common in patients with myelofibrosis (MF) and it is one of the main cause of symptoms in this setting. Erythropoiesis stimulating agents (ESA) have been used in MF but mostly small series and no randomized trials have been published so far. Anemia response rate ranged between 23 and 60% in different reports (Cervantes et al, BJH 2004;Cervantes et al, BJH 2006;Tsiara et al, Acta Haematologica 2007) and a larger study recently published by Cervantes group on 163 patients (Hernandez-Boluda JC. E et al, EJH 2016) showed a response rate of 50%. Ruxolitinib is currently approved for the treatment of intermediate 2 or high DIPSS/IPSS risk MF and it is highly effective in reducing spleen size and controlling the symptoms of MF, thus resulting in a marked improvement in the patients' quality of life (Verstovsek S. et al, NEJM 2012; Harrison C. et al, NEJM 2012) and possibly a prolonged survival (Cervantes F. et al Blood 2016). However, one of ruxolitinib main side effects is anemia, which occurs in 40% of the patients and can be a limiting factor for treatment tolerability and thus compliance and optimal dosage, mostly in the first weeks of treatment.
Aims: To evaluate the efficacy and safety of combination therapy with ruxolitinib and ESA.
Methods: We retrospectively evaluated 32 patients who received concomitant therapy with ruxolitinib and ESA. ESA (epoetin alpha or zeta or darbepoetin) were given off-label after obtaining patient written consent and local pharmacy approval. Erythroid response was defined as transfusion independence with normal haemoglobin (HB), transfusion decrease of >50% or sustained HB increase of >2g/dl, partial response as a sustained HB increase of 1-2g/dl.
Results: We included 32 patients diagnosed with MF, 23,1% primary,34,6% secondary to PV and 42,3% to TE. 20 patients (62,5%) were male and median age at ESA start was 70 years (range 41-80). 87% of patients were at intermediate 2 and 13% at high risk according to DIPSS. Fifty-nine% of patients received epoetin alpha, 28% darbepoetin and 13% epoetin zeta. Median dose for epoetin alpha/zeta was 40000 U/week and for darbepoetin 150 mcg/week. Seven patients had started ESA treatment before ruxolitinib therapy, whereas twenty-five patients received erythropoietin after ruxolitinib start for persisting or worsening of anemia. In particular, 5 were already RBC transfusion dependent before commencing ruxolitinib while 13 patients required red blood cell (RBC) transfusions only after treatment start. Overall ruxolitinib treatment worsened anemia leading to RBC transfusion requirement in 52% of patients. Median Hb at ESA start was 8 g/dL(range 6,2-10g/dL) and 62,5% of patients were transfusion dependent. Median basal endogenous erythropoietin level was 58 UI/l (range 8-146 UI/l). Overall response rate was 87,6%, with 68,8% of erythroid response and 18,8% of partial response. Median time to response and median

response duration were 4 and 31 months respectively. 23% of patients lost response after a median time of 16 months. Seventy-five% of patients responded to ruxolitinib in terms of spleen size, of whom 86,4% also achieved an erythroid response to ESA. A spleen increase during ESA treatment in patients responding to ruxolitinib was observed in 2 patients only.
No thrombotic events and no toxicity were reported over treatment with ESA.
Summary/Conclusions: ESA were effective in improving anemia in MF patients treated with ruxolitinib. We observed a high response rate in this patients series without significant toxicities. In particular no thrombotic event e no negative impact on response to ruxolitinib was reported. This results may be partially explained by the selection of patients with endogenous erythropoietin level below 250 UI/l, but they could also suggest synergistic activity of ESA and ruxolitinib.

E1333

COMPARING THE SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH DIPSS LOW/INTERMEDIATE-1–, INTERMEDIATE-2–, AND HIGH-RISK MYELOFIBROSIS (MF) IN JUMP, A PHASE 3B, EXPANDED-ACCESS STUDY

F. Passamonti[1,*], V. Gupta[2], B. Martino[3], L. Foltz[4], A. Zaritksey[5], H.K. Al-Ali[6], R. Tavares[7], M. Maffioli[8], P. Raanani[9], P. Giraldo[10], M. Griesshammer[11], C. Bouard[12], J. Perez Ronco[12], R. Tiwari[13], A. M. Vannucchi[14]

Ltd, Hyderabad, India, [14]CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that led to improvements in splenomegaly and symptoms and increased overall survival in pts with intermediate (Int)-2– and high-risk MF by the International Prognostic Scoring System (IPSS) in the phase 3 COMFORT studies. JUMP is a large, phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with IPSS Int-1–, Int-2–, and high-risk MF. To further evaluate RUX, we conducted an analysis assessing safety and efficacy of RUX by Dynamic IPSS (DIPSS) prognostic risk.
Aims: To compare the safety and efficacy of RUX in pts with DIPSS low/Int-1–*vs* Int-2– *vs* high-risk MF
Methods: Eligible pts had IPSS high- or Int-2–risk MF, or Int-1–risk MF and a palpable spleen (≥5 cm). Starting dose was based on baseline platelet (PLT) count (5mg bid [≥50 to <100×10^9/L], 15mg bid [100-200×10^9/L], or 20mg bid [>200×10^9/L]) and could be titrated during treatment. The primary endpoint was safety and tolerability of RUX. Changes in palpable spleen length and symptom scores were also assessed. DIPSS scores were determined using pt characteristics at baseline.
Results: Based on available pt data, DIPSS status was determined for 1840 of 2233 enrolled pts. JUMP included 893 low/Int-1–, 754 Int-2–, and 193 high-risk pts (primary MF, 57%, 63%, 62%) who started treatment ≥1 y before data cutoff (01 Jan 2016). Pts with higher-risk MF were older (62, 68, and 72 y), had lower Hb (<10 g/dL, 3%, 64%, 100%), and had higher blast counts (≥1%, 18%, 44%, 84.5%). Disease duration (50, 51, and 55 mo) and spleen size (12, 13, and 14.5 cm) were similar in all 3 groups. Most pts started at 20mg bid (68%, 57%, 59%) or 15mg bid (26%, 32%, 33%). Median exposure was 16, 11, and 9 mo; mean average daily dose was 30, 28, and 29mg. At data cutoff, most pts remained on treatment or had completed per protocol (70%, 56%, 45%). Main reasons for treatment discontinuation included adverse events (AEs; 15%, 17%, 27%), disease progression (6%, 11%, 11%), and death (2%, 5%, 11%). The most common hematologic grade 3/4 AEs were anemia (22%, 44%, 55%) and thrombocytopenia (11%, 18%, 25%), but these rarely led to discontinuation. Overall rates of nonhematologic grade 3/4 AEs were <2%, except for pneumonia (4.5%), pyrexia (2.3%), asthenia (2.2%), and dyspnea (2.2%). Infections in ≥5% of pts were pneumonia (7.3%), urinary tract infection (6.1%), and nasopharyngitis (5.3%). Herpes zoster was reported in 4.8% of pts. At wk 48, 64% (226/355), 52% (121/232), and 50% (26/52) of pts had a ≥50% reduction from baseline in spleen length; 19% (68/355), 19% (43/232), and 23% (12/52) had 25%-50% reductions. Best response in spleen length by wk 72 is shown in the **Figure**; 69%, 57%, and 51% of pts achieved ≥50% reductions. Median time to response was 4.7 wk (2.9-75 wk), 5.3 wk (2.6-80 wk), and 8.1 wk (3.1-72.3 wk). From wk 4 to 48, 39%-43%, 41%-44%, and 48%-54% of pts achieved a clinically meaningful response on the FACT-Lym TS; proportions of responders on the FACIT-Fatigue were 42%-49%, 46%-49%, and 55%-61%.

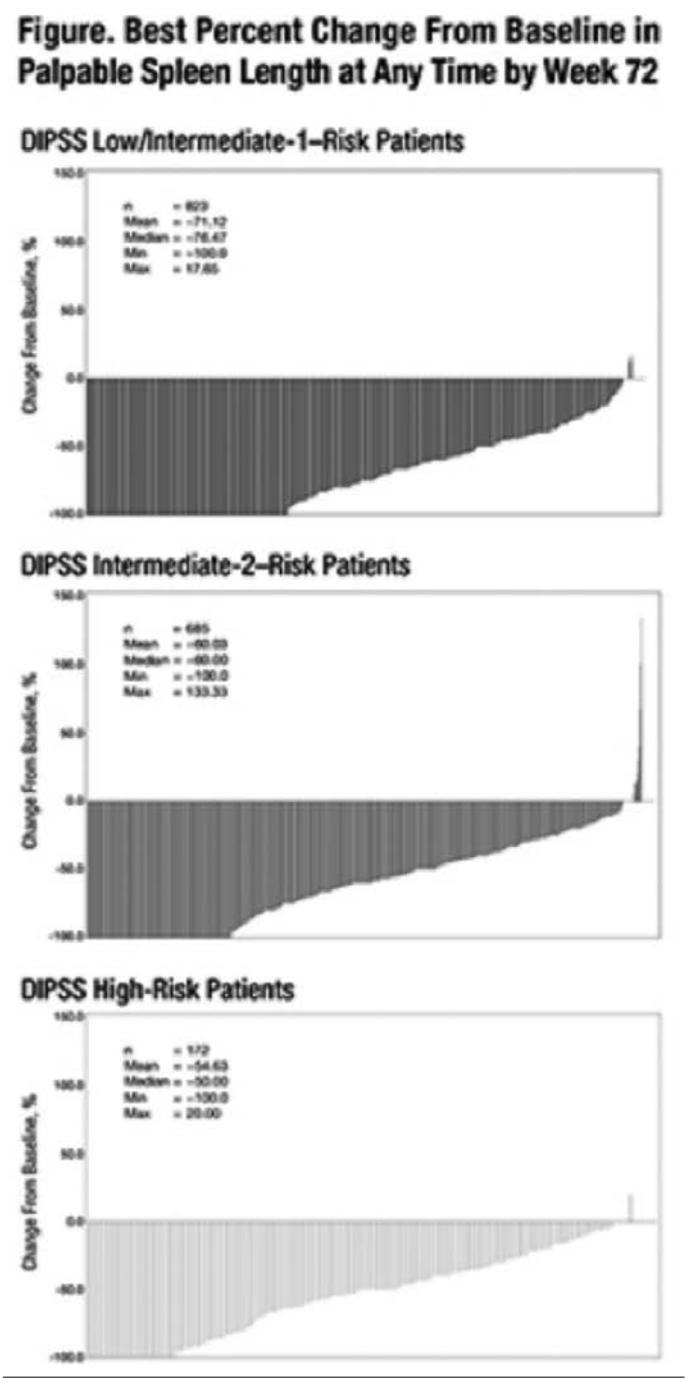

Figure 1.

Summary/Conclusions: RUX was safe and generally well tolerated. Interestingly, lower-risk pts received higher starting doses yet had lower rates of hematologic AEs. Additionally, lower-risk pts remained on treatment longer than higher-risk pts, with fewer discontinuations due to AEs. Lower-risk pts also achieved slightly better spleen size reductions and symptom improvement than higher-risk pts, suggesting that earlier RUX treatment may lead to greater benefits in pts with MF.

E1334

SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS WITH MYELOFIBROSIS (MF) WHO STARTED TREATMENT AT 10mg BID AND HAD THE DOSE UPTITRATED IN THE PHASE 3B EXPANDED-ACCESS JUMP STUDY

L. Foltz[1,*], B. Martino[2], A. Zaritksey[3], R. Tavares[4], P. Giraldo[5], H.K. Al-Ali[6], P. Guglielmelli[7], V. Gupta[8], P. Raanani[9], C. Bouard[10], J. Perez Ronco[10], R. Tiwari[11], M. Griesshammer[12]

abria, Italy, [3]Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, [4]Universidade Federal de Goiania, Goiania, Brazil, [5]Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, [6]University Hospital of Halle, Halle (Saale), Germany, [7]CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, [8]Princess Margaret Cancer Centre, Toronto, Ontario, Canada, [9]Rabin Medical Center, Petah Tikva, Israel, [10]Novartis Pharma AG, Basel, Switzerland, [11]Novartis Healthcare Pvt. Ltd, Hyderabad, India, [12]Johannes Wesling Clinic, Minden, Germany

Background: JUMP is a phase 3b, expanded-access trial that assessed the safety and efficacy of RUX in pts with no access to RUX outside of a clinical trial. Pts received RUX at 5, 15, or 20mg bid per protocol. Increasing evidence from clinical practice suggests that starting RUX at 10mg bid and subsequently uptitrating may reduce the risk of cytopenia development. An *ad hoc* analysis of a subset of JUMP pts provides information on this approach.
Aims: To assess the safety and efficacy of RUX at a starting dose of 10mg bid in pts with MF.
Methods: Pts with high-, Int-2–, or Int-1–risk MF were eligible. Int-1–risk pts had a palpable (≥5 cm) spleen. Protocol starting doses (5, 15, or 20mg bid) were based on baseline platelet (PLT) counts (≥50 to <100×10^9/L, 100 to 200×10^9/L, >200×10^9/L, respectively). Although not per protocol, some pts started RUX at 10mg bid. The primary endpoint was safety. Secondary endpoints included changes in spleen length and symptoms.
Results: A total of 48 pts (primary MF, 60%) started RUX at 10mg bid ≥1 y before data cutoff (01 Jan 2016). Mean baseline characteristics were: median age, 65.5 y (range, 20-83 y); male, 44%; spleen length, 12.3 cm; time since diagnosis, 56.6 mo; hemoglobin (Hb), 112.1 g/L (<100 g/L, 33.3%); PLT count, 351×10^9/L (<100×10^9/L, 10.4%). Pt characteristics were similar to those of the overall population and did not indicate an increased risk of developing cytopenias. At data cutoff, most pts remained on treatment or had completed treatment per protocol (58.3%). Primary reasons for treatment discontinuation included adverse events (AEs), disease progression, and death (8.3% each). Overall, 41.7% of pts had dose modifications (AEs, 33.3%); 20.8% had interruptions (all due to AEs). Median exposure was 14.4 mo. The mean average daily dose was 25.8mg/day (SD, 10.1) and was comparable to those (33.2 and 23.3mg/day) of patients starting at higher doses (20 and 15mg bid; **Figure**). The most common hematologic grade 3/4 AEs were anemia (27.1%; overall, 34.1%) and thrombocytopenia (14.6%; overall, 16.3%). Hb and PLT dynamics were also similar. AEs (all-grade [grade 3/4]) in >10% of pts included pyrexia (14.6% [4.2%]), asthenia (12.5% [0%]), weight increase (12.5% [0%]), abdominal pain (10.4% [0%]), headache (10.4% [2.1%]), and peripheral edema (10.4% [0%]). Infections in >2 pts included herpes zoster (8.3%), gastroenteritis, nasopharyngitis, and septic shock (6.3% for each). At wk 24, 60.9% of pts (14/23) had a ≥50% reduction from baseline in spleen length and 26.1% (6/23) had 25%-50% reductions; rates were similar at wk 48 (58.3% [7/12] and 25.0% [3/12]). Most pts (56.3%) achieved a ≥50% reduction at any time. Pts also experienced significant improvements in symptoms. From wk 4 to 48, 43%-59% and 45%-68% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACIT Fatigue, respectively.

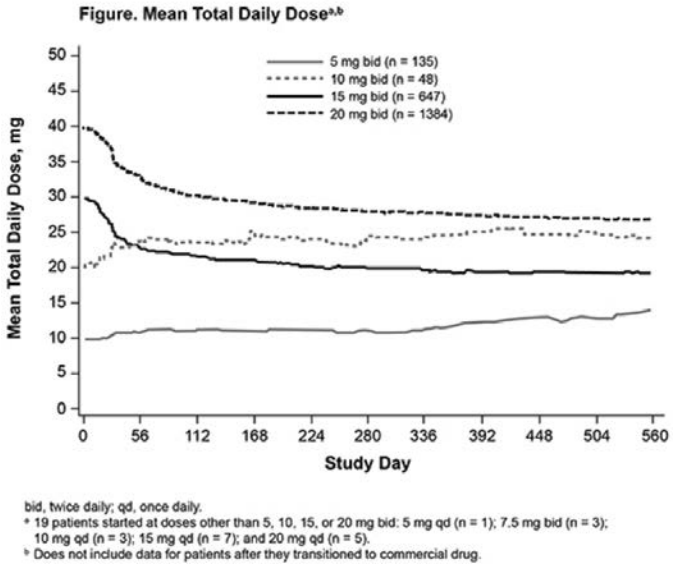

Figure 1.

Summary/Conclusions: A small cohort of pts in JUMP started at 10mg bid, and had the dose uptitrated during the first 8 wks to a mean average daily dose comparable to those of pts starting at higher doses, leading to safety and efficacy outcomes consistent with those in the overall JUMP population. This alternative approach will be prospectively evaluated in anemic MF pts in the REALISE study (NCT02966353).

E1335

HYDROXYUREA IS ASSOCIATED WITH SKIN TOXICITY IN MYELOPROLIFERATIVE NEOPLASMS: RESULTS FROM A PROSPECTIVE NON-INTERVENTIONAL STUDY

F. Stegelmann[1,*], K. Wille[2], S. Schauer[1], H. Döhner[1], K. Döhner[1], M. Griesshammer[2]
[1]University Hospital of Ulm, Ulm, [2]University of Bochum, Minden, Germany

Background: Until today, hydroxyurea (HU) remains the most commonly used cytoreductive drug in patients (pts) with classic myeoproliferative neoplasms (MPN), *i.e.* essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF). However, mucosal lesions, cutaneous ulcers, and pre-carcinomatous skin alterations such as actinic keratoses are being considered as potential side effects of HU.
Aims: We sought to investigate the occurrence of skin toxicity in MPN pts under HU compared to other (non-HU) cytoreductive drugs in routine clinical practice.
Methods: Classic MPN pts regularly presenting at the outpatient centers of the University Hospital of Ulm and Johannes Wesling Clinic Minden were included in our non-interventional study after having given informed consent. Skin alterations were evaluated prospectively between December 2010 and November 2016.
Results: In total, 151 MPN pts under cytoreductive therapy were included (ET, n=55; PV, n=55; MF, n=41). Primary MPN diagnosis was made between 1979 and 2012 at a median age of 55 years (range, 22-82). Median duration of the disease until baseline of the study was 6.3 years (0-32.6). Median prospective observation time for the total cohort within the study period was 5.3 years (0.4-6.2). Most frequently used cytoreductive drugs were HU in 120 pts, followed by ruxolitinib in 59, anagrelide in 39, and pegylated Interferon-alpha (IFN-a) in 28 pts. Median cumulative HU exposure was 46 months (1-252), while the median cumulative treatment time for the corresponding drug in the 126 non-HU pts was 24 months (1-267) [ruxolitinib: 22 months (2-64); anagrelide: 19 months (1-216); IFN-a: 64 months (1-267)]. Of 120 pts exposed to HU, 52 pts (43%) presented with skin abnormalities during the observational period occurring after a total HU treatment time of median 46 months (1-252). Sixteen of 120 pts (13%) discontinued HU due to skin toxicity such as skin ulcers (n=6), phototoxicity / erythrodermia (n=5), actinic keratoses (n=3), dry skin / xerostomia (n=2). Of note, four malignant skin diseases were reported under HU therapy (basal cell carcinoma, n=3; malignant melanoma, n=1). Although pts of the HU cohort were exposed longer to the drug compared to pts of the non-HU group, numbers of skin events in non-HU treated pts were as following: n=5 under anagrelide (skin ulcers, n=2; allergic reaction, n=2; basal cell carcinoma, n=1), n=4 under IFN-a (local reaction after subcutaneous injection, n=3; actinic keratosis, n=1), and none under ruxolitinib. In 3/126 (2%) non-HU treated pts, occurrence of skin toxicity led to discontinuation of the corresponding cytoreductive drug. Interestingly, both skin ulcers as well as the single events ´basal cell carcinoma´ and ´actinic keratosis´ occurred under combination therapy with HU. Taken together, skin alterations occurred more frequently under HU compared to non-HU treatment (52/120 [43%] *vs* 9/126 [7%]; p=0.0001), and the same was true for treatment discontinuations due to skin toxicity (16/120 [13%] *vs* 3/126 [2%]; p=0.014).
Summary/Conclusions: According to our prospective observation, skin toxicity was clearly associated with HU treatment compared to other cytoreductive drugs. This resulted in a higher rate of HU treatment termination due to skin toxicity. However, median exposure time to HU was longer compared with non-HU treatment, and controlled clinical trials are necessary to provide more precise data on the occurrence and severity of skin toxicity under HU.

E1336

THE NEGATIVE PROGNOSTIC IMPACT OF BASOPHILIA, EOSINOPHILIA AND MONOCYTOSIS AT DIAGNOSIS IN PRIMARY MYELOFIBROSIS

M. Pereira[1,2,*], K. Hundarova[2], J. Carda[1,2], E. Cortesão[1,2], R. Guilherme[1,2], L. Ribeiro[1], A.-B. Sarmento-Ribeiro[1,2]
[1]Clinical Hematology Department, Coimbra University Hospital Centre, [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Primary myelofibrosis (PMF) is a myeloproliferative neoplasm (MPN) with a variable clinical presentation, from asymptomatic disease to rapidly progressive bone marrow failure and/or leukemic transformation; prognostic stratification using the DIPSS-plus score isolates patient cohorts with median survivals ranging from 16 months to 185 months. The development of monocytosis during the course of PMF has been associated with a worse outcome, and absolute monocyte counts have been shown to be of prognostic value in other MPNs. Basophilia and eosinophilia are frequent findings in BCR-ABL-

positive MPNs, where they associate with an accelerated phase of disease, and seem to correlate with worse survival in myelodysplastic syndromes. However, the impact of these three findings at diagnosis in PMF remains unclear.
Aims: The aim of this work is to evaluate, at diagnosis, the prognostic impact of basophilia, eosinophilia and monocytosis in patients with PMF.
Methods: We identified all PMF patients diagnosed and followed-up in our Center between January 1st 2005 and August 31st 2016 who still fulfill PMF criteria under the WHO 2016 diagnostic revision, have synchronous bone marrow (BM) and peripheral blood (PB) analyses dating from the time of diagnosis, and have complete charts with no missing data. After the exclusion of reactive causes, monocytosis was defined as an absolute count (AC) >1.0 G/L, eosinophilia as an AC>0.6 G/L and basophilia as an AC >0.2 G/L.
Results: We studied 55 evaluable patients (73% male) with a median age at diagnosis of 70.1±11.7 years old. At diagnosis, 20% of patients had **monocytosis**, with no significant differences according to gender or age. The median overall survival (OS) in PMF patients with monocytosis was 27.3 months, and twice as long (46.4 months) in patients without. In this cohort, a new calculated cut-off of 0.75 G/L was better able to stratify patients according to survival with a specificity of 74.1% (95% CI: 53.7-88.9%); 32.7% of patients had an AC above the cut-off, with a median OS of 27.9 months, compared to 64.4 months for patients under the cut-off. We identified 12.7% of patients with **eosinophilia** at diagnosis, with no differences according to gender or age. PMF patients with eosinophilia had a five-fold lower median OS compared with patients without (6.1 *vs* 32.5 months, respectively). We obtained a new cut-off of 0.25 G/L of eosinophils, which separated patients with a specificity of 77.8% (95% CI: 57.7-91.4%); 29.1% of patients had an eosinophil AC above the cut-off, with a median OS of 27.3 months, compared to 43.6 months for patients under the cut-off. A total of 30.9% of patients had **basophilia** at diagnosis, with no differences according to gender or age. The median OS in patients with basophilia was 25.6 months, and 32.5 months in patients without. With a new cut-off of 0.25 G/L of basophils, with a specificity of 88.9% (95% CI: 70.8-97.64%), 20.0% of patients had a basophil AC above the cut-off and a median OS of 19.7 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocyte, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-offs, this difference in OS increased to 27.9 *vs* 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.
Summary/Conclusions: We observed that the presence of monocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also associated with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.

E1337

BLAST PHASE IN PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS OF 85 PATIENTS

E. Roncoroni[1,*], M. Bellini[2], E. Rumi[1,2], V. Ferretti[1], D. Pietra[1], C. Cavalloni[1], M. Ciboddo[2], I. Casetti[2], P. Zappasodi[1], P. Benvenuti[2], C. Astori[1], M. Cazzola[1,2]
[1]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [2]Department of Molecular Medicine, University of Pavia, Pavia, Italy

Background: Classic Ph-negative myeloproliferative neoplasms (MPN) include essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). Clonal evolution can lead MPN patients in chronic phase (CP) to develop acute myeloid leukemia (AML), called blast phase (BP): this event occurs at rates of approximately 1% in ET, 4% in PV and 20% in PMF over the first decade from MPN diagnosis.
Aims: To evaluate differences in clinical features and outcome in 85 patients with MPN in blast phase, according to MPN diagnosis and mutational profile.
Methods: We identified in our database all patients affected with ET, PV and PMF who developed acute myeloid leukemia according to 2016 WHO criteria (≥ 20% blasts in bone marrow or peripheral blood) and for whom at least one DNA sample to define the mutational status of the three MPN driver genes (*JAK2*, *CALR*, *MPL*) was available. Treatment used in blast phase was classified as palliation (supportive care only or low intensity chemotherapy) or induction chemotherapy (de novo AML-like therapy).
Results: We retrospectively identified among 2902 consecutive patients affected with Ph-negative MPN 85 patients who progressed to BP, with a known molecular profile: 26 ET patients of whom 15 presented *JAK2 V617F* mutation, 8 *CALR* mutation, 1 *MPL* mutation, 1 *JAK2/MPL* mutation and 1 was triple-negative, 36 PV patients all *JAK2*V617F mutated, and 23 PMF patients of whom 17 were *JAK2* mutated, 2 *CALR* mutated, 2 *MPL* mutated and 2 triple-negative. Median age at BP was 71,3 years (range 46,3-86), being higher in PV (median 73 years, range 46,3-84,7) compared to ET (median 68,7 years, range 54,4-86, *P* 0,318) and PMF (median 67,9 years, range 48,1-84,9, *P* 0,016). The complete blood count at leukemic evolution was not influenced by the initial diagnosis. At the time of BP, 31 out of 44 patients (70%) for whom cytogenetic analysis was available showed an abnormal karyotype (22 patients with complex karyotype or high risk aberrations). *JAK2* mutated MPN can evolve into *JAK2* wild type AML (9 of 28 patient with blasts DNA available), while *CALR* mutation was identified also in AML blasts in all 6 patients for which DNA was available. Time to leukemic evolution was shorter in PMF (35,3 months, range 3,6-141,1) compared to ET (176,7 months, range 14,4-362,3, *P* <0,001) and PV (129,1 months, range 17-367,6, *P*<0,001). According to chronic phase driver mutation, time to leukemic evolution was shorter in *JAK2 V617F* mutated PMF compared to *CALR* mutated PMF (30,6 *vs* 138 months, *P* 0,024), but not statistically different in *JAK2* mutated ET compared to *CALR* mutated ET (123,4 *vs* 203,2 months, *P* 0,121). Outcome was dismal, independently from MPN diagnosis (P 0,278), with a median overall survival (OS) of 3,9 months (range 3,3-5,6). OS was not influenced by treatment during blast phase (4,5 months with induction chemotherapy *versus* 4,6 months with palliation; P 0,865). Of the whole series, only one patient is alive and in complete clinical and molecular remission, after 11 months from allogeneic bone marrow transplantation.

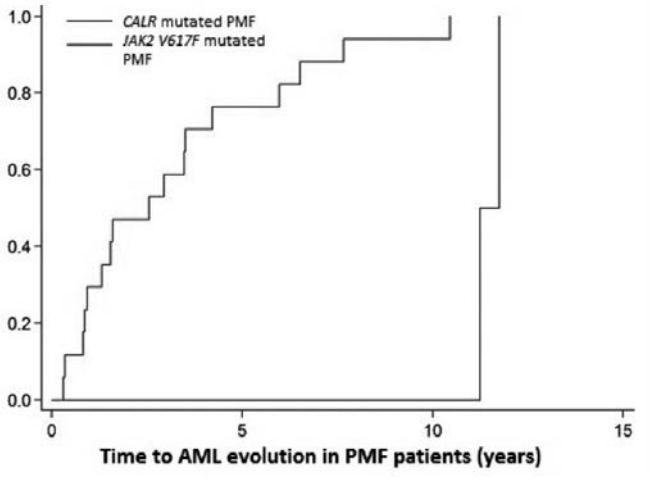

Figure 1.

Summary/Conclusions: Clinical phenotype and outcome of BP is not influenced neither by the diagnosis in chronic phase nor by the driver mutation; moreover the outcome is poor irrespective of treatment. PMF patients have a shorter time to BP than ET and PV patients; in PMF *JAK2 V617F* mutation is associated with a shorter time to BP compared to *CALR* mutation. The only potentially curative treatment is represented by allogeneic stem cell transplantation, but only a few patients can actually undergo this procedure.

E1338

TELOMERE LENGTH IS REDUCED IN ESSENTIAL THROMBOCYTHAEMIA PATIENTS COMPARED TO AGE AND GENDER MATCHED HEALTHY CONTROLS

S. Alimam[1,*], J. Jie[2], D. McLornan[2], D. Radia[1], G. Mufti[2], C. Harrison[1]
[1]Haematology, Guys and St Thomas' NHS Foundation Trust, [2]Haematology, King's College London, London, United Kingdom

Background: Essential thrombocythaemia (ET) is a clonal stem cell disorder, commonly diagnosed in the 6th or 7th decade of life. ET is associated with risk of thromboembolic events, hemorrhage, constitutional symptoms, progression to myelofibrosis and acute myeloid leukemia. In over 85% of patients a clonal driver can be identified with mutations in *JAK2* (50-60%%), Calreticulin (*CALR*) (25-30%) or the thrombopoetein receptor (*MPL*) (3-5%); the remainder of patients are termed "triple negative" (TN). Telomeres are non-coding regions of DNA consisting of thousands of repeated sequences (TTAGGG) and are considered central to chromosomal integrity and genomic stability. In healthy adults, telomere length (TL) progressively shortens with age; therefore, TL is considered a marker of aging and genome instability. Hematopoietic cells in several hematological malignancies have been shown to be characterized by shortened TL.
Aims: Determine if there is TL shortening in patients with ET when compared to age and gender matched controls and establish the effects of cytoreductive on TL in ET patients.
Methods: 100 patients were included in the study (27 with *CALR*, 35 *JAK2*V617F and two MPL515W mutations. 36 patients were TN). Most patients were female (70% 70/100); median age was 45 years (range 20 - 86 years).

TL was determined in peripheral blood mononuclear cells using a monochrome multiplex quantitative PCR based on the original methods described by Cawthon. All results were corrected for age and gender.
Results: Regardless of driver mutation status ET patients had significantly shortened TL compared with age and gender matched controls, p=<0.0001. Considering individual mutation status these differences remained significant *e.g. CALR* positive, p=0.0009; *JAK2*V617F positive p=0.007 and p=0.012 in TN patients. TL appeared more markedly short in the *CALR* cohort; for the 18 patients, whose TL was below the first centile, 55% (10/18) were *CALR* positive *vs* 28% (5/18) *JAK2*V617F positive *vs* 17% (3/18) who were TN. Concerning the potential impact of therapies 31/100 patients were treated with hydroxycarbamide (HC); 24/100 interferon (IFN) (eight of these had prior exposure to HC); 34/100 were not on cytoreductive therapy. Remaining treatments were ruxolitinib (5), busulphan (4), anagrelide (1) and vorinostat (1). Independent of mutation status there was significant TL shortening in untreated patients, p=0.05; however, upon evaluating the impact of cytoreductive therapy on TL we noted that ET patients with either current, or prior HC treatment had significantly shortened TL, p= 0.0015 and p=<0.0001 respectively. Strikingly, there was no significant difference in TL in IFN patients who had no previous exposure to HC, p=0.2 but those ET patients currently on IFN but with prior HC exposure still had shorter TL, p=<0.0001.
Summary/Conclusions: We document for the first time that ET patients, when compared to age and gender matched healthy controls, have shortened TL. This shortening is more pronounced in *CALR* and *JAK2* V617F positive patients. Concerning therapy whilst present in untreated patients TL shortening was more pronounced in HC treated patients indicating that there may be a therapy effect as has been observed after HC treatment in sickle cell disease. Of note IFN treated patients had more normal TL suggesting that the disease related TL effects may be reversed by this agent.

E1339

NUTRITION IN MYELOFIBROSIS: CORRELATES FROM THE COMFORT-1 STUDY

R. Scherber[1,2,*], H. Kosiorek[3], H. Geyer[4], S. Verstovsek[5], B. Langlais[3], L. Padrnos[1], J. Palmer[1], A. Dueck[3], A. Fleischman[6], R. Mesa[1]
[1]Hematology and Oncology, Mayo Clinic, Scottsdale, [2]Hematology and Oncology, Oregon Health and Science University, Portland, [3]Biostatistics, [4]Internal Medicine, Mayo Clinic, Scottsdale, [5]Hematology and Oncology, MD Anderson, Houston, [6]Hematology and Oncology, University of California Irvine, Irvine, United States

Background: Nutritional status declines in most patients with myelofibrosis (MF). Sixty-seven percent of patients with MF lose weight over time and 27% of patients have a BMI decrease of at least one body mass index (BMI) category (Mesa *et al.* Blood. 2008;112(11):5224). MF also leads to deficient LDL and cholesterol levels compared to age matched controls (Mesa R A *et al.* Blood. 2007;110(11):2548). Both hypocholesterolemia (p<0.001) and weight loss>10% (p<0.001) have been associated with decreased survival in PMF patients (Mesa *et al.* Blood 2009 114:3918) JAK inhibitor therapy has been found to improve nutritional markers including weight, cholesterol, albumin, and leptin compared to placebo in the COMFORT-1 study (Mesa *et al.* Clin Lymphoma Myeloma Leuk. 2015 Apr; 15(4): 214–221; Verstovsek *et al.* N Engl J Med 2012; 366:799-807). However, the corelation of these factors with other disease related variables and overall survival has not been established.
Aims: To evaluate the correlation, if any, between nutritional markers other variables collected in the COMFORT-1 study.
Methods: Data from the COMFORT-1 trial of ruxolitinib *versus* placebo was obtained from the Incyte for independent analysis. Data was analyzed for correlation with symptom burden and survival along with other variables. Symptom burden was assessed by the MF-SAF v2.0 (Mesa *et al.* Leuk Res 2009) for individual items and total symptom score (TSS).
Results: A total of 309 patients were available for analysis including 155 ruxolitinib-treated and 154 placebo-treated MF patients. At baseline, the average BMI was 24.9 (SD=4.5). Baseline demographic and other disease-related variables can be found in previous publications (Verstovsek *et al.* N Engl J Med 2012; 366:799-807). Correlatives: *Baseline*: For all patients at baseline, numerous correlations between baseline nutritional markers and markers of nutrition (Figure 1) were identified. Total Symptom Scores (TSS) inversely correlated with albumin, cholesterol, alpha-feto protein, HDL, and serum erythropoietin levels. Baseline leptin levels correlated with many items including BMI, albumin, cholesterol, LDL, erythropoietin, insulin and CRP. *Placebo*: For patients treated with placebo, changes in BMI inversely correlated with changes in CRP (r=-0.22, p=0.04). Positive correlations were observed between changes in LDL with cholesterol (r=0.87, p<0.001) and HDL (0.41, p<0.001). In addition to LDL, HDL change inversely correlated with TSS score (-0.24, p=0.02), and positively correlated with changes in bone pain (0.23, p=0.02), abdominal fullness (r=0.22, p=0.02), erythropoetin levels (0.27, p=0.01) and cholesterol levels (r=0.39, p<0.001). *Ruxolitinib*: Most correlations with nutritional and metabolic markers mirrored with baseline scores (Figure 1b). For ruxolitinib-treated patients, change in JAK2V617F mutational status inversely correlated with changes in serum cholesterol (-0.26, p=0.008), leptin (-0.38, p<0.0001), and LDL (-0.23, p=0.02). CRP changes were inversely correlated with change in cholesterol levels (-0.18, p=0.03).

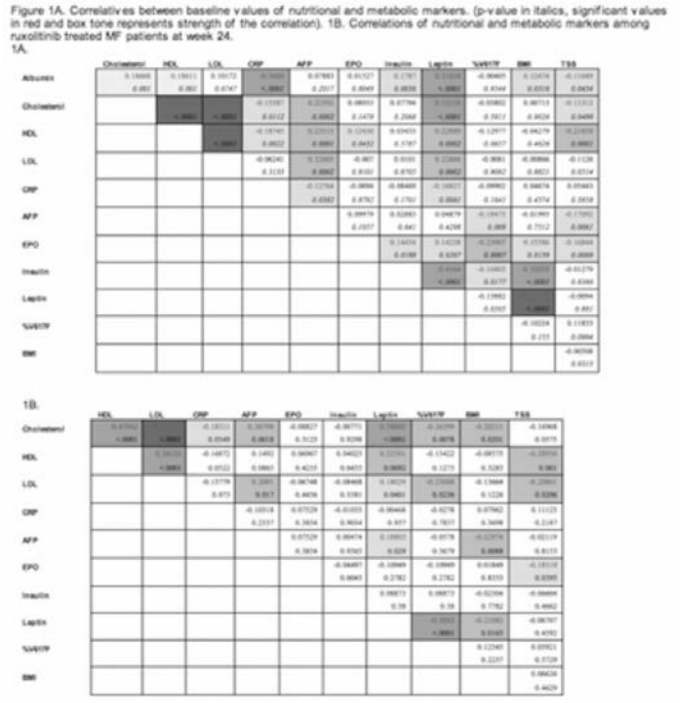

Figure 1A. Correlatives between baseline values of nutritional and metabolic markers. (p-value in italics, significant values in red and box tone represents strength of the correlation). 1B. Correlations of nutritional and metabolic markers among ruxolitinib treated MF patients at week 24.

Figure 1.

Summary/Conclusions: Nutrition decline remains an unmet need for many MF patients. JAK2 inhibition represents a potential source to improve symptom burden in those who qualify for therapy. Leptin closely correlated with many other nutritional values suggesting this may be a good marker of nutritional status in MPN patients. CRP was inversely correlated with BMI, suggesting the importance of inflammation as a contributor to weight loss. Further study into the unique nutritional needs of myelofibrosis patients is warranted.

Giovanni Addolorata Hospital, Roma, [16]Department of Hematology, Polo Universitario Pontino, Latina, [17]Department of Cellular Biotechnology and Hematolog,, University "La Sapienza", [18]Department of Cellular Biotechnology and Hematology, University "La Sapienza", Rome, Italy

Background: To evaluate the prognosis of patients with Essential Thrombocythemia (ET) in the first decade of the century we assessed retrospectively the thrombosis free survival (TFS) and the overall survival (OS) of the patients diagnosed from 01/01/2000 to 31/12/2009 and collected on the database of our group.
Aims: Diagnosis of ET was performed with PVSG, WHO 2001 or 2008 criteria, according to the date of the first observation. The whole population of 757 patients was then divided in two groups: the first (group I) with the diagnosis performed between 01/01/2000 to 31/12/2005 (334 patients), presented a median follow-up of 111,9 months, the second (group II) diagnosed between

01/01/2006 to 31/12/2009 (385patients), with a median follow-up of 58,2 months.
Methods: The characteristics of two groups of patients are reported in the Table 1. No differences could be found between the two groups according age, gender, platelet and WBC count and Hb level, Cardio-Vascular Risk Factors (CVRF), spleen enlargement and the occurrence of previous thrombotic events. The frequency of the JAK-2 ^{V617F} mutation resulted significantly different (49.1% *vs* 68.4%) but in the group I the search of the mutation was never performed at the diagnosis. TFS and OS were calculated from the date of diagnosis of ET to the date of event with Kaplan-Meier product limit method; the comparison of proportions and median values was computed with the Chi-squared and the Mann-Withney tests, as indicated.
Results: No significant differences emerged neither for TFS (p= 0,09, HR 1,42, 95% C.I. 0.89-2.30) nor for OS (p= 0,15, HR 1,34, 95% C.I. 0,87-2,06). We also evaluated the type of treatment used in the two groups to assess the potential link between the therapy and TFS or OS (Table 2). No difference emerged between the two groups as for anti-aggregating (mainly ASA), equally utilized in both groups, 287/369, 77,8%, and 330/383, 78,3%, respectively (p=0,95). As for the cytoreductive therapy, Hydroxyurea was used in 74.8% *vs* 67.9% (p= 0.60) and alkylating agents in 1.9% *vs* 2.1% (p= 0.85), whereas the Anagrelide resulted utilized in 10,6% *vs* 3,9% (p= 0,001) and Interferon in 9,5% *vs* 5,2% (p= 0,037), respectively. The more frequent use of Anagrelide and Interferon in the first group (2000-2005) didn't modify the prognosis (as for TFS and OS) of the patients.

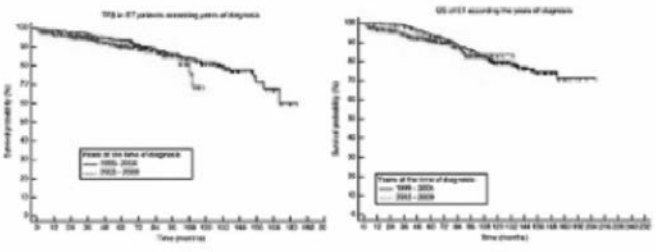

Figure 1.

Summary/Conclusions: Unfortunately, no improvement, neither as the TFS nor the OS was observed (Fig. 1 and 2): more efforts to better identify the groups at risk and, hopely, the introduction of new drugs as JAK-2 inhibitors could change the prognosis of ET patients.

E1341

CUTANEOUS INVOLVEMENT IN PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS-SINGLE-CENTER EXPERIENCE

J. M. Sanchez-Raga[1,2,*], N. Knöpfel[3], M.D.M. Escudero-Góngora[3], F. Sartori[2], B. Lopez[1,2], I. Herraez[2], M.D.C. Ballester[2], M. Torres[2], A. Martin-Santiago[3], A. Sampol[2], M.A. Durán[2]
[1]Hematology and Hemotherapy, Fundación de Investigación Sanitaria de las Islas Baleares Ramon Llull, [2]Hematology and Hemotherapy, [3]Dermatology, Hospital Universitari Son Espases, Palma de Mallorca, Spain

Background: Philadelphia-negative chronic myeloproliferative neoplasms (MPNs) may present clinical dermatological manifestations at the time of diagnosis, as well as during the course of the disease. On the other hand, also its treatments can present skin side effects.

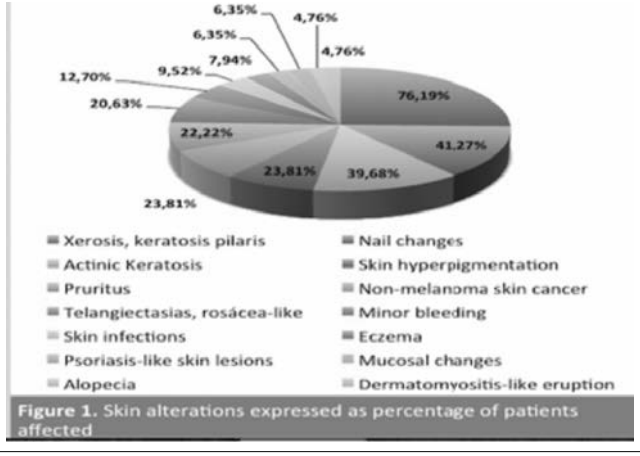

Figure 1. Skin alterations expressed as percentage of patients affected

Figure 1.

Aims: We have performed a dermatological review of a cohort of patients we follow-up at our center with the aim of assessing the cutaneous manifestations.
Methods: A randomized selection of patients with a diagnosis of essential thrombocythemia and polycythemia vera was performed. We create a specific consultation in which a detailed history of each patient (sex, age, diagnosis, signs and symptoms, treatments and its duration) as well as a deep dermatological examination was done. All data was collected in an Excel database and analyzed using the SPSS system.
Results: 63 patients (54 ET and 9 VP) were reviewed. The most frequent skin lesions were xerosis and/or keratosis pilaris (76.2% patients), nail changes (41.3%), actinic keratosis (39.7%), hyperpigmentation of the skin (23.8%), pruritus (23.8%) and non-melanoma skin cancer (22.2%). In figure 1 we detail all the skin alterations that we have found.
Summary/Conclusions: Cutaneous involvement in MPNs is more frequent than expected and it is usually underdiagnosed. Some of these lesions could be prevented with the correct treatment of their pathology and adequate photoprotective measures. The results obtained support the recommendation of an annual review by a dermatologist in a systematic way, especially in patients with higher risk factors: low phototype, high sun exposure, past dermatological history and prolonged cytoreductive therapy.

E1342

HEMOGLOBIN AND WHITE CELL COUNT IN PATIENTS CLINICALLY SUSPECTED TO HAVE ESSENTIAL THROMBOCYTHEMIA MAY HELP IN PREDICTING EARLY PRIMARY MYELOFIBROSIS OR UNCLASSIFIABLE MYELOPROLIFERATIVE NEOPLASM

S. Sirhan[1,*], C. Ross[2], A. Orazi[3]
[1]Jewish General Hospital Montreal, Montreal, [2]McMaster University, Hamilton, Canada, [3]Weill Cornell Medical College, New York, United States

Background: Classification of myeloproliferative neoplasms (MPN) in patients presenting with thrombocytosis can be challenging. Relying only on clinical features may lead to misclassification of patients in the early stages of primary myelofibrosis (PMF) as essential thrombocythemia (ET). Although bone marrow (BM) biopsy examination is the gold standard necessary for accurate classification, in clinical practice it might be helpful to identify among patients with a working diagnosis of ET those most likely to have early PMF or unclassifiable MPN (MPN-U). To this end, Carobbio *et al. (Am J Hematol. 2012;87:203-4)* developed a simple algorithm based on presence of anemia (hemoglobin <120 g/L for females and <130g/L males) and/or leukocytosis (leukocytes ≥13x10^9/L) or elevated LDH (>200 mU/mL). For an accurate classification, the clinical and laboratory features need to be correlated with BM findings, thus collaboration between hematologists and pathologists is essential.
Aims: To examine applicability of the Carobbio algorithm in routine practice and its potential use in identifying among patients presenting with thrombocytosis and clinically suspected to have ET, those with early PMF or MPN-U. To identify unmet needs in the diagnosis of MPNs in daily practice upon which further educational initiatives can be built which stress the importance of hematologist-pathologist collaboration.

Figure. Program Overview

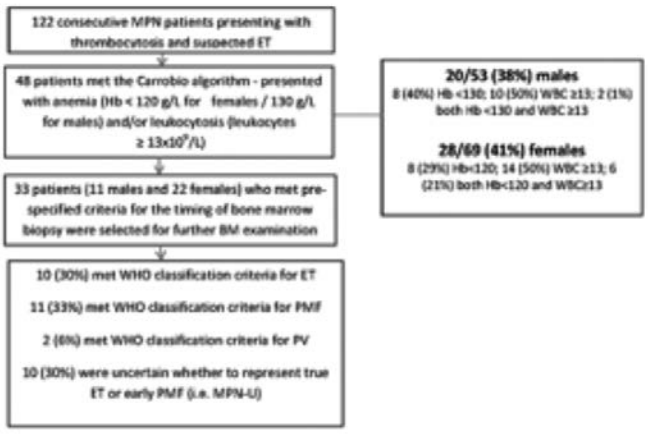

Figure 1.

Methods: A retrospective Personal Practice Assessment Program was conducted at 8 Canadian institutions. Eight hematology/pathology pairs reviewed charts of about 20 consecutive examined patients who presented with thrombocytosis and suspected to have ET. The first 5 out of 20 cases who met the Carobbio algorithm were selected for BM evaluation. To avoid the impact of treatment and/or natural disease evolution on accurate classification, the requirement was for the BM biopsy to be collected within a year of patient's

presentation with thrombocytosis. No central pathology review was planned for this stage of the study.
Results: A total of 122 patients (58 males and 69 females; 54% >60 years of age; 65% with LDH ≥200 mU/mL) with a clinical history indicative of ET were initially assessed. A majority of patients (76%) presented with suspected ET within the last 5 years, likely because it was more difficult for clinicians to identify patients with BM biopsy collected within a year of presentation with thrombocytosis if they presented more than 5 years ago. Out of 122 patients, 48 met the hemoglobin and/or leukocytes criteria outlined in the Carobbio algorithm, Figure. The BM examination was performed on 33 patients who met pre-specified criteria for the timing of bone marrow biopsy. About one third of the 33 patients met the WHO classification for ET and one third for PMF. While 2 of the remaining patients met criteria for PV, the rest were uncertain whether to represent true ET or early PMF, *i.e.* represented MPN-U (Figure 1).
Summary/Conclusions: Despite its methodological limitations, this initiative confirms that in real world clinical practice the Carobbio algorithm can be used to identify possible cases of early PMF and MPN unclassifiable among patients clinically suspected to have ET. It suggests a need for educational initiatives on using diagnostic algorithms to separate ET from PMF. It confirms the importance of hematologist-pathologist collaboration in reaching a final integrated diagnosis based on the WHO classification. These findings warrant further investigation in larger prospective studies.

E1343

PK/PD MODELING COMPARING DIVIDED DOSING (200mg TWICE-DAILY [BID]) *VS* SINGLE DOSING (400mg ONCE-DAILY [QD]) OF PACRITINIB (PAC) IN PATIENTS WITH MYELOFIBROSIS (MF) ON THE PERSIST-2 PHASE 3 TRIAL

S. Al-Fayoumi[1,*], J. Mascarenhas[2], R. Hoffman[2], M. Talpaz[3], A.T. Gerds[4], B. Stein[5], V. Gupta[6], A. Szoke[7], M. Drummond[8], A. Pristupa[9], H. Zhou[1], R. Daly[1], J.A. Callahan[1], J.W. Singer[1], J. Gotlib[10], C. Jamieson[11], C. Harrison[12], R. Mesa[13], S. Verstovsek[14]

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly and debilitating constitutional symptoms. At the present, the JAK inhibitor ruxolitinib is the only therapy for patients (pts) with MF that has garnered regulatory approval. Although ruxolitinib has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias, and not indicated for pts with platelets <50,000/μL. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R. Using data from early-phase PAC studies, population PK modeling and simulations predicted that BID dosing would result in higher steady-state AUC and lower Cmax *vs* QD dosing, which may be associated with increased efficacy and comparable or improved safety. Thus, the phase 3 PERSIST-2 trial of PAC *vs* BAT (including ruxolitinib) in pts with MF and platelet counts ≤100,000/μL evaluated both PAC 400mg QD and 200mg BID dosing schedules. Data previously presented (Mascarenhas, J. *et al. Blood*, 128(22), LBA-5.) showed significantly higher spleen volume reduction (SVR) with PAC (QD and BID pooled) *vs* BAT (P=0.001); despite identical cumulative dosing, pts had improved SVR and total symptom score (TSS) reduction with PAC 200mg BID *vs* PAC 400mg QD, with numerically fewer adverse events and a trend towards improved survival.
Aims: Validate the clinical utility of PK/PD modeling to select the PAC 200mg BID regimen in pts with MF treated in the PERSIST-2 trial.
Methods: Pts with MF and baseline platelet count ≤100,000/μL were randomized 1:1:1 to PAC 400mg QD, PAC 200mg BID, or BAT. Blood samples were collected from PAC-treated pts for PK and PD analysis at a prespecified subset of trial sites. Blood samples were collected on day 1 of week 1 (4 h post-dose), week 3 (pre-dose and 4 h post-dose), week 12 (pre-dose), and week 24 (pre-dose). At the remaining sites, blood samples were collected from PAC-treated pts for PK analysis only at weeks 12 and 24 (pre-dose).
Results: In total, PK samples were collected up to week 24 from 144 PAC-treated pts (78 BID, 64 QD). The PK of PAC was described by a 2-compartment model with first order absorption, first order elimination from the central compartment, and an absorption lag time. PAC QD was associated with higher Cmax and lower Cmin *vs* PAC BID (Table). Median PAC plasma concentrations during week 1 were 47% higher with QD *vs* BID dosing. At steady-state, median Cmin ($Cmin_{ss}$) at weeks 12 and 24 were higher with BID *vs* QD dosing by 10% and 15%, respectively. Also, median observed steady-state 4-h concentration at week 3 (coincides with $Cmax_{ss}$) was 12% higher with QD *vs* BID dosing. In an exposure-response analysis, with QD or BID dosing, no trends were detected for a relationship between observed $Cmin_{ss}$ and death, cardiac death, hemorrhagic death, hemorrhagic events, thrombocytopenia (grade ≥2 or ≥3), anemia (grade ≥2 or ≥3), or gastrointestinal events (any grade, grade ≥2, or ≥3). Eleven (15%) and 13 (17%) PAC QD pts achieved SVR ≥35% and TSS reduction ≥50% at week 24, respectively, *vs* 16 (22%) and 24 (32%) PAC BID pts. Treatment with PAC BID but not QD showed a trend of increased SVR *vs* $Cmin_{ss}$.

Table 1.

Table. PAC Exposure

	PAC Regimen	n	Geometric Mean (ng/mL)	Ratio	90% CI
$Cmin_{ss}$	200 mg BID	83	6783	1.12	0.95-1.31
	400 mg QD	76	6076		
$Cmax_{ss}$	200 mg BID	94	8290	0.93	0.77-1.12
	400 mg QD	86	8930		

Summary/Conclusions: As predicted by PK modeling and simulations analyses, PAC 400mg QD was associated with higher Cmax and lower Cmin *vs* PAC 200mg BID in pts with MF from the PERSIST-2 trial. These differences appear to translate into an improved benefit/risk profile of PAC BID *vs* QD regimens.

E1344

ZMYM2-FLT3 IS A RARE, RECURRENT, CYTOGENTICALLY CRYPTIC FUSION IN MYELOID/LYMPHOID NEOPLASMS WITH EOSINOPHILIA THAT IS RESPONSIVE TO FLT3 INHIBITION

M. Jawhar[1,*], N. Naumann[1], M. Knut[2], B. Schneider[3], M. Ghazzawi[2], K.-A. Kreuzer[3], M. Hallek[3], A. Fabarius[1], J. Score[2], A. Chase[2], W. Tapper[2], A. Reiter[1], N. Cross[2]
[1]Department of Hematology and Oncology, Medical Faculty Mannheim of University of Heidelberg, Mannheim, Germany, [2]Faculty of Medicine, University of Southampton, Southampton, United Kingdom, [3]Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Myeloid/lymphoid neoplasms with eosinophilia are characterised by diverse tyrosine kinase (TK) fusion genes, many of which can be effectively targeted by small molecule inhibitors. More than 70 TK fusions have been described, most of which are associated with visible cytogenetic abnormalities. However these fusions are rare, and the pathogenesis of the great majority of cases presenting as myeloproliferative neoplasm with eosinophilia (MPN-eo) remains unexplained. We hypothesized that some MPN-eo cases may be driven by hitherto undetected cryptic TK fusion genes.
Aims: To screen cases with MPN-eo for TK fusion genes and evaluate the significance of any novel fusions
Methods: PolyA RNA extraction from MPN-eo cases, RNA-Seq library preparation and 100bp paired-end sequencing was performed with multiplexing for a minimum of 75 million reads/sample using an Illumina HiSeq 2000. Bowtie, TopHat and TopHat-Fusion were used to align reads, resolve splice junctions, identify and filter potential TK fusions. Confirmation and screening of fusions was performed by RT-PCR and Sanger sequencing.
Results: Of 20 cases tested by RNAseq analysis, just one cryptic TK fusion was identified: *ZMYM2-FLT3*, predicted to arise as a consequence of an 8Mb inversion at 13q12. Unusually, both breakpoints fell within exons (*ZMYM2* exon 20 and *FLT3* exon 14, respectively) resulting in an in frame fusion. To test if this fusion might be recurrent, we analysed 105 additional cases by RT-PCR. One additional positive case was detected, with similar but not identical breakpoints to the initial case. Case 1, a 48 year old female, presented with leukocytosis ($30x10^9$/L), eosinophilia ($2x10^9$/L, elevated serum tryptase (37μg/l), splenomegaly and a hypercellular bone marrow (BM). Cytogenetics was normal and *FIP1L1-PDGFRA*, *KIT* D816V and *JAK2* V617F were all negative and no pathogenetically relevant mutations were identified by a myeloid NGS panel (28 genes). After 10 months, she progressed to myeloid blast phase. Because the disease was resistant to AML-induction chemotherapy (FLAG-Ida), an allogeneic PBSCT from an unrelated donor was performed 13 months after diagnosis. As a consequence of chronic GvHD and septic shock, the patient died 6 months after allogeneic PBSCT. The *ZMYM2-FLT3* fusion gene was identified post mortem. Case 2, a 47 year old male, presented with eosinophilia ($4.7x10^9$/L, 47%) elevated serum tryptase (42μg/l) and a hypercellular BM Cytogenetics was normal and *FIP1L1-PDGFRA*, *KIT* D816V and *JAK2* V617F were all negative. There was no response on steroids or hydroxyurea. Following the finding of *ZMYM2-FLT3* positivity, treatment with sunitinib was commenced. Blood counts started to improve from day 4 and normalized after 3 weeks. During a pause of 3 weeks due to pulmonary infection, leukocytes/eosinophils rapidly increased, but normalized again within weeks after restart of sunitinib. The patient has been maintained on sunitinib for 10 months (since re-start) and remains in complete hematologic remission.
Summary/Conclusions: *ZMYM2* is the fourth gene reported to fuse to *FLT3* in myeloid neoplasms but the first *FLT3* fusion that is cytogenetically cryptic. Patients with *ZMYM2-FLT3* may be amenable to treatment with FLT3 inhibitors and thus, although very rare, this fusion should be considered in the work up of MPN-eo cases. Due to their extensive diversity, we anticipate that RNAseq will become the method of choice to detect rare TK fusions.

E1345

COMPLETE HEMATOLOGIC AND CYTOGENETIC RESPONSE IN A PATIENT WITH FIBROBLAST GROWTH FACTOR RECEPTOR 1 ACTIVATED MYELOPROLIFERATIVE NEOPLASM RECEIVING INCB054828

N. Daver[1,*], V. Subbiah[1], E. Asatiani[2], S. Verstovsek[1]
[1]MD Anderson Cancer Center, Houston, TX, United States, [2]Incyte Europe, Geneva, Switzerland

Background: Fibroblast Growth Factor Receptor (FGFR) inhibitors have demonstrated efficacy in solid tumors with FGFR pathway activation. INCB054828, a novel, highly selective FGFR1, FGFR2, and FGFR3 inhibitor, is being assessed for the treatment of several advanced malignancies (AACR 2015; Abstract 771). 8p11 myeloproliferative syndrome is an aggressive myeloproliferative neoplasm **(**MPN) associated with *FGFR1* translocation on chromosome 8p11.
Aims: To describe the characteristics of a patient with FGFR1 activated MPN who achieved a complete hematologic and cytogenetic response with INCB054828 in an ongoing phase 1/2 trial (NCT02393248)
Methods: In this 3-part, phase 1/2 dose-escalation and expansion trial, eligible adults had any advanced solid tumor (parts 1 and 3) or malignancy with FGF/FGFR alteration (part 2), had Eastern Cooperative Oncology Group performance status score ≤1 (part 1) or ≤2 (parts 2 and 3), and were refractory to prior therapy with no known effective standard therapy available to them. Patients received INCB054828 orally on a 21-day cycle (2-weeks on/1-week off) starting at 9mg QD and increasing to 13.5mg QD.
Results: This 51-year-old male patient with 8p11 translocated MPN diagnosis (currently the only patient with MPN enrolled in this trial), presented with abnormal white blood cell (WBC) count (eosinophils, 15%; peripheral blood [PB] blasts, 4%) and abnormal platelet count (68×10^9/L). The patient had prior therapy with hydroxyurea. Bone marrow (BM) biopsy at study entry showed 95% cellularity, 4% BM blasts, decreased megakaryocytes, t(8,9)(11.2,q33) in 19 of 20 metaphases, and European Myelofibrosis Network grade MF-1. After 6 weeks of treatment with INCB054828 at a dose of 9mg QD in part 2 of the study, WBC count normalized with disappearance of eosinophilia and PB blasts. BM biopsy demonstrated a normalization of bone marrow differential with 50% cellularity, 1% BM blasts, adequate trilineage hematopoiesis, MF-1 fibrosis, and a **complete cytogenetic response**. After 4 months of treatment the patient was hospitalized for pneumonia and study treatment was held. The patient progressed to AML shortly after therapy interruption, with BM blasts increasing to 83% and evidence of clonal evolution (47,XY: +8 t(8,9) (11.2;q33) [3]/48 idem, +19 [17]). The patient was taken off study at this time (end of cycle 6) and subsequently achieved a complete remission on intensive chemotherapy with fludarabine, cytarabine, idarubicin, and allogeneic BM transplantation. The patient is currently alive and in complete remission.
Summary/Conclusions: INCB054828 showed efficacy in this patient with FGFR1 activated MPN using a 21-day (2-weeks on/1-week off) regimen. Continuous treatment may be necessary to sustain response and avoid rebound as has been seen with other kinase inhibitor therapies. A phase 2 trial has been initiated to evaluate INCB054828 in patients with myeloid/lymphoid neoplasms with FGFR1 rearrangement (NCT03011372).

E1346

THE GRADE OF STROMAL CHANGES IMPACTS ON PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS

U. Gianelli[1,*], S. Fiori[1], D. Cattaneo[2], A. Bossi[3], I. Cortinovis[3], C. Bucelli[2], N. Orofino[2], A. Iurlo[2]
[1]Division of Pathology, IRCCS Ca' Granda - Maggiore Policlinico Hospital Foundation and University of Milan, [2]Oncohematology Division, IRCCS Ca' Granda Maggiore Policlinico Hospital Foundation, [3]Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy

Background: Recently, a detailed grading system for the assessment of bone marrow stromal changes has been proposed in primary myelofibrosis, proved to be reproducible and adopted by the updated WHO 2016 classification.
Aims: In this study, we aim to evaluate any possible prognostic implications of this grading system in a series of patients with primary myelofibrosis.
Methods: The study involved 122 consecutive patients with primary myelofibrosis diagnosed between 1998 and 2015 at the Oncohematology Division of the Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, for which an adequate bone marrow trephine biopsy (more than 1 cm in length) performed at the time of first observation was available, together with complete clinical, laboratory and follow-up data.
Results: Reticulin myelofibrosis (MF), collagen deposition (Co) and osteosclerosis (Ost) were evaluated and graded from 0 to 3 in the bone marrow trephine biopsies for each patient at diagnosis. In detail, the stromal changes were graded as follows: bone marrow fibrosis: MF-0 in 9 cases, MF-1 in 60, MF-2 in 31 and MF-3 in 22; collagen deposition: Co-0 in 64 cases, Co-1 in 23, Co-2 in 21 and Co-3 in 14; osteosclerosis: Ost-0 in 72 cases, Ost-1 in 24, Ost-2 in 19 and Ost-3 in 7. Patients' population was composed of 56 males and 66 females (M/F=1/1,2) with a median age at diagnosis of 68 years (range 30–85). Clinically, at presentation, anemia with hemoglobin values less than 10 g/dL was present in 20 (16%) patients, leukocytosis more than 25 $x10^9$/L was identifiable in 4 (3%) patients, and platelets count less than 100 $x10^9$/L in 7 (6%) cases. *JAK2*V617F mutation was detected in 81 cases (66%). Among the remaining 41 *JAK2*-negative patients, 4 and 27 carried *MPL* and *CALR* mutations, respectively; 10 out of 122 resulted "triple-negative". According to the International Prognostic Scoring System, 38 cases were stratified as low risk, 51 as intermediate-1 risk, 21 as intermediate-2 risk, and the remaining 12 as high risk. By the time of the analysis, 21 (17%) patients had died: leukemic evolution occurred in 14 (11.5%) patients, whereas thrombotic or hemorrhagic events occurred in 25 (20.5%). Subsequently, a comprehensive grade of bone marrow stromal changes ranging from 0 to 9 allows us to distinguish 88 (72%) cases with low-grade stromal changes (total score: 0-4) and 34 (28%) with high-grade stromal changes (total score: 5-9). Clinically, patients with high-grade stromal changes presented more frequently with anemia, thrombocytopenia, leukocytosis, peripheral blood blasts and increased lactate dehydrogenase levels. The grade of bone marrow stromal changes resulted strictly associated with the International Prognostic Scoring System and the overall mortality (low-grade: 10 dead out of 88 *vs* high-grade: 11 dead patients out of 34; p=0.013). Finally, the grade of bone marrow stromal changes was effective in discriminating the overall survival of the patients with low-grade and high-grade stromal changes (Log-Rank test: p=0.0002).
Summary/Conclusions: A detail evaluation of the bone marrow stromal changes has important prognostic implications and can be used at diagnosis in the clinical stratification of the patients affected by primary myelofibrosis. Further studies are needed to test if the prognostic significance of this grading system remains during the follow-up.

E1347

INCREASED RISK OF INFLAMMATORY BOWEL DISEASE IN PATIENTS WITH PHILADELPHIA NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

M. Bak[1,*], T. Jess[2], E. M. Flachs[3], A.-D. Zwisler[4], K. Juel[5], H. Frederiksen[6,7], H.C. Hasselbalch[1]
[1]Department of Haematology, Zealand University Hospital, University of Copenhagen, Roskilde, [2]Department of Clinical Epidemiology, Bispebjerg and Frederiksberg Hospital, University of Copenhagen, [3]Department of Occupational and Environmental Medicine, Bispebjerg Hospital, University of Copenhagen, Copenhagen, [4]Danish Knowledge Centre for Rehabilitation and Palliative care, University of Southern Denmark and Odense University Hospital, Odense, [5]National Institute of Public Health, University of Southern Denmark, Copenhagen, [6]Department of Haematology, Odense University Hospital, Odense, [7]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Studies reveal that patients with inflammatory bowel disease (IBD) may have increased risk of haematological cancers. Moreover, Philadelphia negative chronic myeloproliferative neoplasms (MPNs) have previously been associated with autoimmune diseases, including IBD. Nevertheless, to our knowledge, the risk of IBD has not been investigated in patients with MPN.
Aims: We undertook a nationwide population-based matched cohort study, and estimated the risk of IBD in patients with MPN.
Methods: We used valid Danish national registries, covering more than 5 million individuals, and included all patients diagnosed with either essential thrombocythemia (ET), polycythaemia vera (PV), myelofibrosis (MF), or unclassifiable myeloproliferative neoplasm (MPN-U) between 1994 and 2013. For each patient, 10 individually age- and sex-matched comparisons were included. Patients and comparisons were followed until first occurrence of any IBD diagnosis (ulcerative colitis or Crohn's disease), death, emigration or end of 2013. Patients and comparisons with prior IBD were excluded from the analysis. Hazard ratios (HRs) between MPN patients and comparisons were estimated using cox regression models, and used as measure of the relative risk. The risk was only calculated if five or more individuals were diagnosed with IBD.
Results: Of the 8,210 MPN patients, 80 individuals were diagnosed with IBD during the study period; including 37 ET patients, 28 PV patients, 1 MF patient and 14 MPN-U patients. During a total risk time of 45,241 years, the rate of IBD per 1000 person years at risk was 1.8 (95% confidence interval [95% CI]:1.4-2.2) for the MPN patients. The corresponding rate for the 81,326 comparisons was 0.8 (95% CI: 0.7-0.8).The 10-year risks of IBD for MPN patients and comparisons were 0.8% (95% CI: 0.6-1.0) and 0.4% (95% CI: 0.4-0.5), respectively. The overall HR of IBD was 2.4 (95% CI: 2.1-2.9) for MPN patients, with HRs of 2.6 (95% CI: 2.1-3.2) for ulcerative colitis and 2.4 (95% CI: 1.7-3.4) for Crohn's disease. The risk of IBD was increased 2 to 3 fold among ET, PV and MPN-U patients, with HRs of 2.8 (95% CI: 2.1-3.7) for ET patients, 2.1 (95% CI: 1.6-2.7) for PV patients and 2.2 (95% CI: 1.3-3.7) for MPN-U patients.
Summary/Conclusions: Patients with MPN are at increased risk of IBD compared to the general population. The absolute risks of IBD are low, but abdominal discomfort may in few patients be caused by underlying IBD.

E1348

ESSENTIAL THROMBOCYTHEMIA WITH AQUAGENIC PRURITUS: AN ENTITY WITH MORE AGRESSIVE CLINICAL AND BIOLOGICAL PROFILE AT THE DIAGNOSIS AND A HIGH MORBIDITY DURING THE FOLLOW-UP

C. Le Gall-Ianotto[1,2,*], R. Le Calloch[3], L.-M. Mollard[4], L. Misery[1], J.-C. Ianotto[4]
[1]Service dermatologie, CHU Brest - Hôpital Augustin Morvan, [2]laboratory of interactions epitheliums-neurones, university of Brest, Brest, [3]Service Hématologie, CHIC, Quimper, [4]Service Hématologie, CHU Brest - Hôpital Augustin Morvan, Brest, France

Background: Polycythemia vera (PV) and essential thrombocythemia (ET) are Phi-negative myeloproliferative neoplasms in which arterial or venous thromboses and phenotypical evolutions (leukemia, myelofibrosis) are the most recurrent complications. Aquagenic pruritus (AP), induced by water contact, is a typical symptom of PV. However, we showed recently that ET patients also suffered from AP with clinical characteristics quite different from those observed in PV patients. In 2008, the presence of AP was associated with a lower risk of arterial thrombosis in PV patients.
Aims: It seemed particularly interesting to analyse the clinical relevance and the prevalence of the presence of AP in ET patients for such a risk.
Methods: In this study, we used the OBENE observatory (Observatoire Brestois des NEoplasies myéloprolifératives), a register of MPN patients followed in our University Hospital in which biological and clinical data of 396 ET patients have been collected. This register was approved by a local ethical committee and registered in clinicaltrials.gov (NCT02897297). To avoid masked polycythemia Vera diagnostics, all JAK2 positive cases were tested for isotopic red mass cells if appropriate.
Results: Among our 396 ET patients, 42 (10,6%) suffered from AP. Interestingly, the median age at diagnosis of these patients was lower (51.6 *vs* 63.8%, p<0.0001). Furthermore, they presented more symptoms as erythrocytosis, hyperviscosity, constitutional symptoms and splenomegaly (p<0.01). ET patients with AP were more proliferative (more polycythemic but less thrombocythemic, p<0.04 each) and were more difficult to treat (2.2 *vs* 1.1 treatment lines, p=0.005). Concerning the occurrence of thrombotic events (arterial or venous) at diagnosis, no significant difference between patients with or without AP was found. In contrast, the presence of AP induced an increase of thrombotic events during the follow-up (30.9 *vs* 17.2%, p=0.03). But surprisingly, these events appeared in the delayed timing. The arterial/venous rate of thrombotic events was also different with 50/50 *vs* 2/3:1/3. Furthermore, we observed that about one-third of the patients with AP had phenotypic evolutions against 13.3% in the other group (p=0.0007); the most frequent evolutions were PV and secondary myelofibrosis (16.7 *vs* 5.4%, p=0.005 and 19 *vs* 4.8%, p=0.0003, respectively). Concerning the overall survival of the patients, we have noter that there was less death in the group with AP than without AP (11.9 *vs* 32.5%, p=0.006) in spite of a longest follow-up (12.1 *vs* 7.7 years, p=0.002).
Summary/Conclusions: AP is classically associated to PV. But we confirmed here that AP is also present in ET. Furthermore, ET patients suffering from AP were more proliferative, more symptomatic at diagnosis but had also higher risk of thromboses and phenotypic evolutions than ET without AP. Despite that these patients have a higher overall survival. So, the presence of AP in patients with ET characterizes patients with high risk of morbidity (thromboses, phenotypic evolutions).So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.

E1349

ANAGRELIDE RESPONSE ACCORDING TO THE MOLECULAR PROFILE: SOMETHING TO CONCLUDE ON THE MECHANISM OF ACTION OF THE DRUG IN MYELOPROLIFERATIVE NEOPLASMS (MPN)?

M. Montero[1,*], T. Knight [1], M. Domínguez[1], E. Carrillo[1], F. Márquez[1], V. Escamilla[1], P. Guerrero[1], M. Suito[1], A. Blum[1], N. Alkadi[1], J. González[1], J. Falantes[1], N. Rodríguez[1], M. Martino[1], I. Espigado[1], J. Pérez- Simón[1]
[1]Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocío, Sevilla, Spain

Background: Anagrelide is a useful drug in the control of thrombocytosis in MPN. Although it is known that in therapeutic levels it primarily influences in the post-mitotic phase of megakaryocytic development interfering with its complete maturation, its mechanism of action is not well known.
Aims: The progress in the diagnosis of MPN due to the discovery of driver mutations (JAK2, calreticulin and MPL) leads us in the present study to correlate them with the response to anagrelide in a group of patients treated with this drug, investigating the possible interference in the referred biological pathways.
Methods: a total of 56 patients with MPN diagnosed in our centre between 1993 and 2015 were studied. The median age was 49 years, with 19 patients older than 60 years. 83% were female and 17% were male. The diagnosis was initially carried out based on the WHO criteria 2008 and subsequently reviewed the medical records with the new criteria of 2016. A molecular study on peripheral blood samples was carried out using quantitative allele-specific PCR techniques for JAK2, qualitative for MPL (L515V mutation) and Sanger sequencing of exon 9 for calreticulin. Type 1 mutation was considered at 52 bp deletion and type 2 at 5 bp insertion. In all patients, the goal of anagrelide therapy was to control thrombocytosis (platelet count below 600x10e9 /L), with dosage within the range of efficacy and safety recommended in the datasheet. The results were analysed with the statistical software SPSS *vs* 15.0
Results: 80.5% of the patients were diagnosed with ET, 12.5% of PV, 3.5% of myelofibrosis and 3.5% of unclassifiable MPS. 59% of the patients had a V617F JAK2 mutation, with allelic load higher than 20% in 47.5% of the cases. 28.5% presented mutation in calreticulin; of which 50% were type 1 and 50% type 2. Only one patient had a mutation in MPL (2%), the remaining 6% being classified as “triple negative”. The median daily dose of anagrelide received was 1.5mg. 17.5% of the patients required more than 2mg for an adequate control, half of them being positive for mutations in calreticulin and the other 50% of the mutation V617F JAK2 with allelic load higher than 20%. 26% of the patients received daily dose of 1mg, being 70% positive for the mutation V617FJAK2 with allelic load lower than 20%, although there were no statistically significant differences between the groups according to the mutational profile. 16% of patients discontinued treatment due to toxicity, with the most common adverse effects being mild (headache and palpitations).
Summary/Conclusions: Patients requiring higher doses of anagrelide present mutations in calreticulin or JAK2 V617F allelic load higher than 20% and patients with lower allelic load having greater sensitivity to the drug, with no statistically significant differences. It is possible that the first situation is associated with a greater pre-mitotic deregulation in the megakaryocyte where the drug does not interfere whereas the second one could be related to anagrelide interference through the JAK2 pathway in post mitotic maturation although larger exploratory studies are required.

E1350

THE DELAYED DIAGNOSIS OF PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS (MPN) IS COMMON AND RESULTS IN A HIGH INCIDENCE OF POTENTIALLY PREVENTABLE THROMBOTIC COMPLICATIONS

C. Forsyth[1,*], C. Tiley[2], B. Wylie[2], M. Dean[2], T. Armytage[2], K. Melville[2]
[1]Medicine, Wyong Hospital, Kanwal, [2]Haematology, Gosford Hospital, Gosford, Australia

Background: Ph-negative MPNs are a heterogenous group of stem cell derived, clonal bone marrow disorders characterised by increased production of mature blood cells. Patients with MPNs are at significantly increased risk of thrombotic and haemorrhagic complications which are a major cause of morbidity and mortality. The early diagnosis and treatment of MPN may reduce the incidence of thrombotic complications and the associated morbidity and mortality.
Aims: We performed a study to determine if the delayed-diagnosis of MPN was common and the implications of any such delay.
Methods: The medical records of patients treated at our centre with a new diagnosis of MPN between January 2010 and June 2016 were audited. We determined the duration from first appearance of a full blood count (FBC) abnormality consistent with the diagnosis of MPN until the time of formal diagnosis. The occurrence of any thrombotic or haemorrhagic complications during this time was recorded.
Results: 143 patients were diagnosed with MPN; 35 with polycythemia vera, 70 with essential thrombocythemia, 25 with primary myelofibrosis and 13 with MPN-unclassifiable. Patients with PV had a median diagnosis delay of 456 days (range 0-2650 days) and 26% had potentially preventable events. Patients with ET had median diagnosis delay of 823 days (range 0-8731 days) and 23% had potentially preventable thrombotic events including 2 patients with multiple events. Patients with PMF had a median diagnosis delay of 196 days (range 0-3684 days) and 12% had potentially preventable thrombotic events. In MPN-U the median diagnosis delay was 1371 days (range 42-3255) and 31% of patients had potentially preventable adverse events.
Summary/Conclusions: Over 5.5 years we identified 143 patients with a new diagnosis of Ph-negative MPN within our centre. The overall median diagnosis delay was 723 days (0-8731) with delays of more than 12 months in ET, PV and MPN-U, and more than 6 months in PMF. 21% of patients had potentially preventable thrombotic events and 2.8% had potentially preventable haemorrhagic events. Earlier recognition of FBC abnormalities consistent with MPN should result in earlier referral for specialist haematological management which, with earlier intervention, would be expected to prevent many thrombo-haemorrhagic complications and reduce MPN-associated morbidity and mortality.

E1351

LONG-TERM AND LOW-DOSE BUSULFAN IS SAFE AND EFFECTIVE IN ELDERLY PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

R. Renso[1,*], A. Aroldi[1], P. Pioltelli[1], C. Gambacorti-Passerini[1,2,3], E. M. Elli[1]
[1]Hematology Division, [2]Clinical Research Unit, Hematology, San Gerardo Hospital, [3]Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy

Background: Therapeutic options for elderly patients (pts) with Essential Thrombocythemia (ET) resistant or intolerant to hydroxyurea (HU) are limited. Busulfan (BU) is a possible second-line treatment, but conventional schedule

(starting dose of 14mg/week up to obtain the complete hematological response CHR) is associated with high risk of leukemic transformation and second malignancies.
Aims: We analysed efficacy, toxicity, risk of Myelofibrosis (MF) and leukemic evolution in 31 of 352 ET pts collected in our database, treated with an alternative long-term schedule of BU, defined by low-starting dose (4-6mg/week) up to CHR (evaluated according to ELN response criteria), followed by dose de-escalation overtime.
Methods: Non parametric tests, such as Mann-Whitney, Pearson Chi-square and Fischer's exact tests, were used for statistical analysis of continuous and categorical variables. Survival curves were calculated by Kaplan-Meier method and compared with Log-rank (Mantel-Cox) test.
Results: 27/31 pts were evaluable for analysis (8 male, 19 female). Median age at diagnosis and at BU start were 71,3 and 79 years (yrs) respectively. We found these driver mutations: JAK2V617F in 15 pts (55.6%), Calreticulin in 8 pts (29,6%) and MPL in 1 patient (3,7%); 3 pts (11,1%) were triple negative. IPSET score at diagnosis was low-intermediate in 17 (63%) and high in 10 (37%) pts. 26 pts started BU as 2nd line treatment: 11 (42,3%) were intolerant and 15 (57,7%) were resistant to HU respectively. Only one received BU as 1st line treatment. They received BU for a median time of 47,67 months (range: 1,48 – 94,42). The median cumulative BU dose was 453mg (range: 32-1032). 25/27 pts (92,6%) obtained CHR, after a median time of 191 days. 6 pts (22,2%) presented hematological (5) and extra-hematological (1, cutaneous) side effects. Overall, 12 pts (44,4%) stopped BU: 4 for hematological toxicity, 4 for disease progression, 2 for drug intolerance/resistance; the remaining 2 not for drug-related side effects. After a median follow-up of 9,74 yrs (range: 1,82-27,05), 9 (33,3%) and 2 (7,4%) pts presented MF evolution and leukemic transformation respectively. The MF-free-survival (MFS) was 48,8% at 15 yrs and appears to be significantly lower than the entire series of ET pts (77,4% at 15 yrs; p=0,002; figure 1). Median MFS was 12,7 yrs for pts treated with BU, whereas it was not reached at 15 yrs in the entire series of ET. There were no statistically significant differences in principal hematological and clinical features between "evolving-MF pts" and "not evolving-MF pts", apart from lower hemoglobin value at BU start (11,5 *vs* 13,05 g/dl; p=0,05) and lower time of exposition to BU in MF subgroup (16 *vs* 53,7 months; p=0,026). Drug cumulative dose was the same in the two subgroups. Thrombotic complication after BU start were observed in 3 pts (11,1%). During time of analysis 5 pts (18,5%) died.

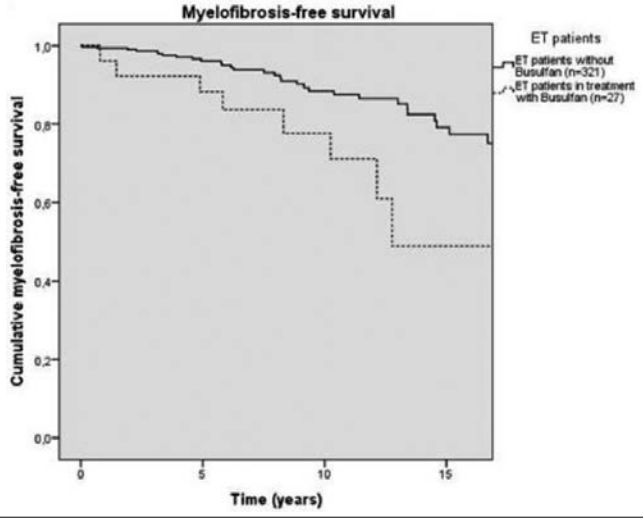

Figure 1.

Summary/Conclusions: Our experience with an alternative long-term and low-dose BU administration is safe and effective in elderly patients with ET. 92.6% of them obtained CHR, with acceptable hematological and extra-hematological toxicity. We noticed a high rate of MF evolution with respect to global ET population, while the risk of leukemic transformation seems to be limited, considering that these pts were elderly and previously treated. Predictive factors for MF evolution should be analysed and confirmed in larger series.

E1352

DIFFERENCES IN JAK2V617F POSITIVE PATIENTS WITH AND WITHOUT THROMBOSIS ACCORDING TO DIAGNOSIS, AGE, SEX AND V617F ALLELE BURDEN

I. Horvat[1,*], M. Radic Antolic[1], P. Roncevic[2], R. Serventi Seiwerth[2], R. Zadro[1]
[1]Department of Laboratory Diagnostics, [2]Department of Hematology, University Hospital Center Zagreb, Zagreb, Croatia

Background: Thrombosis is one of the most frequent events in Ph(-) myeloproliferative neoplasms and the reasons for that are still under investigation.

Aims: The aim of this study was to find out if there is difference in frequency and type of thrombosis in JAK2 V617F positive patients according to their diagnosis, age, sex and V617F allele burden.
Methods: One hundred and eighty two JAK2 V617F positive patients diagnosed with polycythemia vera (PV) N=63, essential thrombocythemia (ET) N=83, and primary myelofibrosis (PMF) N=36 were included in the study. Patients in each group were additionally divided according to sex, age at diagnosis and first thrombosis. V617F allele burden was quantified in peripheral blood granulocyte DNA by real time PCR established by Larsen *et al.* Br J Haematol 2007;136:745.
Results: Among 182 patients observed, 66 (36%) experienced thrombosis, with arterial thrombosis being twice more frequent than venous thrombosis in all 3 studied groups. In ET group there was statistically significant difference in sex distribution (proportion of females=0.71), p<0.001. Statistically significant difference in age at diagnosis was observed between ET and PV/PMF patients without thrombosis (p<0.001); the youngest patients were those in ET group. The age at diagnosis of ET patients with thrombosis (65 years, range 23-92) was statistically different compared to ET patients without thrombosis (50 years, range 21-83), p=0.002. Our study showed that V617F allele burden in patients without thrombosis was statistically significantly different between ET (17.2%, range 4.2-55.2) compared to PV (43%, range 1.7-99.9) and PMF (37.1%, range 1.4-99.7), p<0.001. The same statistically significant difference for V617 allele burden was established in patients with thrombosis between ET patients (19%, range 1.4-84.5) and PV and PMF patients (42.5%, range 8.9-97.2 and 48.8%, range 1.6-99.8, respectively), p<0.001.
Summary/Conclusions: Our results confirm that arterial thrombosis is more frequent than venous thrombosis in JAK2 V617F positive patients. Female sex was prevalent only in ET group. The age at diagnosis in all studied groups was similar except for ET patients without thrombosis. There was no difference in the frequency and type of thrombosis among ET, PV and PMF patients with high heterogeneity in V617F allele burden between all studied groups regardless of the occurrence of thrombosis.

Non-Hodgkin & Hodgkin lymphoma - Biology

PROTECTION AGAINST DEVELOPMENT OF B CELL LYMPHOMA BY TETRASPANIN CD37

C. de Winde[1], S. Veenbergen[1], K. Young[2], M. van den Brand[1], A. van der Schaaf[1], S. Elfrink[1], H. van Krieken[1], C. Figdor[1], S. van Deventer[1], B. Scheijen[1], A. Van Spriel[1,*]
[1]Radboud University Medical Center, Nijmegen, Netherlands, [2]MD Anderson Cancer Center, Houston, United States

Background: B cell non-Hodgkin lymphoma, worldwide the most common hematological malignancy, remains a clinical problem. The molecular events leading to B cell lymphoma are only partially defined. CD37 is a member of the tetraspanin superfamily that is highly expressed on mature B cells and is required for optimal GC function and long-lived antibody production.
Aims: We investigated the function of tetraspanin CD37 in the development of B cell lymphoma.
Methods: A combination of studies was performed in mouse models (CD37/IL-6-deficient mice), and studies of DLBCL patient material using biochemical, immunological, genetic and microscopical approaches.
Results: We provide evidence that deficiency of CD37 induces the development of B cell lymphoma in vivo. *Cd37*-deficient mice develop germinal center-derived B cell lymphoma in lymph nodes and spleen with higher incidence than *Bcl2*-transgenic mice. We discovered that CD37 interacts with SOCS3, and when absent drives tumor development through constitutive activation of the IL-6 signaling pathway. The importance of the IL-6 pathway was confirmed by investigating *Cd37*x*Il6* double knock-out strains that were fully protected against lymphoma development. Our unpublished data shows discovery of inactivating *CD37* mutations in patients with DLBCL. Importantly, loss of CD37 on neoplastic cells in patients with diffuse large B cell lymphoma (DLBCL) is directly correlated with activation of the IL-6 signaling pathway and with worse progression-free and overall survival.

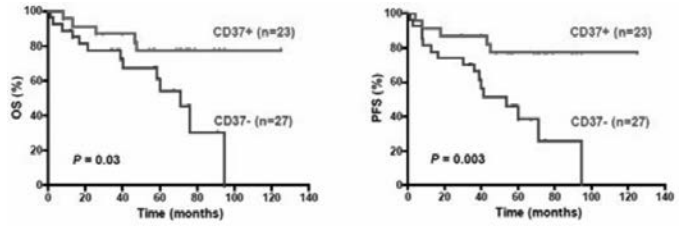

Figure 1.

Summary/Conclusions: Together, this study identifies tetraspanin CD37 as a novel tumor suppressor that directly protects against B cell lymphomagenesis, and provides a strong rationale for blocking the IL-6 pathway in patients with CD37-negative B cell malignancies as therapeutic intervention.

E1354

CONCOMITANT DUAL ABLATION OF BLIMP1 AND P53 IN B-CELLS AS A NOVEL IN VIVO MODEL FOR HIGH-GRADE B-CELL LYMPHOMA

A. Sacco[1], Y. Kawano[2], M. Moschetta[3], J. Park[3], O. Zavidij[3], D. Huynh[3], M. Reagan[4], Y. Mishima[3], E. Morgan[5], S. Takagi[3], S. Manier[3], G. Rossi[1], L. Imberti[1], K. Wong[3], R. Carrasco[3], M. Shipp[3], I. Ghobrial[3], A. Roccaro[1,*]
[1]ASST Spedali Civili di Brescia, Brescia, Italy, [2]Kumamoto University, Kumamoto, Japan, [3]Dana-Farber Cancer Institute, Boston, [4]Maine Medical Center, University of Maine, Scarborough, [5]Brigham and Women's Hospital, Boston, United States

Background: B-Lymphocyte-Induced Maturation Protein-1 (BLIMP-1)- and p53-inactivation contributes to the pathogenesis of a wide spectrum of malignancies, including diffuse large B-cell lymphomas. Nevertheless, there is lack of *in vivo* models that may be used for a better understanding of the biology and genomics of high-grade B-cell lymphomas characterized by dual loss of both BLIMP-1 and p53.
Aims: 1) To develop and characterize a transgenic mouse model of BLIMP-1/p53 dual loss in B cells; 2) To provide an *in vivo* model that mirrors human ABC-DLBCL phenotype.
Methods: Cre recombinase under the control of CD19 promoter (C57BL/6 $CD19^{Cre/Cre}$) mice were crossed with either C57BL/6 $BLIMP^{flox/flox}$or C57BL/6 $p53^{flox/flox}$mice to achieve deletion of BLIMP or p53, respectively, in B cells. Secondly, CD19Cre/Cre $BLIMP^{flox/flox}$mice were crossed with $CD19^{Cre/Cre}p53^{flox/flox}$to achieve dual deletion of BLIMP and p53 in B cells ($CD19^{Cre/Cre}BLIMP^{flox/flox}p53^{flox/flox}$: referred as CD19/Bl-/p53-). Transgenic experimental mice (CD19/Bl-/p53-) where characterized for clonal B cell infiltration using immunohistochemistry, flow cytometry, Southern Blotting, whole exome sequencing. MTT assay was used to test BTK-inhibitor-dependent cytotoxicity using CD19/Bl-/p53-derived B220 cells.
Results: CD19/Bl-/p53- mice presented with diffuse lymphadenomegalies, splenomegaly, hepatomegaly (100%, 90.3% and 77.4%, respectively). Other clinical manifestations included presence of ascites and hind lymb paralysis (12.9% and 19.3%, respectively). The CD19/Bl-/p53- showed worse survival compared to Bl-/p53- mice non-expressing the CD19/Cre recombinase, CD19/p53-, or CD19/Bl- (363, 469.5, 460.5, and 770 days, respectively). H.E. staining of CD19/Bl-/p53—derived lymph nodes, defined a nodal architecture with a monomorphic population of large sized atypical lymphoid cells, multiple basophilic medium sized, paracentrally situated nucleoli. A "starry sky" pattern was also observed. Features were compatible with a high-grade lymphomas. IHC analysis confirmed positivity for B220 staining (TdT, Bcl6, CD138 and CD4, CD8 negative). Tumors were confirmed to be B220+/IgM+, with either Igk- or Ig-lambda-restriction as demonstrated by flow cytometry; and either mono- or bi-clonal, as demonstrated by Southern blotting. Whole exome sequencing was performed from B220+ selected cells obtained from pathological lymph nodes of CD19/Bl-/p53- mice and identified 143 SNVs. Non-synonymous somatic mutations were mapped on genes involved in the regulation of focal adhesion, PDGF signaling, p53-downstream pathway, and lipoprotein metabolism. B220+ cells selected from CD19/Bl-/p53—derived lymph nodes were implanted s.q. into recipient SCID/Bg mice, and presented with 100% engraftment, with a monomorphic lymphoid infiltration of B220+ and IgM+ cells. B220 positive cells were selected from the s.q. tumor and intravenous injected into recipient SCID/Bg (n: 10) and BL/6 mice (n: 10). Engraftment was demonstrated in all the mice, where hepatomegaly, splenomegaly and hind limb paralysis were observed. Infiltration of B220+ cells was documented within bone marrow, liver and spleen. Finally, we found that B220+ cells selected from lymph nodes harvested from CD19/Bl-/p53-mice were sensitive to ibrutinib.
Summary/Conclusions: Dual inactivation of p53 and BLIMP in B-cells supports a novel *in vivo* model that recapitulates what seen in patients with ABC-DLBCL, thus providing a novel model for studying high-grade B-cell lymphoma driven by BLIMP-1/p53 dual loss-induced c-Myc expression.

E1355

IDENTIFICATION AND CHARACTERISATION OF THE LYMPHOMA INITIATING CELL (LIC) POPULATION IN AN ALCL MOUSE MODEL

S. Kreutmair[1,*], C. Klingeberg[1], G. Andrieux[2], A. Keller[1], C. Miething[1], D. Pfeifer[1], M. Follo[1], H. Busch[2], M. Boerries[2], J. Duyster[13], A.L. Illert[13]
[1]Hematology, Oncology and Stem Cell Transplantation, University medical center Freiburg, [2]Institute of Molecular Medicine and Cell Research, Freiburg, [3]German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: In 60% of anaplastic large cell lymphoma (ALCL) patients a translocation t(2;5) (p23;q35) is found, which results in NPM-ALK fusion gene expression and constitutive activation of the ALK tyrosine kinase. Immunophenotypic characterization of human ALCLs revealed highly CD30-positive cells of T- or Null-cell-origin.
Aims: However, the origin of the lymphoma initiating cell population as well as NPM-ALK signal transduction in course of the disease remains unclear and needs to be characterized.
Methods: In this regard, we established a retroviral murine bone marrow transplantation model resembling human ALCL. Therefore we use an inducible Cre/loxP system where NPM-ALK expression is restricted to early T-cells. We infected bone marrow of Lck-Cre transgenic mice with our MSCV-Stop-NPM-ALK-IRES-EGFP vector and transplanted it into lethally irradiated recipient mice. With a latency of 4-5 months, mice developed CD30-positive lymphomas and died from neoplastic T-cell infiltration of lymphatic organs and bone marrow.
Results: Immunophenotypic analysis confirmed T-cell origin of the lymphomas with a heterogeneous compound of all T-cell stages with mainly $CD4^-/CD8^-$ double negative (DN) T-cells including all DN T-cell stages as well as hematopoietic stem cells and lymphatic precursors. Staining of the T-cell subpopulations demonstrated high NPM-ALK expression in immature $CD4^-/CD8^-$ double negative T-cells and undifferentiated $CD4^+/CD8^+$ double positive T-cells with highest expression of proliferation marker Ki67 as well as the activation marker CD30 in the $CD4^-/CD8^-$ double negative T-cells. Interestingly, the $CD4^-/CD8^-$ double negative lymphoma population further more aberrantly expressed the T-cell receptor alpha/beta chain, which may allow these early T-cells to establish a systemic lymphoma. To further proof this hypothesis and identify the LIC population we performed secondary transplantations with sorted DN and T-cell subpopulations. Indeed, only mice transplanted with DN3 and DN4 lymphoma cells could give rise to secondary lymphomas, whereas sorted DN1, DN2, $CD4^+$, $CD8^+$ or $CD4^+/CD8^+$ transplanted lymphoma cells failed to established serial lymphomas in recipient mice. Immunophenotypic analyses of secondary lymphomas caused by transplantation of the DN3 and DN4 lymphoma subpopulation demonstrated double positive $CD4^+/CD8^+$ cells as well as single positive $CD4^+$ and $CD8^+$ cells next to the DN3/DN4 population. However, we were not able to detect redifferentiation of the DN3/DN4 cells to more immature DN1/DN2 lymphoma cells. To substantiate our findings, we performed microar-

ray analyses. Indeed, heatmap analyses revealed wide pattern similarities in the DN3 with DN4 lymphoma subpopulation in contrast to the DN1 and DN2 lymphoma cells. Interestingly, DN3 and DN4 cells show different expression profiles of stemness genes resembling early progenitor cell distribution patterns.
Summary/Conclusions: In summary, our results highlight the existence of a lymphoma initiating stem-cell-like population originated within the DN3/DN4 lymphoma cell population in a highly relevant NPM-ALK positive CD30-expressing ALCL mouse model, thereby giving the opportunity to test the eradication of the LIC with established and new therapeutical approaches.

E1356

HSP110 SUSTAINS MYD88-DEPENDENT NFKB SIGNALING IN ACTIVATED B CELL DIFFUSE LARGE B CELL LYMPHOMA

C. Boudesco[1], S. Causse[1], A. Hamman[2], E. Verhoeyen[3], L. Martin[1], F. Jardin[4], T. Fest[5], O. Wolz[6], A. Weber[6], C. Garrido[2], G. Jego[1,*]
[1]University of Burgundy, [2]INSERM 1231, Dijon, [3]INSERM U1111, Lyon, [4]INSERM 918, Rouen, [5]INSERM 911, Rennes, France, [6]University of Tübingen, Tübingen, Germany

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive lymphoproliferative disorder of B lymphocytes accounting for 30% of adult Non Hodgkin Lymphoma (NHL). Among DLBCL, Activated B Cell – DLBCL (ABC-DLBCL) is the most aggressive form and has a poor prognosis. Heat-shock proteins (HSPs) are molecular chaperons highly expressed in cancer cells and implicated in resistance to radio- and chemotherapy. Therefore, HSPs are envisioned as therapeutic targets in many cancers. Among the different HSPs, HSP110 has been recently identified as a pro-survival factor in germinal center-derived DLBCL (GC-DLBCL), through stabilization of the GC-DLBCL oncogene Bcl-6.
Aims: Here, we have explored if HSP110 could also be involved in the survival of the most aggressive form of DLBCL
Methods: The study was performed with ABC-DLBCL patient samples and several cell lines. ShRNA specific for HSP110 was introduced through a lentiviral vector designed to infect highly efficiently non-permissive B cell lines.
Results: We observed a high HSP110 expression in all ABC-DLBCL patient samples, compared to normal reactive lymph nodes by using IHC staining of ABC-DLBCL tumor sections and transcriptional analysis of ABC-DLBCL patient tumors. Furthermore, shRNA silencing of HSP110 decreases the survival of several ABC-DLBCL cell lines, and downregulates the expression of pro-survival factors such as BcL2 and BcL-XL. SiRNA silencing of HSP110 abrogates NF-kB signaling, which is the major oncogenic pathway in ABC-DLBCL cell lines. In accord with these results, over-expression of HSP110 in DLBCL and non-DLBCL cell lines increases NF-kB signaling, indicating a tight interplay between HSP110 and the NF-kB pathway. Using immune-precipitation in DLBCL cell lines and Duolink™ assays, we identified an *in vitro* and *in cellulo* interaction between HSP110 and Myd88, a critical protein of the NF-kB pathway that bears an activated mutation in many ABC-DLBC patients and that is responsible for lymphoma aggressiveness. Finally, we demonstrate that HSP110 stabilizes the wild type as well as the mutated form of Myd88, therefore facilitating the chronic NF-kB pathway activation in those cells.
Summary/Conclusions: In conclusion, we identified HSP110 as a regulator of NF-kB signaling through MyD88 stabilization in ABC-DLBCL. This finding highlights HSP110 as a new potential therapeutic target in DLBCL and potentially in other hematological malignancies driven by mutated MyD88 as Waldenstrom macroglobulinemia.

E1357

STAT3 ACTIVATION MEDIATES CD8+/CD16+/CD56- T-LGLL NEUTROPENIA THROUGH FAS LIGAND SECRETION

G. Barilà[1,2,*], A. Teramo[1,2], G. Calabretto[1,2], M. Leoncin[1,2], C. Vicenzetto[1,2], A. Liço[1], A. Cabrelle[2], S. Carraro[1], V. Trimarco[1], M. Facco[12], F. Piazza[1], L. Trentin[1,2], G. Semenzato[1], R. Zambello[1,2]
[1]Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, [2]Venetian Institute of Molecular Medicine, Padua, Italy

Background: T-cell large granular lymphocyte leukemia (T-LGLL) is a rare chronic lymphoproliferative disorder characterized by the clonal expansion of CD3+ Large Granular Lymphocytes (LGL). In addition to the most common CD8+ T-LGL leukemia, less frequent LGL proliferations with CD4+/CD8$^{-/+dim}$ phenotype (CD4+ T-LGL leukemia) exist, which are characterized by indolent clinical course. Somatic *STAT3* mutations determining constitutive activation have been recently reported in a proportion of approximately 40% of patients, with no clear correlation with the occurrence of neutropenia, whose pathogenesis is likely to be multifactorial, comprising both humoral (*i.e.* soluble FAS ligand secretion) and cell-mediated mechanisms.
Aims: The aim of this work was to evaluate whether 1) *STAT3* mutations might be associated with a distinctive LGL immunophenotype and/or indicative for symptomatic disease and 2) STAT3 activation is directly related to the development of neutropenia.
Methods: A cohort of 101 patients affected by T-LGLL according to WHO criteria were screened for *STAT3* mutation by Sanger sequencing and PCR ARMS assay. All the samples were analysed by flow for CD3, CD4, CD8, CD16, CD56 and CD57 antigen. STAT3 tyr 705 levels were studied by Western blot. FAS ligand mRNA levels were analysed by RT-PCR Assay.
Results: By flow we observed that 68 out of 101 patients (67.3%) were characterized by CD3+/CD8+/CD4- expression (CD8+ T-LGLL), while the remaining 33 patients (32.7%) were CD3+/CD4+/CD8+^{dim}/neg (CD4+ T-LGLL). All *STAT3* mutated (*n*=38) and almost all neutropenic (38 out of 39) patients belonged to CD8+ T-LGL leukemia (*n*=68), while among CD4+ T-LGL leukemia (*n*=33) no STAT3 mutated and only one neutropenic patient (1 out of 33, 3%) was found. Among CD8+ T-LGLL, immunophenotypic signature CD16+/CD56- was both associated to the presence of neutropenia and *STAT3* mutation (37 out of 41, 90.2%; c^2=49.5, p<0.0001 and 37 out of 41, 90.2%; c^2=49.5, p<0.0001 respectively). Furthermore, by western blot we showed that high STAT3 tyrosine phosphorylation observed in LGL obtained by CD8+ T-LGLL patients belonging to CD16+/CD56- subgroup was significantly higher as compared with other immunophenotypic groups. Provided this relationship between *STAT3* mutation/activation and neutropenia, by RT-PCR we analysed Fas ligand expression, showing higher transcription levels in CD16+/CD56- CD8+ T-LGLL patients as compared to the not neutropenic patients belonging to the other immunophenotypes, both CD8+ T-LGLL and CD4+ T-LGLL (7.66±0.87, 2.45±0.22 and 2.35±0.28 arbitrary units, respectively; p<0.01). To confirm this relationship, in patient's PMBCs treatment with *STAT3* inhibitor Stattic decreased both STAT3 phosphorylation and Fas ligand transcription as compared to the untreated conditions. In addition, IL-6 and IL-15 stimulation (which are known STAT3 activator) increased Fas ligand transcription levels (1.59- and 2.01-fold after IL-6 and IL-15, respectively) which is prevented by concomitant Stattic treatment.
Summary/Conclusions: Our results provide evidence that STAT3 mutation and activation is mostly restricted to neutropenic CD8+ T-LGLL patients equipped with the CD16+/CD56- signature. The relationship between STAT3 activation and neutropenia FAS ligand related further supports to approach STAT3 inhibition as therapeutic strategy in symptomatic CD8+/CD16+/CD56- LGLL patients, obtaining the dual results of inducing apoptosis in leukemic LGL together with inhibition to FAS ligand mediated neutropenia.

E1358

CYCLIN D2 OVEREXPRESSION RECAPITULATES MANTLE CELL LYMPHOMA IN MICE

T. Pieters[1,*], S. T'Sas[1], J. Morscio[1], F. Matthijssens[1], K. Lemeire[1], T. Hochepied[1], B. Lintermans[1], L. Reunes[1], G. Berx[1], J. Haigh[2], S. Goossens[1], P. Van Vlierberghe[1]
[1]Ghent University, Ghent, Belgium, [2]Monash University, Melbourne, Australia

Background: Mantle cell lymphoma (MCL) is a highly aggressive subtype of B-cell lymphoma that is characterized by a poor response to current treatment regimens. Most MCLs carry a prototypical translocation, t(11;14), which juxtaposes the *CCND1* gene towards the immunoglobulin heavy chain *(IGH)* locus, resulting in cyclin D1 overexpression. Notably, a subset of MCL patients are cyclin D1 negative but instead overexpress cyclin D2 (encoded by *CCND2*) as a consequence of recurrent genomic rearrangements involving the *CCND2* locus.

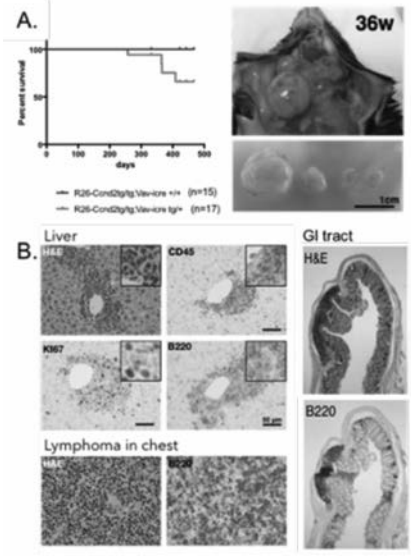

Figure 1.

Aims: Here, we aim to recapitulate MCL in a mouse model of hematopoietic-specific overexpression of cyclin D2. Next, we want to use this preclinical mouse model to evaluate novel therapeutic strategies for the treatment of MCL.
Methods: To evaluate if cyclin D2 could act as a bona fide oncogene in the pathogenesis of MCL, we developed a conditional R26-driven Ccnd2 overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the *Ccnd2* gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).
Results: The resulting R26-Ccnd2 mice were crossed to VaviCre mice to enable biallelic R26-driven overexpression of Cyclin D2 in the entire hematopoietic system. Interestingly, these mice developed large lymphomas starting from 36 weeks of age (Figure 1A), with tumor cells showing characteristic MCL immunophenotype (CD19+,CD5+,CD23-). Of note, these malignant B-cells were monomorphic small-sized cells with slightly irregular hyperchromatic nuclei and disseminated into other organs such liver, spleen and the gastrointestinal tract (Figure 1B). In addition, the infiltrating B-cell lymphoma cells were SOX11 positive, as evaluated by IHC, suggesting that these tumors indeed reflect a murine form of MCL. Noteworthy, the MCL cells from this mouse model also contain a luciferase reporter, allowing accurate *in vivo* tracing of tumor cells in xenograft experiments. These xenograft experiments can be used as preclinical models, in which bioluminescence is used to asses the tumor burden and to monitor tumor regression upon drug treatment.
Summary/Conclusions: In conclusion, our preliminary data suggest that modeling cyclin D2 in mice, mimicking the elevated cyclin D2 levels of human MCL patients with translocations involving the *CCND2* locus, is sufficient to form MCL.

E1359

HDAC6 INHIBITION INCREASES CD20 LEVEL BY STIMULATING TRANSLATION OF CD20 MRNA

A. Graczyk-Jarzynka[1,*], M. Bobrowicz[1], M. Dwojak[1], J. Stachura[1], E. Berthel[2], B. Pyrzyńska[1], M. Siernicka[1], N. Miązek[1], P. Zapała[1], N. Dalla-Venezia[2], J. Gołąb[1], M. Winiarska[1]
[1]Department of Immunology, Medical University of Warsaw, Warsaw, Poland, [2]Centre Léon Bérard – Centre de Recherche en Cancérologie de Lyon, Lyon, France

Background: HDAC6 (histone deacetylase, isoform 6) is a novel promising target in hematological malignancies. HDAC6 is an atypical member of HDAC family that regulates the acetylation status, and thus the functionality of cytosolic proteins, and has been explored therapeutically for its role in the process of protein degradation. HDAC6 mediates the transport of protein aggregates to the autophagic machinery to diminish their cytotoxicity. Thus, the disruption of the aggresome pathway, similarly to proteasome inhibition, results in a massive accumulation of misfolded protein aggregates and apoptotic cell death. As this strategy holds a considerable potential in aggressive B-cell tumors with a high rate of protein synthesis, HDAC6 inhibitors - are currently being tested in Phase I and II clinical trials in multiple myeloma and non-Hodgkin lymphoma. The results of preclinical studies show the increased efficacy of the combination of HDAC6 inhibitors with proteasome inhibitors in inducing stress-related cell death. The results of our studies show that HDAC6 inhibition in non-toxic concentrations significantly increases CD20 level on a protein level.
Aims: The aim of this study was to elucidate the mechanism of the regulation of CD20 expression by HDAC6.
Methods: We used qRT-PCR and Dual Luciferase Assays in order to determine the influence of HDAC6 on CD20 transcription. We used pulse-chase assays using widely used translation inhibitors – cycloheximide and homoharringtonine. In order to study the effect of HDAC6 inhibition on global as well as specific *de novo* synthesis of CD20 we optimized Click-IT chemistry methods. In order to study CD20 translation on polysomes we performed polysomes profiling followed with qRT-PCR. To get an insight into molecular mechanism of increased translation of CD20 after HDAC6 inhibition we studied the formation of stress granules (SG).
Results: We show that HDAC6 inhibition regulates CD20 level without affecting its transcription. Moreover, we demonstrate that HDAC6 inhibition increases translation of CD20 mRNA on polysomes without affecting general synthesis of novel proteins in the cell. However, our experiments suggest that the increased translation of CD20 mRNA is not a result of resumed translation of mRNA stalled in SG.
Summary/Conclusions: Our study shows a new mechanism of the regulation of CD20 expression by increasing its translation. Moreover, we demonstrate a new role of HDAC6 protein. This finding has a potential clinical application, as HDAC6 inhibitor are being widely tested in different hematological malignancies. Further studies in order to identify other targets for HDAC6 are required.

Background: Mantle cell lymphoma (MCL) is an incurable heterogeneous disease with a median overall survival (OS) of around 4-6 years. There are 3 prognostic groups of patients: a high-risk (HR) group of 15-20% of patients having a duration of response <1yr after end of treatment (EOT); an intermediate-risk (IG) group that includes patients remaining in response one year after EOT but with an incidence of relapse of 10-15%/yr thereafter, other patients defining the low-risk (LR) group remain in response three years at least. The MIPI score (age, leukocytosis, PS, stage) helps to classify patients according to their risk of relapse but it is not currently possible to treat patients according to risk factors. Investigation of the MCL genomic landscape could help to understand MCL biology complexity and build biology-driven medical decisions.
Aims: In the present work, we report a whole-genome copy number analysis performed with OncoScan® FFPE Assay, a new robust and validated single nucleotide polymorphism (SNP) array (Foster *et al.* BMC Med Genomics 2015). We investigated the prognostic value of somatic recurrent copy number alterations (CNA) detected in 96 young MCL patients treated in the LyMa trial (Le Gouill *et al.* Abstract 145, ASH 2016).
Methods: Samples were selected according to material availability. Lymph node biopsies collected at diagnosis, formalin-fixed and paraffin-embedded were used to extract DNA, usable even when highly degraded since the OncoScan® FFPE Assay is optimized for highly degraded FFPE samples. Whole-genome copy number profiling was analyzed with 50 ng of genomic DNA. TuScan algorithm (Affymetrix) was used to analyze data. The frequency and prognosis impact of CNAs were evaluated with univariate analysis of survival data.
Results: Characteristics of the 96 patients were as follow: median age 57y (41-65), 82% of males, MIPI-low/intermediate/high respectively 19%, 51% and 30%, blastoid morphology in 10%. No significant difference was observed between these patients and the LyMa patients (n=299). Among the 96 patients, 9 were HR patients with primary refractory disease or early relapse within one year post-diagnosis while 87 patients remained in response more than one year after diagnosis (including 64 LR patients who were still in complete remission more than 30 months after diagnosis). After ASCT, 41 patients (43%) were randomized in the rituximab maintenance arm and 40 (42%) in the observational arm. Median follow-up from diagnosis was 61.3 months (1.4-83.2). Overall, 68 recurrently altered regions were observed in 98% of patients. Deletions were more frequent than amplifications, at 9 *vs* 3 by patient respectively. HR patients were associated with *TP53*del (44%vs14%;p=.04), *CDKN2A*del (56%vs22%;p=.04), 8p11del (44%vs15%;p=.05). Interestingly, we identified in 10 patients duplication of a minimal common region of 5,3 Mb located on chromosome 7p22 and including *CARD11*. This lesion was associated with low MIPI (80%vs12%;p<.001), and other gains such as 21q21, 10q11 and 6p21 which together define a favorable subgroup (24% of the cohort). These anomalies were significantly more associated with LR patients (87%vs60%;p=.02). None of the patients with *CARD11* duplication (n=10) had relapsed despite the presence of *TP53* in 2 patients or *CDKN2A* deletion in 3 patients. This translates into a longer PFS (100%vs70%;p=.02) (fig.).

Figure 1.

Summary/Conclusions: Our study confirms the worse impact of *TP53* and *CDKN2A* deletion on early relapse in MCL. By contrast, the *CARD11* duplication

is associated with an absence of relapse and thus defines a new group of very low risk patients. These findings provide important clues for future theranostic-driven therapies in MCL.

Background: Translocation involving the *CDK6* gene is a rare but recurrent abnormality in B-cell neoplasms. Three different translocations have been described: t(2;7)(p11;q21), which is the most frequent, t(7;14)(q21;q32) and t(7;22)(q21;q11), leading to juxtaposition of *CDK6* gene with *IGK*, *IGH* or *IGL* locus respectively.
Aims: The Groupe Francophone de Cytogenetique Hematologique (GFCH) collected 35 chronic B-cell disorders with *CDK6* translocation in order to document the clinicobiological features of this uncommon aberration.
Methods: Clinical and biological data were gathered at diagnosis when available. A cytological review was performed by 3 experts in 27/35 cases. FISH was used to detect *IG* or *TRAD* and *CDK6* rearrangements, and recurrent abnormalities frequent in SMZL and CLL (trisomy 3, 12, 18, deletions of *ATM*, *TP53*, 13q14 and 7q22/7q36 loci). *TP53* (exons 4-9), *NOTCH2* (exon 34), and *IGHV* genes were analyzed by Sanger sequencing. Detection of *MYD88 L625P* was performed by real-time AS PCR.

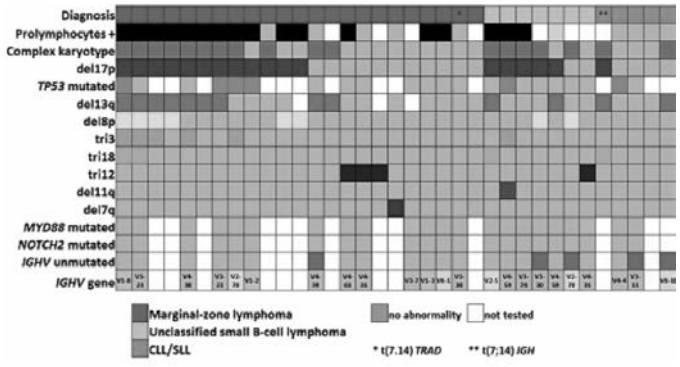

Figure 1.

Results: Our cohort included 22M and 13F, with a median age of 71 years. The involvement of *CDK6* was confirmed in all cases. A t(2;7) *IGK/CDK6* was found in 33/35 patients. One case had a t(7;14) *IGH/CDK6*, and one had a t(7;14)(q21;q11) involving the *TRAD* locus. There were 23 (66%) marginal-zone lymphoma (MZL), including 22 splenic MZL (SMZL) (including the t(7;14) *TRAD*), and 1 bronchus MALT type, 7 (20%) unclassified small B-cell lymphomas (USBCL) and 5 (14%) chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) with Matutes score 4/5 (including the t(7;14) *IGH*). Morphological review showed a contingent of prolymphocytic cells (median: 10% of lymphoid cells) in 17/27(63%) cases, including 14/19 MZL and 3/4 UBCL and 0/4 CLL/SLL. The *CDK6* translocation was the sole aberration in 9/35(26%). K was complex in 18/35(51%). The most frequent additional abnormalities were: del17p (*TP53*) (51%), del13q (41%), del8p (23%), trisomy 18 (22%), trisomy 3/3q (17%) and trisomy 12 (11%). Deletion of 7q and 11q were rare (one case of each). *TP53* was mutated in 6/22 patients (27%), including 5 with del17p. Overall, 19/29 (66%) tested cases had a *TP53* abnormality (del and/or mutated), which was significantly associated with complex karyotype (p=0.016) and del13q (p=0.042). *MYD88 L625P* was detected in 2/22 patients. No *NOTCH2* mutation was found. *IGHV* analysis showed a preferential usage of *VH4* (8/23, 35%), while *VH1* was rare (3/23, 13%, including one *VH1-2*). Most carried *IGHV* with some impact of somatic hypermutation (85%). Median follow-up was 28 months [0-192]. The median survival was not reached, only 4/32 (12.5%) died. A treatment was undertook in 15/32(47%) cases, with a median time to first treatment of 13 months. In our series, the *CDK6*+ MZL cases differed from classical SMZL by frequent prolymphocytic differentiation (14/19, 74%), very low incidence of 7q deletion (1/23, 4%), high frequency of *TP53* abnormality (12/23, 52%), absence of *NOTCH2* mutation (0/13, 0%), and a different *IGHV* repertoire with low frequency of *VH1-2* (1/13). The *CDK6*+ USBCL also had frequently a contingent of prolymphocytes (3/4, 75%), and showed a genetic profile similar to the *CDK6*+ MZL (see figure).
Summary/Conclusions: These results, obtained on the largest series to date, suggest that *CDK6* translocation is associated with indolent small B-cell lymphomas, mostly SMZL, with distinctive features. However, *CDK6* translocations can also be rarely observed in CLL/SLL. We describe one case involving the T-cell receptor (*TCR*) locus, which is a rare event in a B neoplasm. Finally, it is intriguing that this abnormality involves almost exclusively the *IGK* locus, and not the other *IG* loci, especially *IGH* which is usually the most frequently rearranged.

PRIMARY CUTANEOUS DIFFUSE LARGE B-CELL LYMPHOMA, LEG TYPE, EXPRESS STEREOTYPED B-CELL RECEPTORS WITH UNIQUE NONSYNONYMOUSLY MUTATED CONSTANT REGIONS

M.T. Koning[1,*], R. Übelhart[2], S. van der Zeeuw[3], S. Kielbasa[3], H. Jumaa[2], M. Vermeer[4], R. Willemze[4], C. Tensen[4], H. Veelken[1]

[1]Department of Hematology, Leiden University Medical Center, Leiden, Netherlands, [2]Department of Immunology, University Medical Center Ulm, Ulm, Germany, [3]Sequence Analysis Support Core, [4]Department of Dermatology, Leiden University Medical Center, Leiden, Netherlands

Background: Primary Cutaneous Diffuse Large B-Cell Lymphoma, Leg Type (DLBCL, LT) is a rare and aggressive neoplasm with a primary cutaneous presentation that shares genetic and phenotypic characteristics with DLBCL of activated B-cell subtype (ABC-DLBCL). Although receptor stereotypes have been observed, the role of the B-cell receptor (BCR) in DLBCL, LT is largely unknown. Previous studies on small cohorts suggested that DLBCL, LT expresses IgM with overrepresentation of IGHV3 alleles and high rates of somatic mutations.
Aims: We aimed to elucidate the stereotype of the BCR in DLBCL, LT and to test for autonomous antigen-independent signaling as described for CLL (Dühren-von Minden, Nature 2012) and non leg-type ABC-DLBCL (Koning, AACR 2016 & ASH 2016).
Methods: 8 cases of DLBCL, LT were subjected to RNAseq. Additional RNAseq data from 6 healthy volunteers (GEUVADIS project), 10 non leg type DLBCL, and 16 follicular lymphoma were obtained from NCBI publicly available datasets and collaborators. VDJ/VJ rearrangements and IgM constant regions were Sanger sequenced for all cases and two granulocyte controls. Lymphoma-derived, clonal BCR were tested for autonomous signalling activity in the murine TKO pre-B-cell system (Dühren-von Minden, Nature 2012).
Results: RNAseq analysis demonstrated an IgM isotype in all eight and VJ-kappa in seven DLBCL, LT cases. IGHV3 usage was observed in 7/8 cases; 4 cases expressed the IGHV3-7 gene. DLBCL, LT BCR were strongly mutated (range: VDJ 3.1-22.2%; VJ 0.6-13.5%). No intraclonal sequence variation was observed. Non-synonymous single nucleotide variants (SNV) were observed in the constant regions of four cases and in IGKC of one additional case, but not in available granulocyte DNA of two cases with C region mutations or in the other 32 RNAseq libraries. Constant region mutations were highly specific to DLBCL, LT as compared to other DLBCL (p=0.0018) and follicular lymphoma (p=0.0013). In contrast to ABC DLBCL, V(D)J BCR of DLBCL, LT on a murine constant region backbone did not induce antigen-independent calcium flux in TKO cells upon induction of functionality of the BCR signalling cascade by tamoxifen.
Summary/Conclusions: Our data identify a clearly stereotyped receptor in DLBCL, LT. In contrast to CLL and ABC-DLBCL, BCR stereotypy was not associated with autonomous BCR signalling activity using a murine IgM backbone. The pathogenic potential of the novel constant region mutations for BCR activity in DLBCL, LT warrants further functional studies.

E1363

LOSS OF NR4A1 ACCELERATES MYC-DRIVEN LYMPHOMAGENESIS ACCOMPANIED BY OVEREXPRESSION OF GENES INVOLVED IN IMMUNOREGULATION

K. Fechter[1,*], K. Wenzl[1], K. Prochazka[1], K. Pansy[1], B. Pursche[1], H. Greinix[1], C. Beham-Schmid[2], P. Neumeister[1], A. Deutsch[1]

[1]Department of Hematology/ University Clinic for Internal Medicine, Medical University of Graz, [2]Department of Hematopathology, Institute of Pathology, Medical University of Graz, Graz, Austria

Background: *NR4A1* (*Nur77*) belongs together with *NR4A2* (*Nurr1*) and *NR4A3* (*NOR-1*) to the Nur77 family of nuclear orphan receptors. As immediate early- or stress response genes their expression is diverse as it is the cellular outcome upon activation. Recently, there has been attributed a pivotal role to *NR4A1* and *NR4A3* as tumor suppressors in AML in humans and mice. In our comprehensive *NR4A* expression analysis in various lymphoma entities we demonstrated a significant reduction of *NR4A1* expression in aggressive lymphomas, which was associated with poor cancer-specific survival. Moreover, ectopic expression of *NR4A1* in aggressive lymphoma cells resulted in induction of apoptosis.
Aims: In order to better dissect the role of *Nr4a1* in lymphoid malignancies, we used a *Myc*-driven mouse model of lymphomagenesis and crossed the *EμMyc* mouse with the *Nr4a1*-/- mouse. Survival and tumor formation were monitored and RQ-PCR was performed on selected tumor specimens, whereby genes, found to be associated with *NR4A1* expression in the publicly available gene expression data set of DLBCLs generated by Lenz *et al.*, were taken. Moreover, the driver-function of *Nr4a1* in lymphomagenesis at the premalignant stage was investigated by using apoptotic assays and by carrying out transplantations of tumor cells into wt recipients.
Methods: Kaplan Meier analysis was performed for survival and tumor formation in *EμMyc Nr4a1*+/+ (n=134), *EμMyc Nr4a1*-/- (n=84) and *EμMyc Nr4a1*+/- (n=59), respectively. For RQ-PCR selected tumor specimens from wt and *EμMyc* mice with (n=14) and without (n=17) *Nr4a1* loss were used. For investigation of the role of *Nr4a1* at the premalignant stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and AnnexinV staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. *In vivo* tumor formation was induced by tumors derived from *EμMyc Nr4a1*+/+ (n=8) and *EμMyc Nr4a1*-/- (n=11) mice injected into the tail vein of wt mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACS analysis for analysis of bone marrow, spleen and tumor, respectively.
Results: *EμMyc Nr4a1*-/- mice showed decreased survival with a median of 92 days compared to *EμMyc Nr4a1* +/+ with median survival of 123 days ($p<0.001$) and tumors developed faster with a median of 45 days for *EμMyc Nr4a1*-/-, *vs* 107 days for *EμMyc Nr4a1* +/+; $p<0.001$. Both, survival (median=101 days; $p=0.037$) and tumor formation (median=66 days, $p=0.001$) gave intermediate values for *EμMyc Nr4a1* +/- mice. Furthermore, *EμMyc Nr4a1*+/+ exhibited induction of apoptosis in all investigated B cell subpopulations at the premalignant stage, whereas apoptosis was significantly diminished in *EμMyc Nr4a1*-/- mice. RQ-PCR showed that several genes involved in immunoregulation and Nf-κB target genes were upregulated in *EμMyc Nr4a1*-/- compared to *EμMyc Nr4a1*+/+. Last, tumor formation upon i.v. injection showed that tumors with *Nr4a1* loss engraft faster than tumors derived from mice without *Nr4a1* loss (25 days *vs* 38 days; $p=0.009$) and lead to a decreased number of inflammatory cells in the tumor.
Summary/Conclusions: Our results clearly demonstrate the influence of *Nr4a1* loss on tumor formation and consequently survival in a *Myc*-driven model of lymphomagenesis. Importantly, *Nr4a1* seems to impact cell death early in B cell development, even ahead of malignant transformation. Additionally, *Nr4a1* seems to be involved in driving immune responses towards an anti.-inflammatory, tolerogenic phenotype, thereby facilitating tumor growth and in altering the tumor environment. Collectively, these data underpin the tumor suppressive function of Nr4a1 in aggressive lymphomas.

DISSECTING THE PI3K PATHWAY IN A CYCLIN D1-DRIVEN MODEL OF MCL
S. Ehrenfeld[1,2,3,4,*], J. Mitschke[1], P. Veratti[1,2,3], K. Shoumariyeh[1], D. Schneider[1,2,3,4], C. Miething[1,2,3]
[1]Department of Medicine I: Hematology, Oncology, and Stem-Cell Transplantation, Medical Center, University Freiburg, [2]German Cancer Consortium (DKTK) Partnersite Freiburg, Freiburg, [3]German Cancer Research Center (DKFZ), Heidelberg, [4]Faculty of Biology, University Freiburg, Freiburg, Germany

Background: Mantle cell lymphoma (MCL) presents as a highly disseminated B-Cell malignancy, accounting for about 6% of all non-Hodgkin lymphomas. Genetically, MCL is characterized by the t(11;14)(q13;q32) translocation, leading to the overexpression of the cell cycle regulator Cyclin D1. The disease is associated with short responses to current standard therapies and a great need for new therapeutic strategies. Interestingly, the PI3K/mTOR pathway has emerged as a promising therapeutic target in MCL, as cell lines and patients have shown substantial response rates to rapamycin and analogs.
Aims: The aim of this study is to functionally dissect the role of individual PI3K/mTOR pathway genes by performing a shRNA-based screen in genetically defined primary murine MCL tumor cells. Hereby, we want to identify synthetic lethal genes for Cyclin D1 and novel molecular dependencies in Cyclin D1-driven lymphomagenesis, thereby establishing novel potential therapeutic targets in MCL.
Methods: We have developed a new mouse model for MCL using Eμ-myc transgene mice that overexpress the MCL hallmark lesion Cyclin D1, as well as the reverse tet transactivator for inducible transgene expression. Using primary MCL tumor cell lines derived from this model as a platform, we performed shRNA loss-of-function screen entailing a two colored, antibiotic selectable and tet-inducible retroviral shRNA expression vector system. A shRNA library targeting more than 300 different PI3K related genes was introduced into primary murine MCL cells. After induction of shRNA expression by addition of Dox, shRNA representation in knockdown and control cells was deconvoluted by deep sequencing to identify differentially selected shRNAs.
Results: The shRNA screen identified more than 50 strongly (> than 4 fold) differentially regulated genes affecting MCL tumor growth and survival. We identified numerous targets within the PI3K pathway and the molecular dependency on this pathway was in line with the observed high sensitivity of these cells towards pharmacological mTOR inhibition. Individual shRNA knockdown experiments confirmed the newly identified candidate genes including components of the lipid second messenger system, such as diacylglycerol kinase isoform alpha (Dgka) and gamma (Dgkg). Knockdown of these lipid kinases by three or two different hairpins lead to decreased cell proliferation. Dgka knockdown was further validated on protein level by Western Blot analysis. Furthermore, two small molecule inhibitors targeting Dgka (R59022 and Ritanserin) significantly decreased cell viability.
Summary/Conclusions: Using an unbiased shRNA screen of more than 300 genes contained in the PI3K pathway, we were able to identify a range of proteins that significantly impaired cell proliferation and cell viability in Cyclin D1-driven lymphoma cells. Among the candidate genes were components of lipid second messenger pathways, such as class I diacylglycerol kinases alpha and gamma, which could be successfully validated in downstream analyses. Dependence on these kinases was further demonstrated using two different small molecule inhibitors, indicating an important role for the diacylglycerol second messenger system in MCL growth. Their mode of action on the PI3K pathway, especially in regard to Cyclin D1, will be further investigated in murine and human MCL cells. Furthermore, additional newly identified candidate genes will be further explored to characterize their role in Cyclin D1-driven lymphomagenesis, with the aim of identifying novel therapeutic targets in this difficult-to-treat disease.

E1365

MUTATIONAL PROFILING OF HODGKIN- AND REED-STERNBERG CELLS (HRSC) OF CLASSICAL HODGKIN LYMPHOMA (CHL) ENRICHED FROM ARCHIVAL FORMALIN-FIXED AND PARAFFIN-EMBEDDED TISSUE SAMPLES
D. Juskevicius[1,*], D. Jucker[1], T. Dietsche[1], V. Perrina[1], C. Ruiz[1], S. Dirnhofer[1], A. Tzankov[1]
[1]Institute of Pathology, University Hospital Basel, Basel, Switzerland

Background: cHL can be cured in the majority of cases. However, ~10–20% patients die of the lymphoma after relapse or progressive disease. There are unmet needs for understanding the mechanisms that cause cHL relapses, for development of new prognostic/predictive markers and effective targeted therapies. Comprehensive genetic characterization and advance in understanding the molecular pathology of cHL are indispensable to meet those needs. However, genetic information on cHL is still scarce mainly due to difficulties of isolating malignant HRSC, whose overall frequencies in the affected tissues range from 0.1-5%. Formalin-fixed paraffin-embedded (FFPE) tissue archives are the most abundant source of clinically annotated tumor specimens. However, FFPE tissue usability is limited because of poor DNA quality and difficulty to enrich neoplastic cells. Therefore, new enrichment techniques are necessary to enable larger scale comprehensive genetic investigations of cHL.
Aims: Our aims were: 1) to develop a technique for HRSC enrichment from the archival formalin-fixed paraffin embedded tissue; 2) to reliably detect genetic aberrations in the genomes of enriched tumor samples and to use this information for development of new prognostic and predictive markers as well as for better understanding of the genetic background of cHL.
Methods: We have developed a new high-throughput method for marker-based enrichment of archival FFPE tissue-derived HRSC nuclei by fluorescence-assisted flow sorting (FACS). Genomic DNA extracted from sorted nuclei was used for identification of mutations in 68 genes that are frequently mutated in lymphomas by targeted high throughput sequencing (HTS). Chromosomal copy number aberrations were investigated by the Agilent SurePrint 180k microarray.
Results: Enzymatically extracted FFPE tissue-derived cell nuclei retain their antigenicity and can be reliably labelled with monoclonal antibodies against nuclear (MUM1, PAX5) and cytoplasmic/cell surface (CD30) markers. A mean neoplastic cell purity of 70% (range 40-95%) was achieved by sorting HRSC cells according to their double expression of MUM1 and CD30 in 11 cHL cases. Using sorted non-malignant cells as a germline control we detected somatic singe nucleotide mutations and indels in all investigated samples. Mutations of *STAT6*, *PIM1*, *SOCS1*, *KMT2D* occurred in at least 18% (2/11) of cases. Also, individual cases contained copy number aberrations such as gain of chr2 (*CREL* locus), focal deletions of chr4, chr7, chr16 and chr19 affecting genes such as *JAK3*, *CDKN2D*, *MAP2K3* and *NOTCH3*. Taken together our study demonstrates that DNA extracted from the enriched cell populations is suitable for wide-scale genetic profiling.
Summary/Conclusions: A novel rare-cell-enrichment technique is suitable for genetic cHL studies and opens the possibility for the wider use of archived

FFPE tissue, thus enabling more robust study designs to answer clinically relevant questions in the field.

E1366

LACK OF STAT1 PREDISPOSES TO A DIFFUSE LARGE B-CELL LYMPHOMA-LIKE DISEASE

S. Tripolt[1,*], C. Schneckenleithner[1], A. Hoelbl-Kovacic[1], G. Heller[2], V. Sexl[1]
[1]Institute of Pharmacology and Toxicology, Veterinary University of Vienna, [2]Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: The highly conserved JAK-STAT signaling pathway regulates proliferation, differentiation, apoptosis and immune responses. Activating mutations in STAT3 are considered to drive the development of diffuse large B-cell lymphomas (DLBCL). STAT1 is a critical counter player of STAT3. Of note, many STAT1 target genes are frequently altered or mutated in DLBCL patients, such as *SOCS-1*, *B2M*, *PDL1*, *CARD11, CIITA* and *BCL6*. We observed that the loss of STAT1 suffices to provoke spontaneous haematopoietic tumors in mice.
Aims: We aimed at investigating the underlying mechanisms of spontaneous hematopoietic tumor formation in STAT1-deficient mice.
Methods: We characterized the spontaneous haematopoietic tumors by FACS and morphological analysis. To identify the cell of origin for the disease, we performed bone marrow transplantation assays. We high-purity FACS-sorted individual cell populations of diseased STAT1-deficient mice and transplanted them into recipient mice. *Ex vivo* derived transformed tumor cells were characterized for lineage-specific surface marker expression and identified as B-cells. Malignant B-lymphoid STAT1-deficient cell lines were established and expression levels of typical lymphoid-specific tumor- suppressor and promoter genes were assessed by qPCR. In parallel, *Stat1*$^{-/-}$ cell lines were used for RNA-seq analysis to identify the signaling pathways driving disease. RNA-seq data were compared to publicly available RNA-seq data from different haematological malignancies.
Results: STAT1-deficient mice develop a myeloid hyperplasia that manifests with an incidence of 60% and is characterized by the absence of *Rigl*. Transplantation of bone marrow unmasked the development of a B-cell malignancy which can be transferred by CD19^{+} cells. The malignant B-cells arising in *Stat1*$^{-/-}$ mice can be maintained *in vitro* and display alterations in gene expressions that are typically found in human DLBCL such as *Irf4*, *Prdm1* and *p53.* RNA-seq analysis revealed features shared with human DLBCL: increased reads a loci of *SpiB*, *Mef2b*, *Card11* and *Cd274* (PDL1) and decreased expression of *Socs-1*, *Cdkn2a*, *B2m* and *Prdm1*. Low levels of STAT1 combined with low levels of p16^{INK4A} correlate with a reduced life expectancy in DLBCL patients.
Summary/Conclusions: Loss of STAT1 in Balb/C mice provokes a myeloid hyperplasia which masks a B-cell malignancy resembling human DLBCL. DLBCL patients with low levels of *STAT1* have a poorer prognosis if they lack the tumor suppressor p16^{INK4A}.

E1367

MOLECULAR HETEROGENEITY OF MANTLE CELL LYMPHOMA

O. Cédile[1,*], M.C. Hansen[1], L.H. Ebbesen[2], H.H.N. Bentzen[2], M. Thomassen[3], T.A. Kruse[3], M.B. Møller[4], T.K. Kristensen[4], J. Haaber[5], N. Abildgaard[5], C.G. Nyvold[1]
[1]Haematology-Pathology Research Laboratory, Department of Haematology, Odense University Hospital, Odense C, [2]Department of Haematology, Aarhus University Hospital, Aarhus C, [3]Department of Clinical Genetics, [4]Department of Pathology, [5]Department of Haematology, Odense University Hospital, Odense C, Denmark

Background: Mantle cell lymphoma (MCL) is a B-cell non-Hodgkin lymphoma characterized by t(11;14)(q13;q32) leading to constitutive cyclin D1 overexpression and cell cycle deregulation. The survival is still poor, especially for patients resistant to frontline drugs. Although patients are brought in remission, relapses often occur with disseminated lymphoma, which is more difficult to treat. There is a need for a better understanding of the clonal heterogeneity of this disease and to identify new signaling pathways with genes which could be targeted by novel drugs or be used as biomarkers to predict response to treatment.
Aims: To address the genetic heterogeneity in MCL in paired patient samples at diagnosis and relapse.
Methods: Highly pure malignant B-cell populations were isolated using fluorescence activated cell sorting in four patients diagnosed with MCL. In addition T-cells were sorted from the same patients as paired non-malignant control samples. Exome sequencing was performed on both the malignant B-cell population and paired T-cells (13 samples in total). Mutations were detected in parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) (coverage ≥ 20, population allele frequency<0.01) and evaluated against the COSMIC (Wellcome Trust Sanger Institute), dbSNP and PubMed database. Exemption from informed consent was approved by the National Ethical Committee.
Results: Our data highlighted in each patient persistent gene modifications between diagnosis and relapse. We confirmed gene mutations already well-known in B-cell malignancies (e.g. *TP53*, *NOTCH1* and *MYD88*). Interestingly, aberrations not previously described in the COSMIC database, were observed with high allele frequency both at diagnosis and at relapse. This included genes in B-cell signaling (e.g. transcriptional repressor SPEN associated to NOTCH pathway regulation and blockage of the precursor B-cell differentiation), inflammatory response (e.g. *IRG1*), genes found in invasive carcinoma (e.g. integrin β4 subunit) and B-cell malignancies (e.g. *PLA2G4D*). In addition to common mutations or hit in putative drivers, new gene modifications as well as loss of previous ones could be observed at relapse. For example, genes involved in embryonic development and cell fate (e.g. the transcription factor SOX1) and genes involved in inflammation (*CCL13*) were not previously correlated to MCL and were novel at relapse. This suggests that a modified malignant clone has evolved and progressed. No gene modification was observed to be shared by all four patients. However, aberrations in the same signaling pathways were identified across individuals. From allele frequency distributions detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two clearly separated clones were present, whereas another patient presented a diffuse clonal pattern at diagnosis and a more discrete biclonal pattern at relapse.
Summary/Conclusions: Our work shows examples of molecular progression from diagnosis to relapse in MCL and supports the heterogenic nature and genetic complexity of this disease. We confirm mutations in genes already known as involved in the malignant transformation of MCL and identify new ones involved in the B-cell signaling pathways. This adds valuable knowledge to the biological understanding of MCL which is pivotal in the era of precision medicine.

E1368

NOVEL TARGET GENES OF DEREGULATED MIRNAS IN DLBCL REVEALED BY ENDOGENOUS AGO2 PAR-CLIP

M. Fernandez-Mercado[1,2,*], E. Larrea[1], I. Ceberio[3], I. Goicoechea[1], O. Echaniz[4], J. Buratti[5], Y. Luo[5], M. Arauzo-Bravo[6,7], M. Landthaler[8,9], C. H. Lawrie[1,7,10]
[1]Oncology, Biodonostia HRI, [2]Biomedical Engineering, School of Engineering, University of Navarra, [3]Haematology and Haemotherapy, Donostia University Hospital, [4]Computational Intelligence Group, University of the Basque Country (UPV/EHU), San Sebastian, Spain, [5]Julien Buratti Bioinfo Consult, Plaisir, France, [6]Computational Biology and Systems Biomedicine, Biodonostia HRI, San Sebastian, [7]Ikerbasque, Basque Foundation for Science, Bilbao, Spain, [8]Medical Systems Biology, Max Delbrück Center for Molecular Medicine, [9]Chemistry and Biochemistry Institute, Freie Universität Berlin, Berlin, Germany, [10]Nuffield Department of Clinical Laboratory Sciences, University of Oxford, Oxford, United Kingdom

Background: Aberrant expression of microRNAs (miRNAs) is a widespread phenomenon in cancer. However, the functional significance of such deregulation is poorly understood as the target genes of miRNAs (the *targetome*) are notoriously difficult to predict computationally and moreover differ according to cellular context. An alternative approach is to directly sample the targetome using immunoprecipitation (IP) techniques such as PAR-CLIP. The drawback however of such techniques is the need for exogenously produced tagged proteins. Diffuse large B-cell lymphoma (DLCBL) is the most common form of non-Hodgkin lymphoma, typically aberrantly expressing *miRNA-155* (Lawrie, 2007). This miRNA is a well known key regulator of lymphomagenesis, needed for T and B cell function (Rodriguez, 2007; Thai, 2007; Vigorito, 2007), and its over-expression in pre-B cells or haematopoietic stem cells leads to oncogenic transformation (Costinean, 2006; O´Connell, 2008). Given their relevance, DLBCL and *miR-155* were chosen as models for the present study.
Aims: We set ourselves to adapt PAR-CLIP technique to allow non-engineered cells to be used based on IP of endogenous levels of Ago2. In addition, we also aimed at testing the minimum number of input cells needed for miRNA target identification.
Methods: Two DLBCL cell lines (ABC-type RIVA, and GC-type SUD-HL10) were transfected with lentiviral vectors that encoded *miR-155.* In parallel, we transfected these cells with an inhibitor of *miR-155* or with a scrambled sequence, as experimental controls (for reducing the number of false positives). Cells were then stably selected with puromycin, and grown in the presence of 100 uM 4SU for 18 h. Different amounts of these cells (300M, 50M and 10M) were then irradiated to cross-link the RNA to RNA-binding proteins. PAR-CLIP was then performed on cell lysates using anti-Ago2 mAbs for IP. The original protocol (Hafner, 2010) was modified to eliminate radioactive labelling. The recovered RNA was used for library building using TruSeq Small RNA Sample Kit v1 and the sequencing performed on an Illumina HiScanSQ system. After deduplication and alignment, T-to-C variants (indicative of miRNA-dependent binding sites) were identified, and PAR-CLIP clusters called using wavClusteR (Comoglio, 2015).
Results: Endogenous Ago2 IP, followed by a radioactive-free modified PAR-CLIP protocol yielded sufficient RNA for building libraries for NGS irrespectively of cell input. Samples gave an average ~9.7 x10^{6} aligned reads/library. There were an average of 7,370 PAR-CLIP clusters mapping to coding genes (range 4,675 - 11,004, correlating with the number of input cells, r=0.82). In all exper-

imental conditions we found that a number of the captured genes corresponded to experimentally validated targets of *miR-155*. Crucially, ontogeny analysis of the PAR-CLIP-captured genes demonstrated an enrichment of genes involved in haematopoietic and/or lymphomagenesis pathways.
Summary/Conclusions: To fully understand the role of a particular miRNA in a specific malignancy, it is essential to identify its target genes in a relevant cellular context. Using a haematological malignancy model of high clinical interest we have developed an optimised method for interrogating the miRNA:mRNA interface (*targetome*) within a cellular system without the need of ectopically express tagged Ago2, keeping physiological levels of the core component of the RISC complex unaffected. Moreover, our optimized protocol allowed us to reduce the number of input cells, therefore opening the exciting possibility of interrogating the targetome of patient primary samples.

DARATUMUMAB, A NOVEL HUMAN CD38 MONOCLONAL ANTIBODY FOR THE TREATMENT OF B-CELL NON-HODGKIN LYMPHOMA

A. Matas-Céspedes[1,*], A. Vidal-Crespo[1], V. Rodriguez[1], C. Rossi[2], G. Roué[1], A. López-Guillermo[3], E. Giné[3], A. Wiestner[4], C. Bezombes[2], E. Campo[5], D. Colomer[5], S. Balasubramanian[6], C. Chiu[6], P. Doshi[6], P. Pérez-Galán[1]
[1]Hematology-Oncology, IDIBAPS, Barcelona, Spain, [2]Hematology-Oncology, Centre de Recherche en Cancérologie de Toulouse (CRCT), Toulouse, France, [3]Hematology, Hospital Clínic, Barcelona, Spain, [4]Hematology, National Institutes of Health, Bethesda, MD, United States, [5]Pathology, Hospital Clínic, Barcelona, Spain, [6]R&D, Janssen, Spring House, PA, United States

Background: Daratumumab (DARA) is a first-in-class human monoclonal antibody that targets the CD38 epitope and is approved for the treatment of relapsed/refractory (R/R) multiple myeloma (MM) patients. DARA is currently being evaluated in phase II clinical trials as monotherapy in patients with R/R Mantle Cell Lymphoma (MCL), Follicular Lymphoma (FL) and Diffuse Large B-Cell Lymphoma (DLBCL). DARA induces tumor cell death through effector mediated mechanisms in MM, including Antibody-Dependent Cellular Cytotoxicity (ADCC), Complement-Dependent Cytotoxicity (CDC) (*de Weers M. J Immunol, 2011*) and Antibody-Dependent Cellular Phagocytosis (ADCP) (*Overdijk MB. MAbs, 2015*). In Chronic Lymphocytic Leukemia (CLL), DARA induces killing mainly via ADCC and ADCP (*Matas-Céspedes A. Clin Cancer Res, 2016*). Furthermore, immunomodulatory effects (*Krejcik J. Blood, 2016*) and modulation of the enzymatic activity of CD38 (*Lammerts van Bueren J. Blood, 2014*) have been described to contribute to its antitumor activity.
Aims: To evaluate the activity of DARA on MCL and FL cells as monotherapy and in combination with current therapies, both *in vitro* and *in vivo*.
Methods: ADCC, CDC and ADCP activities were assessed by calcein release or flow cytometry. Penetration of DARA was analyzed in a 3D model by Selective Plane Illumination Microscopy (SPIM). Molecules per cell were analyzed using Qifikit and flow cytometry. *In vivo* activity was assessed in prophylactic and therapeutic set ups using SCID mice subcutaneously (sc) or intravenously (iv) injected with $1x10^7$of MCL or FL cells. Mice were treated (human IgG control or DARA) with two different schedules: prophylactic (3 doses of 10mg/kg one dose per week) or therapeutic (20/10/10/10mg/kg, one dose per week). For the combination regimens in FL, sc injected SCID mice were treated following the therapeutic schedule in combination with Rituximab (20/10/10/10mg/kg, one dose per week) and/or CHOP (initial unique dose).
Results: DARA (0.0001-1µg/mL) induced ADCC in a dose-response manner on MCL (n=6) and FL (n=4) cell lines in the presence of PBMCs *in vitro*. Moreover, DARA induced significant levels of ADCP at 1µg/mL on MCL (n=6) and FL (n=4) cell lines in the presence of murine macrophages *in vitro*. However, DARA did not induce significant CDC in any of these models due to a high expression of the complement inhibitors CD46, CD55 and CD59, and insufficient number of CD38 molecules per cell. In a 3D model of FL, SPIM analysis revealed a maximum penetration of DARA at 1µg/mL after 48h of treatment.
We tested DARA activity *in vivo* in two different mouse models (sc and iv) of MCL and FL. In the prophylactic setting, DARA completely prevented the outgrowth and induced tumor regression of MCL (n=6) and FL (n=6) subcutaneous tumors. In the therapeutic setting, DARA significantly increased the overall survival (OS) of these mice and reduced organ infiltration of tumor cells both in the MCL (n=10) and in the FL (n=10) systemic xenograft models. In addition, the combination of DARA with Rituximab/CHOP regimen in FL, resulted in a synergistic reduction of tumor growth (n=7-10).
Summary/Conclusions: DARA shows encouraging cytotoxic activity in MCL and FL cells in the presence of external effectors *in vitro*. In addition, DARA exerts unique and substantial effects as single agent on MCL and FL tumor cell growth in different mouse models and contributes to potent therapeutic efficacy in combination with current approved therapies. These results warrant further studies of DARA in the clinical setting for these conditions.

E1370

ECTONUCLEOTIDASES CD39/CD73 ARE HIGHLY EXPRESSED ON ATLL CELLS AND RESPONSIBLE FOR GENERATING AMP/ADENOSINE

Y. Nagate[1,*], S. Ezoe[1], J. Fujita[1], M. Ichii[1], J. Toda[1], K. Oritani[1], Y. Kanakura[1]
[1]Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, Japan

Background: Adult T-cell leukemia/lymphoma (ATLL) is a mature T-cell neoplasm, linked to the human T-cell lymphotropic virus, HTLV-1. Patients with ATLL are often at the risk of opportunistic infections. It might be possible that this immunocompromised state could be induced by the function of ATLL cells having similar phenotypes with regulatory T cells (Tregs). However, difficulties of *in vitro* studies using primary tumor cells have hampered the progress of ATLL research, and it is still controversial whether ATLL tumor cells have the immunosuppressive characteristics.
Aims: In this study, we analyzed, the roles of molecules expressed in ATLL cells associated with immunosuppressive functions of Tregs.
Methods: The protocol of this study was approved by the Investigational Review Board of Osaka University Hospital. Peripheral blood mononuclear cells (PBMCs) were collected from 8 asymptomatic HTLV-1 carriers and 20 ATLL patients (3 with smoldering type, 5 with chronic type, and 12 with acute type) after getting informed consent. PBMCs from 3 ATLL patients were separated into $CD4^+CD7^-CADM1^+$ ATLL cells and adjacent $CD4^+$ $CD7^+CADM1^-$ normal T cells using Fluorescence-activated Cell Sorter(FACS), and total RNA sequencing experiments were conducted. And we also examined the expression patterns of CD39 and CD73 at in HTLV-1 carriers or each type of ATLL patients.
Results: We compared whole transcriptome of ATLL cells and normal $CD4^+$ cells. Bioinformative analyses showed that many genes associated with immunosuppressive functions of Tregs were elevated or downregulated in ATLL cells. Among these genes we focused on CD39, CD73 and CD26, because recently it has been reported that extracellular adenosine, which is catalyzed by CD39, expressed in human Tregs, and CD73, expressed in murine but not in human Tregs, has strong anti-inflammatory function and plays major role in Treg-mediated immunosuppression. Therefore, we investigated the expression of CD39 and CD73 in ATLL cell lines and primary tumor cells. We found that all of 4 ATLL cell lines expressed CD39, but not CD73 just as human effector Tregs. In contrast, the expression patterns of CD39 in 20 ATLL patients were various (Table) and interestingly, some ATLL tumor cells express CD73. Also in asymptomatic carriers, we could detect CD39 and/or CD73 positive on $CD7^-CADM1^+$abnormal fraction of $CD4^+$ cells. CD26, expressed in human naïve but not in effector Tregs, was negative in all cell lines and primary cells except for abnormal cells in one smoldering patient. Next, the role of CD39 and/or CD73 in ATLL cells was assessed. Extracellular ATP is converted into AMP by CD39. As expected, $CD39^+$ ATLL cells converted significantly more ATP than $CD39^-$ ATLL cells, which was comparable with normal effector Tregs. Conversely, mass spectrometry analysis of AMP/adenosine concentration indicated the activity of CD73 mediated AMP hydrolysis was very slow; less than 10% of 1mM AMP was converted to adenosine by $CD73^+$ ATL cells, indicating that the aberrant expression of CD73 could not efficiently increase adenosine synthesis.

Table 1.

	asymptomatic carriers	smoldering type	chronic type	acute/lymphoma type	total
$CD39^-CD73^-$	0	2	1	2	5
$CD39^-CD73^+$	3	0	1	0	4
$CD39^+CD73^-$	1	0	1	6	8
$CD39^+CD73^+$	4	1	2	4	11
total	8	3	5	12	28

Summary/Conclusions: In this study, we showed that about two thirds of ATLL samples were $CD39^+CD26^-$just as effector Tregs and have comparable level of ATPase activity as Tregs, which are expected to play some immunosuppressive function in ATL patients. Recently it is also reported that in exhausted $CD8^+$ T cells in cancer patients, CD39 is co-expressed with PD-1. CD39 expression in ATLL cells may also have some roles in immunosuppression and thus in the escape from anti-tumor immunity.

E1372

ACTIVATION OF SYK TYROSINE KINASE PLAYS A ROLE IN RESISTANCE AGAINST THE SELECTIVE BTK INHIBITOR ONO/GS-4059 IN DIFFUSE LARGE B CELL LYMPHOMA (DLBCL)

K. Tsukamoto[1,*], W. Harriet S.[1,2,3], J. Sandrine[1,3], M. J. Dyer[1,2,3]
[1]Cancer studies, [2]Molecular and Cell Biology, [3]The Ernest Waudby and Helen Scott Haematological Research Institute, University of Leicester, Leicester, United Kingdom

Background: The B-cell receptor (BCR) pathway is implicated in the survival

and proliferation of several B cell malignancies. BTK is a key regulator of this pathway. In a preliminary clinical study, the selective BTK inhibitor ONO/GS-4059 showed therapeutic activity in relapsed/refractory DLBCL of the Activated B-cell phenotype (ABC-DLBCL) (Walter et al Blood 127pp411-419,2016). However, median treatment duration in ABC-DLBCL was only 3 months due to progressive disease and development of resistance. Two acquired resistant mutations *BTK* C481S and *PLCγ2* R665W have been reported as dominant resistant mechanisms to BTK inhibition in CLL but resistance mechanisms in DLBCL have not been fully elucidated.

Aims: To determine resistance mechanisms in the ABC-DLBCL TMD8 cell line and determine new rational combinations to take into the clinic with ONO/GS-4059.

Methods: The BTK inhibitor-sensitive ABC-DLBC cell line TMD8 and cloned ONO/GS-4059 and Ibrutinib resistant TMD8 cell lines (TMD8RO and TMD8RI) were used for this study. TMD8RO has *PLCγ2* R665W whilst TMD8RI lacks both *BTK* C481S and *PLCγ2* R665W. Cell viability and apoptosis after compound treatment were assessed using Cell titer Glo assay and Annexin V/ PI staining. The effect of ONO/GS-4059 on intracellular signaling and expression of immunoreceptor were assessed by immunoblot and Flow cytometry. The mutational status of BTK and PLCγ2 in TMD8R was determined by Sanger sequencing.

Results: ONO/GS-4059 induced apoptosis in TMD8 at nanomolar concentration and over 72 hours induced classical apoptosis in >80% of cells. Although ONO/GS-4059 induced rapid reduction in ERK and AKT activation, activation of ERK and AKT rebounded within 24 hours in surviving cells. Interestingly, surface immunoglobulin M (sIgM) expression was increased more than three times in these cells leading to subsequent activation of SYK. The specific SYK inhibitor GS-9973 combined with ONO/GS-4059 inhibited the downstream ERK and AKT reactivation and induced synergistic apoptosis in TMD8. On the other hand, SYK hyper-activation as determined by phospholyration of SYK and its downstream target BLNK was also observed in the two BTK inhibitor resistant cell lines. Additionally, expression of CD5 and CD22, which negatively regulate BCR signalling, was decreased in these cells. The combination of ONO/GS-4059 and GS-9973 restored sensitivity to ONO/GS-4059 and induced synergistic apoptosis in both resistance cell lines.

Summary/Conclusions: These data show that SYK is highly activated through increased sIgM expression and/or downregulated CD5 and CD22 following BTK inhibitor treatment in ABC-DLBCL. These changes may contribute to not only the development but also the maintenance of resistance to BTK inhibitor. The combination of ONO/GS-4059 with SYK inhibitor is therefore a rational strategy for preventing and overcoming BTK inhibitor resistances.

E1373

STRO-001, A NOVEL ANTI-CD74 ANTIBODY DRUG CONJUGATE (ADC) FOR TREATMENT OF B-CELL NON-HODGKIN'S LYMPHOMA (NHL)

A. Yu[1], C. Abrahams[1], M. Embry[1], X. Li[1], V. DeAlmeida[1], J. Lee[1], S. Matheny[1], T. Kline[1], A. Yam[1], R. Stafford[1], T. Hallam[1], M. Lupher[1], A. Molina[1,*]
[1]Sutro Biopharma, South San Francisco, United States

Background: CD74 is a type II transmembrane glycoprotein involved in the formation and transport of MHC class II protein. CD74 is rapidly internalized and highly expressed in many B-cell malignancies with limited expression in normal tissues (Stein R. et al., CCR 2007). STRO-001 is a novel CD74-targeting ADC comprised of a p-azido-methyl-phenylalanine (pAMF)-containing anti-CD74 aglycosylated human IgG1 antibody (SP7219) conjugated to a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by Sutro's cell-free antibody production and click chemistry produced a well-defined homogeneous ADC with a drug-antibody ratio (DAR) of 2. Due to its limited cell permeability, the major catabolite released by STRO-001 has 1000X lower cell killing activity on CD74 positive and negative cells compared to a reference cytotoxic maytansine. Since conjugation sites were selected based on highest stability both i*n vitro and in vivo*, thereby limiting loss of drug moiety from STRO-001 in circulation, this novel ADC has potential for improved PK, safety and activity profiles.

Aims: The aim of this study was to investigate the therapeutic potential of STRO-001 in non-Hodgkin's lymphoma (NHL) cell lines and xenografts. A dose-escalating exploratory toxicology study was also conducted in cynomolgus monkeys.

Methods: Biotinylated SP7219 was used for immunohistochemistry (IHC). DBCO-Alexa647-conjugated SP7219 and flow cytometry were used for detection and quantitation of CD74 expression on NHL cell lines and B-cells from normal human donors. STRO-001 was used to determine the EC_{50} and percent span of killing in NHL cell lines. The anti-tumor activity of STRO-001 in SCID mice bearing NHL tumor cell xenografts was examined. STRO-001 was administered to cynomolgus monkeys in an exploratory dose-escalating study of repeat IV doses of 1, 3, 10 and 30mg/kg on days 1 and 15.

Results: Expression of CD74 in different lymphoma subtypes was evaluated by IHC on duplicate core (matched pair) biopsies. Medium to high CD74 expression in >70% of cells was observed in 86/100 diffuse large B-cell (DLBCL), 22/28 follicular lymphoma and 49/78 mantle cell lymphoma (MCL) samples. *In vitro* cytotoxicity assays show potent activity of STRO-001 in a diverse panel of B-cell tumor lines including 9 germinal center B-cell (GCB) diffuse large B-cell lymphoma (DLBCL), 3 activated B-cell (ABC) DLBCL, and 4 mantle cell lymphoma (MCL) cell lines with EC_{50} values ranging from 0.17-13 nM. STRO-001 has only modest effects on naïve B-cells, but exhibits more potent cell killing in activated human B-cells that have upregulated CD74 expression (similar CD74 expression as SU-DHL-6 cell line). CD74 cell surface expression is required for STRO-001 cytotoxic activity but expression level, as measured by antibody-binding capacity, does not correlate with *in vitro* potency (R^2=0.4154). STRO-001 exhibits dose-dependent tumor growth inhibition in rituximab-resistant SU-DHL-6 xenografts starting at 2.5mg/kg weekly x 3 doses. The standard of care combination of bendamustine/ rituximab (BR) + STRO-001 further improves tumor suppression in SU-DHL-6 xenografts compared to vehicle (p=0.002) or BR alone (p=0.02). Studies with a MCL xenograft model, Jeko-1, demonstrate potent anti-tumor activity compared to vehicle (p<0.0001) starting at a single STRO-001 dose of 3mg/kg, with a single 10mg/kg dose resulting in tumor regression for up to 64 days post treatment. STRO-001 treatment 14 days post tumor inoculation was used to evaluate disease progression in Mino, a slow growing disseminated MCL xenograft model. Vehicle-treated animals developed advanced disease with palpable tumors and distended abdomens, with median survival of 81.3 days. In contrast, Mino xenografts treated with STRO-001 at 3mg/kg or 10mg/kg exhibited improved survival, with most animals healthy and disease free at the time of sacrifice 135 days post inoculation. STRO-001 demonstrated B-cell depletion in cynomolgus monkeys, confirming the intended pharmacodynamic effect. Myelosuppression was observed at the highest dose but there was no evidence of off-target toxicity.

Table 1.

Table with SP7219 binding capacity (copy/cell) and STRO-001 cell killing EC_{50}

	Cell Line	ABC (Antibody Binding Capacity)	STRO-001 Cell Killing	
			EC_{50} (nM)	Span (%)
Activated B-cell-like Diffuse Large B-Cell Lymphoma	OCI-Ly3	77,435	0.46	96
	U2932	10,649	1.3	80
	RIVA (RI-1)	BD	3.3	77
	SU-DHL-2	BD	>100	
Germinal Center B-cell-like Diffuse Large B-Cell Lymphoma	WSU-DLCL2	51,090	0.17	97
	WSU-NHL	49,925	0.69	96
	SU-DHL-4	49,603	0.24	97
	Pfeiffer	47,123	0.54	88
	SU-DHL-6	23,235	0.56	96
	OCI-Ly1	21,529	0.69	96
	HT	20,788	0.34	68

	JeKo-1	14,754	0.41	97
	Rec-1	8,247	13	45

BD=Below detection (detection threshold = 4131)

Summary/Conclusions: STRO-001 demonstrates potent *in vitro* cytotoxicity in NHL cell lines and anti-tumor activity in NHL xenograft models, including prolonged survival in the disseminated Mino MCL model. STRO-001 depletes B cells in a dose-dependent manner. Clinical studies of this novel ADC for treatment of B-cell malignancies are under development.

E1374

DETECTING MALIGNANT B-CELLS IN CEREBROSPINAL FLUID: DOES THE IDEAL METHOD EXIST?

J. Osman[1], S. Tarfi[1], M. Armand[1], C. Houillier[2], S. Choquet[3], H. Agnelo[1], H. Strub[1], P. Bonnemye[1], K. Hoang-Xuan[2], M. Le Garff-Tavernier[1,*], M. Costopoulos[1], F. Davi[1]
[1]Biological Haematology Department, [2]Neuro-Oncology, [3]Clinical Haematology, Pitie-Salpetriere Hospital, Paris, France

Background: Leptomeningeal dissemination (LD) is a relatively rare but often fatal complication of lymphomas, confirmed by the analysis of the cerebrospinal fluid (CSF). The diagnosis is suspected in case of neurological symptoms, parenchymal brain involvement detected with neuroimaging techniques and confirmed by the analysis of the cerebrospinal fluid (CSF). Cytomorphological examination (CM) is still considered as the "gold standard" but remains insufficiently sensitive.

Aims: The aim of our study was to assess the benefit of more sensitive techniques, *i.e.* immunophenotyping by flow cytometry (FCM) and clonality by PCR, for the detection of malignant B cells in the CSF of patients with suspected leptomeningeal dissemination.

Methods: This study was conducted on 326 CSF samples (236 patients) referred to our laboratory between January 2015 and December 2016. CM, FCM and PCR results were recorded and classified as positive (+), negative (-) or suspicious. Immunophenotyping was performed on a FACSCanto II (BD Biosciences®) using an 8-colour panel. A sample was FCM+ when a cluster of at least 20 events with neoplastic features was detected. PCR-based analysis of immunoglobulin heavy (IGH) and light (IGL) chain rearrangements were per-

formed following the BIOMED-2 design and protocol. All PCR experiments were done in duplicates, and cases were considered PCR+ when both duplicates showed the same clonal pattern, ruling out false positivity (pseudoclonal pattern) often seen in paucicellular samples.
Results: We confirm that FCM and PCR are more sensitive than CM. Indeed, every CM+ cases (n= 16) was also FCM+ and/or PCR+ while 13 cases were FCM/PCR+ but CM-. A total of 269 samples showed similar results by FCM and PCR with presence (n=22) or absence (n=247) of lymphomatous cells whereas 25 samples were classified as suspicious by at least one technique. Eleven samples were FCM+ but PCR-. False negative (FN) PCR results can be explained in part by extensive somatic mutation in IGH genes, preventing optimal annealing of primers and thus blocking efficient amplification. Other targets less prone to somatic mutations, such as IGL, should therefore be evaluated. Conversely, 21 samples were PCR+ but FCM-. Absence of FCM detection might have resulted from the presence of very large lymphomatous cells outside the scope of analysis. Also, rapid cell death is an issue with FCM (prevented by the use of stabilizing reagents) whereas molecular techniques do not systematically require intact cells. Most of the difficulties encountered with both methods are due to occult blood contamination and poor cellularity, leading to low-intensity clonal signals by PCR and inconsistent cluster of events with FCM. In addition discordant results between FCM and PCR might be explained by sampling heterogeneity. Considering those limitations, it seems highly advisable to choose the best suited method for the follow-up according to the results at diagnosis.
Summary/Conclusions: Our results suggest that a multimodal investigation using FCM and PCR is necessary for improved detection of leptomeningeal dissemination in B-cell malignancies. It seems premature to make clinical decisions based on a single technology. Both methods, which suffer limitations that need to be acknowledged, are complementary and should be performed at diagnosis. Specific limitations of each of them should be taken in consideration for follow-up studies.

E1375

THE SYK INHIBITOR R406 DRAMATICALLY INCREASES THE SENSITIVITY OF GCB AND ABC DLBCL CELL LINES TO THE BCL-2 INHIBITOR VENETOCLAX

B. Sasi[1,*], S. Turkalj[1], D. Efremov[1]
[1]Molecular Hematology, International Centre for Genetic Engineering & Biotechnology, Trieste, Italy

Background: The BCL-2 inhibitor venetoclax demonstrated significant single-agent activity in recent clinical trials of relapsed/refractory chronic lymphocytic leukemia (CLL). However, results in some other B cell malignancies characterized by BCL-2 overexpression have not been equally impressive. This particularly refers to diffuse large B cell lymphoma (DLBCL), where only 18% of patients responded to treatment with venetoclax in a recent phase I clinical trial (Davids MS et al, J Clin Oncol. 2017).
Aims: Investigate whether the SYK inhibitor R406 can increase sensitivity of DLBCL cells to venetoclax.
Methods: The following cell lines were used: Ly4, Ly1, Ly7, Ly18, DHL4, Toledo and BJAB (all GCB DLBCL) and U2932, DHL2, Ly3, Ly10, HBL1 and TMD8 (all ABC DLCBL). The percentage of apoptotic cells was determined by Annexin V/PI staining and flow cytometry analysis. Expression of BCL-2 family members was determined by immunoblotting or RQ-PCR analysis.
Results: In a recent study, we showed that MCL-1 increases the resistance of anti-IgM stimulated CLL cells to venetoclax, and that SYK inhibitors can effectively overcome this resistance by blocking B cell receptor (BCR)-mediated MCL-1 upregulation (Bojarczuk K *et al.* Blood. 2016). Since constitutive activation of the BCR pathway has been described in both ABC and GCB DLBCL (Davis RE et al, Nature 2010; Chen L et al, Cancer Cell. 2013), we investigated whether treatment with the SYK inhibitor R406 can sensitize DLBCL cells to venetoclax. Single-agent venetoclax had only modest activity against most DLBCL cell lines at concentrations ranging up to 0.25 μM (Figure 1). Substantial apoptosis induction (>20%) was observed in only 2 GCB (Ly1 and Ly18) and 2 ABC (U2932 and Ly10) cell lines. R406 as single agent had almost no effect on tumor cell viability, with only one cell line showing >20% apoptosis induction (HBL1). However, addition of R406 to venetoclax resulted in a dramatic increase in the percentage of apoptotic cells in six of the investigated cell lines (Ly18, DHL4, U2932, Ly10, HBL1 and TMD8). A synergistic effect was also observed with Ly1 using a lower concentration of venetoclax, whereas no effect or only an additive effect was observed in the remaining cell lines (Ly4, Ly7, Toledo, BJAB, DHL2 and Ly3). Among these, only Toledo expressed similar levels of BCL-2 as the R406 + venetoclax sensitive cell lines, whereas the levels of BCL-2 in the other cell lines were extremely low or undetectable. To understand the mechanisms how R406 increases the sensitivity of DLBCL cells to venetoclax, we evaluated changes in the expression of MCL-1 and other antiapoptotic BCL-2 family proteins that have been associated with venetoclax resistance. Five of the seven R406 + venetoclax sensitive cell lines (Ly1, DHL4, U2932, HBL1 and TMD8) showed a 20-45% reduction in MCL-1 levels following 24 hours culture with 2μM R406, whereas no changes were observed in Ly18 and Ly10. However, a substantial reduction in A1 levels was observed in Ly18 and U2932 cells, whereas no substantial changes in A1 and BCL-xL expression were detected in any of the other investigated cell lines. Finally, we also investigated the effects of R406 on expression of HRK, which is a propapoptotic BCL-2 family member that was recently shown to be induced by SYK inhibition in a subset of GCB DLBCLs (Chen L et al, Cancer Cell. 2013). A substantial increase in HRK expression (140-640%) was observed in 5 of the 7 R406 + venetoclax sensitive cell lines (Ly1, Ly18, DHL4, U2932 and TMD8).

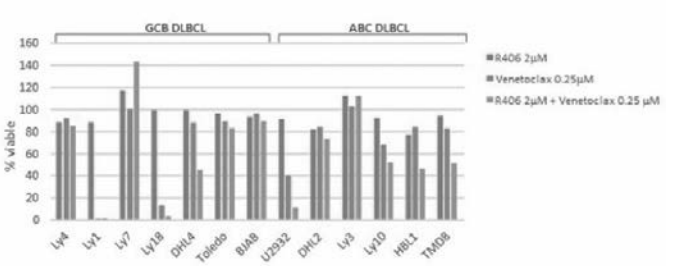

Figure 1. Viability of DLBCL cells following 24 hours *in vitro* treatment with R406, Venetoclax or both drugs combined. Values represent relative viability with respect to untreated cells.

Figure 1.

Summary/Conclusions: These data show that the SYK inhibitor R406 can significantly increase the sensitivity to venetoclax in the vast majority of BCL-2 positive DLBCL cell lines. The mechanisms of action require further investigation, but are likely to involve downregulation of MCL-1 and upregulation of HRK in a substantial proportion of cases.

E1376

VB EXPRESSION ASSESSMENT AND CLONALITY DETECTION IN T-CELL PROLYMPHOCYTIC LEUKEMIA (T-PLL) BY FLOW CYTOMETRY (FCM) AND NEXT GENERATION SEQUENCING (NGS): A COMPARISON OF BOTH METHODS

M. Kotrová[1,2,*], M. Nováková[1,2], S. Oberbeck[3], P. Mayer[3], A. Schrader[3], H. Knecht[2], M. Herling[3], M. Brüggemann[2]
[1]contributed equally, [2]Medical Department II, Unit for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, [3]Dept. of Medicine I, Cologne University, Cologne, Germany

Background: Vβ repertoire analysis can distinguish monoclonal from polyclonal (reactive) T-cell proliferations. The molecular quantification of clonal T-cell receptor (TR) gene rearrangements can also be used to record minimal residual disease (MRD) in T-cell malignancies. TR clonality can either be assessed by FCM employing Vβ antibody panels covering ~70% of the normal human TR Vβ repertoire or by molecular techniques like NGS with primers that amplify virtually all possible Vβ-Jβ rearrangements. T-PLL is the most common mature (post-thymic) T-cell leukemia. Clonal TR gene rearrangements are detected in virtually all T-PLL by FCM or PCR from peripheral blood (PB) or bone marrow samples.
Aims: To compare the results of parallel TRB-based clonality analyses by FCM and NGS in T-PLL.
Methods: We investigated diagnostic PB leukocytes of 73 T-PLL patients with median lymphocytes at 66% (range 13-93; harboring T-cells at 97% (55-100)). FCM of surface (not intracellular) Vβ expression was assessed by the IOTest Beta Mark kit (Beckman Coulter). Libraries for NGS were prepared using 100ng of DNA via a 2-step PCR and sequenced on the Illumina MiSeq (2x250bp, v2) with a median coverage of 17,908 reads (range 1,125–41,193)/sample. In the first PCR TRB rearrangements were amplified using TRB BIOMED-2 V- and J-region primers (van Dongen et al, Leukemia 2003). In the second PCR step, sequencing adaptors and sample-specific barcodes were added. Annotation of V, (D)- and J-regions of TRB sequences was done using ARResT/Interrogate (Bystry et al, Bioinformatics 2016).
Results: In all samples one or two dominant clonal TRB rearrangements were detected by NGS and represented in median by 83% of reads (range 15-90%). In 36/73 (49%) of these cases, also FCM demonstrated clonality. Interestingly, in 8/36 (22%) of cases the dominant Vβ by FCM differed from the molecular clonotype. In 5 of these cases the discrepancy was most likely accountable to a non-functional TRB clonotype detected by NGS corresponding to a bi-allelic TRB rearrangement with the second non-functional allele being preferentially identified by NGS. In 37/73 (51%) of cases no reactivity with one of the Vβ antibodies was seen. In 16 (43%) of these cases this could be attributed to expression of a TRB rearrangement for which the appropriate Vβ antibody was not present in the FCM panel. In another 12 (33%) of these cases a non-productive TRB rearrangement represented the dominant NGS clonotype. However, in further 9 cases (24%), the functional TRB clonotype (TRBV 5-6, 6-5, 25-1, 18, 20-1, 27) was not detected by FCM despite theoretical coverage. Of note, overal 10/73 T-PLL (14%) lacked surface TRα/β chain expression.
Summary/Conclusions: T-cell clonality is detected by TRB NGS in all T-PLL, whereas FCM-based Vβ repertoire analysis identifies a dominant single Vβ

domain expression in only 49%. A substantial proportion of such failures of FCM-based clonality detection can be best explained by lost surface TR expression and the limited coverage of the Vβ antibody panel. NGS-based clonality analysis can overcome these limitations, because it detects virtually all TRV VB-JB rearrangements. On the contrary, NGS is more sensitive and therefore enables the detection of minor subclones, which has great appeal for MRD analysis. Nevertheless, flow cytometric Vβ spectratyping is a faster, cheaper, and less labourious alternative. It has the additional advantage of detecting the actual TR Vβ chain expression and of visualizing individual T-cell subsets for quantification of Vβ cell populations.

IRF4 EXPRESSION IS ASSOCIATED WITH RESPONSE OF MANTLE CELL LYMPHOMA TO BRUTON'S TYROSINE KINASE INHIBITORS

H.P. Thompson[1,*], D.L. Tucker[2], S.A. Rule[1,2], C.V. Hutchinson[1,2]
[1]Institute of Translational and Stratified Medicine, Plymouth University, Peninsula Schools of Medicine and Dentistry, [2]Clinical Haematology, Plymouth Hospitals NHS Trust, Derriford Hospital, Plymouth, United Kingdom

Background: Mantle cell lymphoma (MCL) responds poorly to conventional chemotherapy. Inhibitors of Bruton's tyrosine kinase (BTKi) have unexpectedly shown significant clinical effect; however despite this success, approximately one third of MCL patients have primary resistance to the drug, and patients who initially respond to treatment frequently acquire secondary resistance and aggressive relapse of the disease. Understanding how BTKi-resistance or sensitivity is mediated can identify new targets for therapy or predictive biomarkers of response. Using an *in vitro* model system we have identified the transcription factor IRF4 as a sensitive indicator for BTKi response in MCL cell lines and primary cells.
Aims: To identify molecules or pathways responsible for resistance to BTK inhibitor-drugs in mantle cell lymphoma using cell line models and primary cells.
Methods: Primary cells and validated MCL cell lines (REC-1, G519, JEKO-1, JVM2) were cultured either alone, or together with murine stromal cells (with or without CD40L transfection). The BTKi sensitive REC-1 cell line was continuously treated with BTKi to generate an acquired resistance model. Cultures were treated with BTKi drugs: ibrutinib or acalabrutinib in the presence or absence of B-cell receptor or CD40L stimulation, and their sensitivity or resistance to treatment was determined using flow cytometry to assess proliferation (Ki67), apoptosis (Annexin-V), or phosphorylation of BTK (pY223). Changes affecting downstream proteins were determined by protein expression or phosphorylation analysis (immunoblotting) and by mRNA expression (RT PCR). Following initial experiments the studies focussed on IRF4.
Results: Each MCL cell line showed basal phosphorylation of BTK (Y223) and its downstream effector molecule ERK1/2 (Y204/187); in each case phosphorylation was prevented by BTKi. Of the cell lines tested however, only REC-1 cells showed growth inhibition by BTKi (ibrutinib and acalabrutinib), demonstrating both dose-dependent apoptosis (p=0.01) and inhibition of proliferation. Further investigation showed that only the BTKi-sensitive REC-1 cell line downregulated IRF4 in response to BTKi; this downregulation was an early and specific response (mRNA downregulated after 4 hours, and protein expression after 8 hours). Furthermore in REC-1 cells with acquired partial resistance to BTKi, the downregulation of IRF4 was significantly less than in the parental cell line. Finally *in vitro* co-culture of REC-1 cells with CD40L prevented IRF4 downregulation and protected the cells from BTKi-induced apoptosis. Experiments with primary MCL cells reinforced these findings: *in vitro* CD40L induced proliferation, survival, prevented BTKi-induced IRF4 downregulation and protected the cells from BTKi-induced death. These findings were confirmed using *ex vivo* samples from treated patients (n=7) analysed before and during BTKi treatment: IRF4 was downregulated in 6 samples from patients shown to be clinically responding to BTKi and was not downregulated in 1 refractory case.
Summary/Conclusions: CD40L encountered in the cellular microenvironment supports the proliferation and survival of MCL cells, and protects them from the effects of BTK inhibition. This study has identified that BTKi induces downregulation of IRF4 in sensitive but not resistant MCL cells, and that downregulation is opposed by CD40L. This suggests that the expression of IRF4 following treatment with BTKi might be a biomarker for BTKi-sensitivity in MCL, and that proteins modulated by IRF4 may play an important role in MCL treatment response.

E1378

LOSS OF TPL2 KINASE ACCELERATES MYC-INDUCED LYMPHOMAGENESIS

E. Stagakis[1,2,*], D. Vyrla[1], H. Papadaki[2], E. Drakos[3], A. Eliopoulos[1]
[1]Laboratory of Molecular and Cellular Biology, Medical School, University of Crete, [2]Department of Hematology, University Hospital of Heraklion, [3]Department of Pathology, Medical School, University of Crete, Heraklion, Greece

Background: While MYC t(8;14)(q24;q32) translocation was initially identified as a hallmark of Burkitt lymphoma, a number of other B-cell neoplasms are associated with MYC deregulation. These MYC-driven non-Hodgkin lymphomas have aggressive clinical behavior and respond poorly to treatment. However, MYC-dependent lymphomagenesis is believed to require additional oncogenic alterations, such as deregulation of genes that counteract the proapoptotic functions of MYC. TPL2 is a MAP3 kinase with an obligatory role in inflammatory signal transduction on the MEK/ERK axis but little is known about its involvement in B lymphocyte biology and lymphomagenesis.

Aims: The aim of this study is to define the impact of and the mechanism by which TPL2 kinase affects MYC-induced lymphomagenesis.
Methods: CD19+ positive B lymphocytes were isolated from peripheral blood of human healthy individuals and mouse B cells from spleens of WT (C57BL/6) and *Eμ-myc* transgenic mice engineered to overexpress c-*myc* in B cell progenitor cells under the control of the IgH chain enhancer. Mouse pre–B lymphocytes were isolated from bone marrow by flow cytometric cell sorting. Differentiation status of lymphomas was analysed by flow cytometry using B220, IgM and IgD antibodies. The TPL2 RNA and protein expression levels were assessed by qPCR and Western blot analysis, respectively. The extent of apoptosis was estimated by immunohistochemical evaluation of activated caspase-3 in paraffin embedded mouse lymphoma tissues and by flow cytometry using Annexin and 7AAD staining of *ex vivo* cultured lymphoma cells following cytokine deprivation.
Results: TPL2 RNA levels were found dramatically decreased in various human Burkitt lymphoma cell lines as well as in 7 primary Burkitt lymphoma biopsies compared to B lymphocytes of healthy individuals. In line with this finding, both pre-B and B lymphomas derived from *Eμ-myc* mice express very low levels of TPL2 both at RNA and protein level, compared to pre-B and splenic B lymphocytes isolated from WT mice. Interestingly, pre-B and B lymphocytes of healthy (premalignant) *Eμ-myc* mice express TPL2 in comparable levels to their WT counterparts, suggesting that the reduction of TPL2 expression in lymphomas is an additional oncogenic alteration. In this regard, genetic ablation of TPL2 in *Eμ-myc* mice (*Eμ-myc/tpl2*$^{-/-}$) significantly shortened their survival to 92 days from 140 days of Eμ-*myc/tpl2*$^{+/+}$ mice (p<0.005). Eμ-*myc/tpl2*$^{-/-}$ mice also displayed a trend to develop more pre-B cell lymphomas compared to Eμ-*myc/tpl2*$^{+/+}$ mice. This may be attributed to the decreased TPL2 expression in mouse pre-B lymphocytes, while it is upregulated in mature B lymphocytes. Finally, *Eμ-myc/tpl2*$^{-/-}$ lymphomas displayed reduced levels of apoptosis.

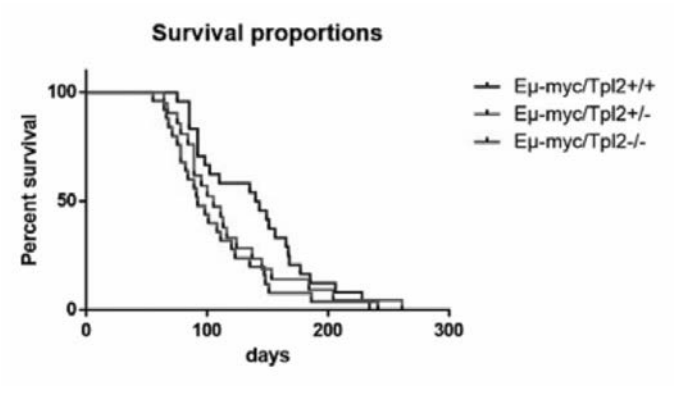

Figure 1.

Summary/Conclusions: This study reveals a novel pathway during myc-driven lymphomagenesis. We show that MYC deregulation imposes selective pressure in favor of clones with decreased expression of TPL2 kinase. This process seems to be advantageous for the malignant clone, since genetic ablation of TPL2 in the Eμ-myc mouse model accelerates MYC-induced lymphomagenesis likely by contributing to apoptosis resistance.

LIQUID BIOPSY: DECIPHERING A SIGNATURE OF CIRCULATING MICRORNAS AS NOVEL NON-INVASIVE BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA

F. Marchesi[1,*], G. Regazzo[2,3], A. Sacconi[2,3], M. Spagnuolo[2], S. Donzelli[2], F. Palombi[1], M. Marino[4], C. Ercolani[4], A. Di Benedetto[4], G. Blandino[2], A. Mengarelli[1], M.G. Rizzo[2]
[1]Hematology and Stem Cell Transplant, [2]Epigenetic and Oncogenomic Unit, Translational Research Area, [3]Regina Elena National Cancer Institute, Rome, Italy, [4]Pathology Unit, Regina Elena National Cancer Institute, Rome, Italy

Background: Up to 40% of Diffuse Large B-Cell Lymphoma (DLBCL) patients still experience treatment failure or disease relapse after conventional chemoimmunotherapy. Therefore, the search of novel non invasive biomarkers able to early identify these patients is warrant in order to offer a different therapeutic approach. Recently, bodily fluids have emerged as an important source of infor-

mation in several diseases analyzable by liquid biopsies, representing minimally invasive methods for precision diagnostics and prognosis. Blood extracellular microRNAs (miRNAs) are under investigation as novel biomarkers. While tissue miRNAs in DLBCL patients have been extensively studied, only few reports, and limited to a small subset of miRNAs, evaluated the role of circulating/serum miRNA as potential prognostic factors.
Aims: To identify and validate a serum miRNA signature with prognostic value in a cohort of newly diagnosed DLBCL patients.
Methods: This is a on-going prospective non interventionist study on a cohort of newly diagnosed *de novo* DLBCL patients uniformly treated with six courses of R-CHOP (Rituximab, Cyclophosphamide, Vincristine, Doxorubicin and Prednisone). Serum samples of patients were collected at diagnosis and after the end of treatment. Treatment response was evaluated by standard Cheson criteria. The expression profile of selected circulating miRNAs described as associated with lymphoid malignancies by us (let-7c/miR-99a/miR-125b cluster) and by previously published studies (miR-22, miR-18a and miR-20a) was evaluated by quantitative real time polymerase-chain reaction (qRT-PCR) in serum samples collected at diagnosis of the first 18 patients enrolled into the study.
Results: Our results showed that the expression level of serum miR-22 as well as let-7c/ miR-99a/125b cluster was significantly higher at diagnosis, in patients unresponsive to R-CHOP treatment when compared with responsive patients. On the contrary, miR-18 and miR-20 levels appeared to be not significantly associated to treatment response. In addition, a global expression profile of circulating miRNAs was evaluated in serum samples derived from a smaller cohort of patients (n=4) after first-line chemo-immunotherapy. Interestingly, we found a striking difference in miRNA modulation upon treatment between unresponsive and responsive patients. In particular, we found 31 miRNAs significantly modulated after R-CHOP in the group of responsive patients, including miR-22. In contrast, this miRNA subset did not show remarkable expression changes in unresponsive patients. Moreover, we performed a study interrogating The Cancer Genome Atlas (TCGA) database about miRNA expression levels in samples of DLBCL patients. We found that the only available data are relative to the miRNA expression levels in tumor tissue samples of 47 out of 58 DLBCL patients. Kaplan Meier method and log-rank test revealed a signature of 13 miRNAs with potential prognostic value. Among these we found that miR-22, also emerged as modulated in our genome-wide analysis, was linked to risk of disease recurrence.
Summary/Conclusions: These preliminary data suggest that the serum miR-22 as well as miR-99a/let-7c/miR-125b miRNA cluster are of potential interest as non–invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

E1380

INTRACELLULAR CALCIUM AND METABOLISM HAVE CRITICAL ROLES IN DETERMINING ANTI-CD20 ANTIBODY EFFICACY IN DLBCL

E. Vilventhraraja[1,*], J. Gribben[1], A. Braun[1]
[1]Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Background: Since the discovery and utilisation of the Type-I anti-CD20 antibody Rituximab, many have tried to enhance the efficacy of anti-CD20 antibodies in order to improve first-line treatment of B cell malignancies, leading to the evolution of Type II humanised anti-CD20 antibodies.To date, the complete biological role of CD20 and the mechanism of anti-CD20 antibody action remains unclear. However, CD20 has been shown to be involved in the store operated calcium (Ca2+) system. This complex has the ability to facilitate mitochondrial membrane permeabilisation, resulting in reduced mitochondrial function. Basal oxidative phosphorylation (OxPhos), ATP production, and maximal and spare respiratory capacity of cells can be calculated as a measure of mitochondrial function.
Aims: i) Assess and compare intracellular calcium concentration following treatment with anti-CD20 antibodies ii) Evaluate mitochondrial function of cells following treatment with anti-CD20 antibodies iii) Assess whether cytotoxicity of Type-I and Type-II anti-CD20 mAbs can be enhanced by exploiting cellular metabolism
Methods: We established a panel of four DLBCL cell lines (Karpas422, Pfeiffer, OCI-LY7 and SUDHL4). Following a 24-hour treatment with one of four anti-CD20 antibodies [one Type-I (Rituximab) and three Type-II anti-CD20 antibodies (BHH2, Obinotuzomab and Tositumomab)], intracellular calcium concentration was quantified and visualised using imaging flow cytometry. Next, we used the XF Seahorse Mito Stress Test to reveal bioenergetic profiles of the cell lines following a 24-hour treatment with the same antibodies. We used Metformin to inhibit oxidative phosphorylation (OxPhos) and then characterised the bioenergetic profile of our panel of cell lines again, this time to assess how combining each anti-CD20 antibody with an OxPhos inhibitor affected mitochondrial function. Metformin was also used to reduce the mitochondrial membrane potential (MMP) across our panel of cell lines. We confirmed MMP reduction by staining cells with JC-1, a chameleon dye used as an indicator of MMP and analysed samples using flow cytometry. Under the same conditions, we conducted clonogenic survival assays to see whether cytotoxicity of anti-CD20 antibodies could be enhanced by manipulating metabolism.
Results: Intracellular calcium concentration was decreased across our panel of cell lines following a 24-hour treatment with all Type-II anti-CD20 antibodies in our panel. This decrease was not observed following treatment with the Type-I anti-CD20 antibody Rituximab. Treatment with anti-CD20 antibodies resulted in a significant increase in the maximal respiratory capacity of our panel of cell lines; cells were able to produce more ATP in response to oxidative stress. Conversely, pharmacological inhibition of OxPhos impaired mitochondrial function, causing a significant reduction in basal OxPhos and in maximal respiratory capacity. Under this condition, cells were unable to increase ATP production in response to oxidative stress. We also show that treatment combining Metformin with either Type-I or Type-II anti-CD20 antibodies prevents the increase in maximal respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.
Summary/Conclusions: Our data show for the first time that when cells are treated with Type-II anti-CD20 antibodies, intracellular calcium is decreased. Intracellular calcium remains unchanged following treatment with Rituximab. Next, we show anti-CD20 antibody treatment causes cells to increase maximal mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos disables the cells from being able to compensate for the reduced mitochondrial function that is caused by CD20-antibody treatment. Importantly our data show that combining Metformin with Type-II CD20 antibodies leads to enhanced cytotoxicity, with a significant reduction in clonogenicity in our panel of DLBCL cell lines.

CYCLIN D1 ONCOGENIC OVEREXPRESSION LEADS TO A GLOBAL TRANSCRIPTIONAL DOWNREGULATION IN MALIGNANT LYMPHOID CELLS

R. Albero[1,*], A. Enjuanes[2], S. Demajo[1], G. Castellano[3], M. Pinyol[2], N. Garcia[1], C. Capdevila[1], H. Suarez-Cisneros[2], K. Karube[4], S. Bea[1], I. Martin-Subero[1], E. Campo[1], P. Jares[5]
[1]IDIBAPS, Barcelona, Spain, [2]Genomics Unit, IDIBAPS, [3]Molecular Biology Core, Hospital Clinic, Barcelona, Spain, [4]University of the Ryukyus, Okinawa, Japan, [5]Hospital Clinic, Barcelona, Spain

Background: Cyclin D1 is an oncogene frequently overexpressed in human cancers. In hematologicl neoplams, mantle cell lymphoma and multiple myeloma are clear exemples of deregulated cyclin D1 expression. It plays a dual function as cell cycle and transcriptional regulator, although the latter is widely unexplored.
Aims: In this study, we investigate the transcriptional role of cyclin D1 in lymphoid tumor cells. We aim to study initial cyclin D1 oncogenic overexpression in B cells as a model of the first steps in MCL oncogenesis.
Methods:
Chromatin immunoprecipitation (ChIP) followed sequencing was performed in four established MCL cell lines. RNA-Sequencing (RNA-Seq) and information from histone ChIP-Seq were correlated with genomic intervals displaying cyclin D1 binding. Transcriptional downregulation was studied through cytometric RNA total quantification in lymphoblastic cyclin D1-overxpressing models and RNA Pol II ChIP-Seq.
Results: Endogenous cyclin D1 showed widespread binding to active promoters and its overexpression was responsible for a global transcriptional downmodulation. Cyclin D1, instead of showing specific gene activation, seems to globally decrease cell transcription. Mantle cell lymphoma and multiple myeloma cell lines displayed an inverse relation with cyclin D1 quantity. This transcriptional effect was associated with an increased RNA polymerase II pausing in promoters due to cyclin D1 overexpression.
Summary/Conclusions: This mechanism expands the oncogenic cyclin D1 functions and places the transcriptional machinery as a potential therapeutic target in cyclin D1 overexpressing tumors.

E1382

MICROENVIRONMENTAL EXPRESSION OF IMMUNOREGULATORY MOLECULES AND CYTOKINES IN CLASSICAL HODGKIN LYMPHOMA PROGNOSIS

O. Novosad[1,*], N. Svergun[2], O. Skachkova[2], O. Gorbach[2], N. Khranovska[2], I. Kryachok[1]
[1]Oncohematology, [2]Experimental Oncology, National Cancer Institute, Kiev, Ukraine

Background: Over the past decade, new biologic insights have revealed a key role of tumor microenvironment in the pathogenesis of classical Hodgkin`s lymphoma (cHL). cHL infiltrating cells produce cytokines and growth factors that provide essential stimulatory signals for survival and proliferation of Hodgkin`s and Reed–Sternberg cells. Moreover, clinical behavior of cHL may be directly regulated by the cross-talk between tumor cells and infiltrating immune cells.

Aims: The aim of our study was to estimate the role of microenvironment expression of immunoregulatory molecules (PD-1 ligands, IDO) and cytokines (TGF-β, IL-13) in clinical outcome of cHL.
Methods: 74 patients (median age: 44, range: 17-71 years; males: 22, females: 52) were included in the study. 55.4% of patients were diagnosed with an early stages of HL, while 44.6% - with advanced stages. ABVD or BEACOPP (14/esc) were administered as a 1st-line therapy. 78.3% of patients achieved remission (CR/PR), while 8.1% had progression of disease during the therapy. We recorded 14.8% relapses in patients after the 1st line therapy during the follow-up period (median duration – 36 months; range 6–66 months). PD-L1, PD-L2, IDO, TGF-β, IL-13 mRNA expression levels were analyzed in fresh pre-treatment lymph nodes biopsies using qRT-PCR.
Results: Expression of PD-1 ligands was heterogeneous across the samples and did not depend on histological variant or stage of cHL. Only 12.1% of patients (9/74) were PD-L1 negative and all but one of those cases had a CR and a long-term remission. Patients with PD-L1 overexpression tended to have a higher rate of relapse, comparing to low/absent PD-L1 expression (p=0.1). We did not find any significant association between PD-L2 expression level and clinical outcome of cHL. Expression levels of IDO, TGF-β, IL-13 were evaluated in 38 cHL samples. 18.4% (7/38) patient were IDO positive and 81.6% (31/38) - IDO negative. The presence of IDO expression was associated with a higher risk of relapse in cHL patients (p=0.006). 85.7% (6/7) and 23.3% (7/30) of relapses were observed during the follow-up period in IDO+ and IDO- patients, respectively (p<0.05). The patients with double negative expression of PD-L1 and IDO were noted to have a favourable outcome of cHL. A 5-year event-free survival (EFS) rate was 80% for double negative PD-L1-/IDO- patients' *vs* 20% for double positive PD-L1+/IDO+ patients (p=0.008). IL-13 was expressed at various levels depending on the stage of cHL with the highest expression levels in advanced stages. A trend for a higher risk of relapse was observed for HL patients with increasing level of IL-13, (p=0.23). TGF-β expression level was not association with histological variant or stage of cHL, however multivariate analysis showed that $TGF\beta^{+}$ expression is a significant increase EFS in cHL patients with HRs of 6.7 [95% (CI) 1.3-2.1, p=0.04].
Summary/Conclusions: Our results suggest that tumor microenvironment plays an important role in clinical behavior of cHL. Hence, better understanding of molecular mechanisms of interacted between tumor and immune cells probably can provide us with a novel promising strategy for relapsed/refractory cHL treatment.

AN IN VIVO TRACEABLE AND MULTIPLEXING CRISPR/CAS9 GENOME EDITING SYSTEM

L. Cheng[1,*], T. Niu[1], Y. Liu[2]
[1]Department of Hematology and Research Laboratory of Hematology, [2]State Key Laboratory of Biotherapy and Cancer Center, West China Hospital Sichuan University, Chengdu, China

Background: Gene gain of function and loss of function mutations, oncogene overexpression, gene amplification, chromosome deletion and epigenetic changes, may lead to lymphoma onset.The CRISPR-Cas9 genome editing system has become a feasible tool for exploring the functions of specific genes in different contexts.We want to use this technique to screen for lymphoma suppressor genes.
Aims: Construct an in vivo traceable and multiplexing CRISPR-Cas9 gene editing system, which is high efficient for studying *in vivo* functions of both individual genes or any given chromosome fragment.

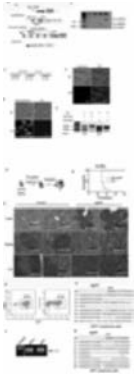

Figure 1.

Methods: Two retroviral vectors were constructed via molecular clone, one of which contains a locus for tandem U6-sgRNAs and inducible GFP reporter gene and the other contains Cas9 and tTA genes. This system's function of traceable and simultaneously mutate multiple gene efficiencies were validated in vitro. Eμ-myc HSPCs retrovirally transduced with sgp53 and Cas9 were transplanted into sublethally irradiated C57/BL6 mouse.
Results: Co-transduced cells can be tracked by the expression of GFP protein and multiple sgRNA can be efficiently introduced to the GFP-labeled cells for simultaneously mutating multiple genes or deleting a large chromosome fragment. Further we applied this system for both *in vitro* and *in vivo* genome editing. As an example, we show that *Trp53* mutation accelerated E*μ*-Myc driven lymphoma onset *in vivo.*
Summary/Conclusions: This traceable and multiplexing CRISPR/Cas9 system might be useful for various genome editing applications.

HDAC6 INHIBITION SENSITIZES TUMOR CELLS TO ANTI-CD20 IMMUNOTHERAPY *IN VIVO*

M. Bobrowicz[1,*], M. Dwojak[1], J. Stachura[1], M. Angelika[1], P. Beata[1], S. Marta[1], N. Miazek[1], P. Zapala[1], J. Golab[1], M. Winiarska[1]
[1]Department of Immunology, Medical University of Warsaw, Warsaw, Poland

Background: Down-regulation of CD20, a molecular target for monoclonal antibodies, constitutes a clinically significant issue leading to decreased efficacy of anti-CD20-based therapeutic regimens. The epigenetic modulation of CD20 coding gene (*MS4A1*) has been proposed as a mechanism for the reduced therapeutic efficacy of anti-CD20 antibodies and confirmed previously with clinically available non-specific histone deacetylase pan-inhibitors (HDACis). However, the identification of particular HDAC isoforms involved in CD20 regulation seems to be of paramount importance. Since the use of pan-HDACi is associated with substantial side effects, especially difficult to manage in elderly and frail patients, the new specific HDAC6 inhibitors are currently being tested in multiple myeloma and non-Hodgkin lymphoma. They have already been shown to sensitize tumor cells to proteasome inhibitors and novel kinase inhibitors *e.g.* ibrutinib and demonstrated promising results in *in vitro* studies in chronic lymphocytic leukemia (CLL).
Aims: HDAC6 has been known for its regulatory role in protein degradation. We have previously reported that inhibition of proteasome activity can effectively increase CD20 levels in tumor cells. In our study we tested the hypothesis that selective HDAC6 inhibition sensitizes tumor cells to immunotherapy with anti-CD20 monoclonal antibodies (mAbs) by regulating CD20 levels.
Methods: We assessed the influence of HDAC6 inhibition in a panel of different subtypes of human lymphoma cell lines (Burkitt, DLBCL; both EBV+ and EBV- cells) on CD20 expression using flow cytometry and Western blotting. We confirmed our observations in primary samples from the patients with CLL, known to express low CD20 levels. Moreover, we performed cytotoxic assays using flow cytometry in order to assess complement-dependent cytotoxicity (CDC) as well as apoptosis. We used HDAC6-specific chemical inhibitors (tubacin, trichostatin A and clinically tested ricolinostat), as well as HDAC6 shRNA assay. We also performed animal studies using SCID mice injected with Burkitt CD20+ lymphoma cell line s.c. and treated with rituximab i.p. We used both the pharmacological (i.p. administration of ricolinostat) and genetic (cells stably transduced with HDAC6 shRNA) approach.
Results: The results of our studies demonstrate that HDAC6 inhibition significantly increases CD20 level and sensitizes tumor cells to rituximab- and ofatumumab-induced CDC, as well as to direct cytotoxicity of obinutuzumab. In *in vivo* settings HDAC6 inhibition potentiated the efficacy of rituximab by significantly reducing tumor size and prolonging the survival of the mice.
Summary/Conclusions: Our results clearly indicate that HDAC6 inhibition sensitizes tumor B-cells to anti-CD20 immunotherapy. Therefore, we propose HDAC6 inhibition with specific inhibitors as an effective strategy to be associated with the therapy with anti-CD20 mAbs. This strategy seems to be highly promising in CLL patients, often expressing very low CD20 level and do not fully benefiting from immunotherapy.

Macintyre[6], V. Asnafi[6], F. Lhospice[7], C. Bonnafous[7], T. Molina[3], B. Meresse[5], C. Cellier[4], N. Cerf-Bensussan[5], O. Hermine[1,2]
[1]Hematology Unit, Necker Hospital - Paris Descartes – Sorbonne Paris Cité

University, [2]U1163, IMAGINE Institute, [3]Pathology Department, Necker Hospital - Paris Descartes – Sorbonne Paris Cité University, [4]Clinical Gastro-enterology, HEGP Hospital - Paris Descartes – Sorbonne Paris Cité University, [5]INSERM UMR1163 - Laboratory of Intestinal Immunity, IMAGINE Institute, [6]Biological Hematology, Necker Hospital - Paris Descartes – Sorbonne Paris Cité University, Paris, [7]Innate Pharma, Marseille, France

Background: Primary gastrointestinal (GI) T-cell lymphoproliferations (T-CL) are heterogeneous entities, which diagnoses are difficult to perform. T-CL include aggressive lymphoma such as enteropathy-associated T-cell lymphoma (EATL) as well as indolent monoclonal lymphoproliferations. Refractory coeliac disease type II (RCDII) is one of the indolent clonal T-CL that complicates coeliac disease (CD) and may evolve toward an overt EATL. The differential diagnosis of RCDII from CD and RCDI is difficult and essentially based on negative expression of sCD3 and CD8 and the presence of a clonal TCR rearrangement. Lymphocytes from RCDII are dependent for survival on IL-15, which reprograms T lymphocytes towards a cytotoxic NK phenotype.
Aims: We thus studied the expression of NKp46 on a representative panel of GI T-CL to assess its diagnosis and prognosis value.
Methods: Using formalin-fixed paraffin-embedded tissue biopsies, we assessed NKp46 expression by immunohistochemistry (IHC) and investigated its clinical and biologic significance on 177 intestinal, 11 lymph node and 7 other biopsies from 84 CD or RCD patients (RCDI, n=20; RCDII, n=40), 44 GI T-cell lymphoma patients (EATL, n=25; monomorphic epitheliotropic intestinal T-cell lymphoma_MEITL, n=4; indolent T-LPD, n=15), 11 healthy patients and 5 patients with a GI inflammatory environment as controls.
Results: By doing ROC analysis on number of cells expressing NKp46 on GI-TCL we identify that 25 intra-epithelial lymphocyte (IEL) per 100 epithelial cells (EC) clearly separates RCDII from CD and RCDI patients, with a good positive and negative predictive values (100 and 95% respectively). In healthy controls, CD or RCDI patients, NKp46 was only expressed on scattered IEL (median 3%, 0-15). Based on NKp46 expression the overall survival is poor if over 25% of IEL are positive for NKp46 (OS-5years 96.4% *vs* 72.8%, P=0.0004) (Figure 1A). Among patients with GI T-cell lymphoma, we show that NKp46 was expressed in most of aggressive lymphoma (EATL 80%, n=20/25 and MEITL 100%, n=4/4). On the other hand, NKp46 was never expressed on indolent T-LPD (n=0/15). The NKp46 expression was also associated with a poor prognosis in GI T-cell lymphoma patients (OS-5years 50.5% *vs* 5.4%, P=0.0011) (Figure 1B).

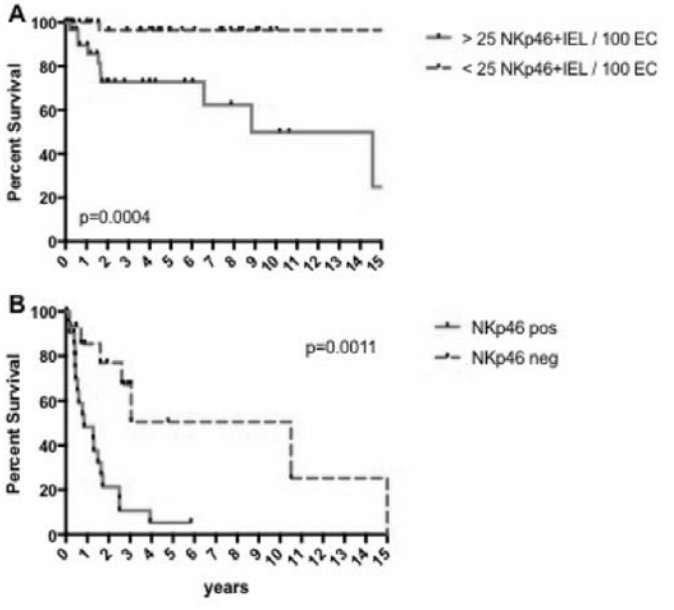

Figure 1.

Summary/Conclusions: The NKp46 expression in more than 25 IEL per 100 EC by IHC analysis can easily identify RCDII from CD and RCDI. Furthermore, the NKp46 expression is associated with aggressive forms of GI T-cell lymphoma. Finally, the NKp46 expression was strongly associated with shortened survival. Thus NKp46 provides a new biomarker for both diagnosis and prognosis in GI T-CL.

E1387

HIGH EXPRESSION LEVELS OF MIR23A CLUSTER IN DLBCL ANTAGONIZE INDUCTION OF APOPTOSIS

N. Freytag[1], C. Pommerenke[2], Y. Merkhoffer[1], J. Arribas Arranz[1], D. Kube[3], H. Drexler[2], H. Quentmeier[2], S. Eberth[1,*]

[1]Junior Research Group Molecular Cancer Research, [2]Department of Human and Animal Cell Lines, Leibniz-Institute DSMZ - German Collection of Microorganisms and Cell Cultures, Braunschweig, [3]Haematology and Oncology, University Medical Center Göttingen, Göttingen, Germany

Background: The microRNA cluster MIR23A, which encodes for the mature microRNAs miR-23a, miR-27a and miR-24, was shown to be deregulated in many different malignancies including subtypes of B cell non-Hodgkin lymphoma (B-NHL). Furthermore, high expression of miR-23a was correlated with poor overall survival in diffuse large B-cell lymphoma (DLBCL) patients (Wang *et al*., Med Oncol. 2014) indicating that miR-23a might act as an onco-miR (tumor promoting microRNA) in this entity. However, both targets and function of the MIR23A cluster in B-NHL remain unknown.
Aims: This study aims to elucidate the role of the MIR23A cluster as a potential onco-miR in DLBCL by identification of the lymphoma-specific targetomes of miR-23a and miR-27a and subsequent analyses of associated functions.
Methods: DLBCL model cell line U-2932 R1, which has a low basal expression level of MIR23A cluster, was used for the lentiviral-based generation of clones overexpressing miR-23a, miR-27a, or a scrambled control. Differentially expressed genes (DEG, fold-change >2, p-value <0.05) between samples were determined by mRNA sequencing (RNA-Seq). miR-23a and miR-27a targetomes were identified by immunoprecipitation of AGO2-bound mRNA (AGO2-RIP) followed by RNA-Seq. MicroRNA targets had to be enriched >2-fold with a p-value <0.05. Validations were performed by qPCR and immunoblotting. Gene set enrichment analyses (GSEA) and GO-term analyses were applied on identified targetomes and DEG to predict microRNA associated functions. Apoptosis was assessed by Annexin-V staining followed by FACS analyses as well as in immunoblots.
Results: Overexpression of miR-23a and miR-27a, respectively, in a DLBCL model cell line resulted in global alterations of gene expression (so-called indirect targets) with a substantial overlap of 104 of DEG affected by both microRNAs. Using AGO2-RIP, 26 novel direct targets of miR-23a, and 20 novel direct targets of miR-27a were identified. GSEA and GO-term analyses of direct and indirect targets indicated that the MIR23A cluster might regulate processes in apoptosis. Moreover, *BBC3* which encodes the pro-apoptotic protein PUMA was one of the identified direct targets of miR-27a. After etoposide induced apoptosis, miR-27a overexpressing DLBCL cells failed to induce PUMA on protein level. Importantly, functional analyses confirmed that miR-23a overexpression reduces and high levels of miR-27a significantly attenuate the ability of DLBCL cells to undergo apoptosis in response to DNA damage.
Summary/Conclusions: We demonstrate that high levels of miR-23a and miR-27a antagonize induction of apoptosis in a DLBCL model cell line. This might be one possible explanation why DLBCL patients with high miR-23a expression levels have a worse overall survival rate than patients with low levels. Thus, future studies should address the suitability of the MIR23A cluster as biomarker and potential target in DLBCL.

PLASMA CELLS ARISE FROM DIFFERENTIATION OF CLONAL LYMPHOCYTES AND SECRETE IGM IN WALDENSTRÖM MACROGLOBULINEMIA

D. Talaulikar[1,2,*], J.H. Lim[1], J. Wang[2], N. Hein[2], A. El-Ayoubi[2]
[1]Haematology, Canberra Hospital, [2]Australian National University, Australian National University, Canberra, Australia

Background: Waldenström Macroglobulinemia (WM) is an indolent non-Hodgkin lymphoma characterized by bone marrow infiltration with malignant cells and hypersecretion of monoclonal immunoglobulin M (IgM). The malignant infiltrate comprises of two distinct cellular populations: the predominant lymphoplasmacytic cells (LPLs), and a smaller number of plasma cells (PCs).
Aims: In this study, we aimed to characterise the immunophenotype, molecular genetics and secretory function of PCs in 2 WM cell lines.
Methods: Using FACS, we identified LPLs as $CD45^{bright}/CD38^{dim}/CD138^{-}/CD19^{+}/CD20^{+}$cells and PCs as $CD45^{dim}/CD38^{+}/CD138^{+}$ cells from 2 cell lines - MWCL1 (Ansell lab) and BCWM.1 (Treon lab). We used standard PCR and Sanger sequencing to assess MYD88 (using MYD88 L265P specific primers) and Immunoglobulin heavy chain (IgHV) (using Biomed2 specific primers for FR3) status. Finally to determine which population was predominantly responsible for IgM hypersecretion, isolated PCs and LPLs from both cell lines were kept in culture for 72 hours and the culture media analysed by ELISA for IgM secretion.
Results: Using a conservative sorting strategy, we analysed 2 WM cell lines MWCL1 and BCWM.1, and found that MWCL1 had 5~6% PCs and 20-30% LPLs; while BCWM.1 had 4-5% PCs and 10-20% LPLs. Cells that were $CD38^{+}/CD138^{-}$ or $CD38^{-}/CD138^{+}$ were not included. Both cell lines expressed heterozygous MYD88-L265P mutation in both PC and LPL populations. We also observed the expression of the same auto-reactive IgHV sequences (VH3-15*01) in both PCs and LPLs from MWCL-1, suggesting similar clonal origin and a role for auto-antigens in WM cell survival. We noted VH3-23*01 in the LPL population of BCWM.1 but not in the PC compartment – the significance of this remains uncertain. Cell culture studies showed that PCs alone were primarily responsible for IgM production despite the relative lack of proliferation and eventual cell death in MWCL-1 (~65% plasma cells remained after 72

hours and produced 8.7 ~ 9.3 X 10^3 ng/ml of IgM). PCs isolated from BCWM.1 increased to 130% and produced 2.5 ~2.8 X 10^3 ng/ml of IgM. LPLs from both cell lines proliferated in culture (~ 130 ~ 140% in MWCL-1 and ~170 ~ 200% in BCWM.1 at 72 hours), gave rise to the more differentiated PCs (7.5 ~ 9.0% PCs at 72 hours in MWCL-1 and 1.2 ~ 1.4% PCs in BCWM.1), and secreted smaller amounts of IgM than PCs (3.5 ~ 5.0 X 10^3 ng/ml in MWCL-1 and 0.3 ~ 0.7 X10^3 ng/ml in BCWM.1.

Summary/Conclusions: Our analysis of the 2 WM cell lines provides evidence to support the common hypothesis that malignant PCs arise from the clonal malignant LPL population, and are primarily responsible for IgM secretion in WM.

E1389

LMP-1 MEDIATED UPREGULATION OF IL-2RA PROMOTES LYMPHOMAGENESIS AND CHEMOTHERAPY RESISTANCE IN NATURAL KILLER/T-CELL LYMPHOMA AND COULD BE A POTENTIAL THERAPY TARGET

X.-W. Bi[1], W.-J. Liu[2], Z.-J. Xia[2], W.-Q. Jiang[1], H.-Q. Huang[1], Y. Lu[2], L. Wang[2,*]
[1]medical oncology, [2]Hematologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Natural killer/T-cell lymphoma (NKTCL) is an Epstein–Barr virus (EBV)-associated, highly aggressive lymphoma. Treatment outcome remains sub-optimal, especially for advanced-stage or relapsed diseases. Our previous study demonstrated the prognostic value of IL-2Rα in NKTCL, but the role of IL-2Rα in the lymphomagenesis and chemotherapy resistance and its interactions with EBV in NKTCL remain to be investigated.
Aims: This study investigated the mechanism of IL-2Rα expression in NKTCL, and explored the role of IL-2Rα in lymphomagenesis and chemotherapy resistance as well as the potential role of anti-IL-2Rα treatment in NKTCL.
Methods: Expression of IL-2Rα was measured in NK-92 (LMP-1 weak expression) and SNK-6 (LMP-1 strong expression) cells by western blot, quantitative real-time PCR, enzyme-linked immunosorbent assay, and flow cytometry, respectively. LMP1-harboring lentiviral vectors were transfected into NK-92 cells to examine the correlation between LMP1 and IL-2Rα expression. Proteins in the downstream pathways of LMP1 signaling were measured in NK-92 cells transfected with LMP1-harboring or negative control vectors as well as in SNK-6 cells. Then IL-2Rα-harboring lentiviral vectors were transfected into both NK-92 cells and SNK-6 cells to examine the cell proliferation by CCK8, apoptosis by staining with Annexin V and detected by flow cytometry (FCM), cell cycle distribution by FCM analysis, and IC50 values exposed to three chemotherapy drugs (adriamycin, gemcitabine, and asparaginase) by MTT. Finally anti-IL-2Rα antibody was added to investigate its ability of reversal of drug resistance.

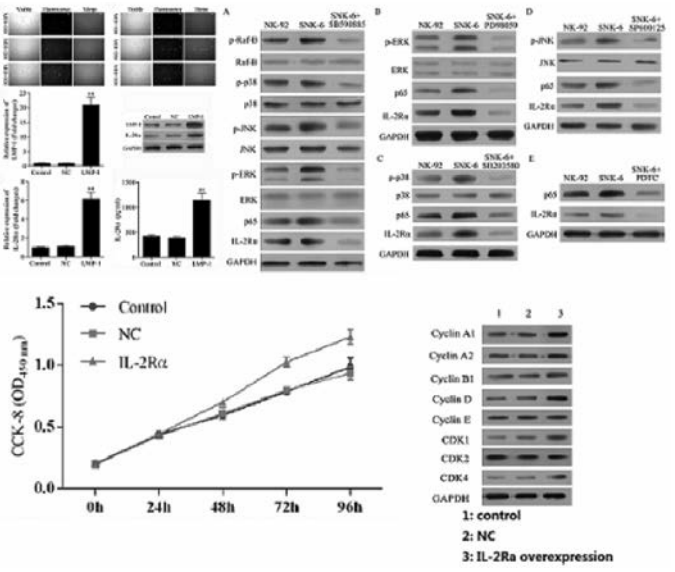

Figure 1.

Results: Expression of IL-2Rα was significantly higher in SNK-6 cells than in NK-92 cells, at both protein and mRNA levels. Expression of IL-2Rα was remarkably upregulated in NK-92 cells transfected with LMP1-harboring lentiviral vectors compared with those transfected with negative control vectors. Proteins in the MAPK/NF-κB pathway were upregulated in LMP1-expressing NK-92 cells compared with the negative control. Selective inhibitors of those proteins induced significant downregulation of IL-2Rα expression in LMP1-expressing NK-92 cells as well as in SNK-6 cells. When comparing with those transfected with negative control vectors, cell growth was significantly increased in both NK-92 and SNK-6 cells transfected with IL-2Rα-harboring lentiviral vectors, and the cell cycle assay displayed a significant decrease in the percentage of cells in the G0/1 phase ($p<0.05$) and an increase in the percentage of cells in the S phase ($p<0.05$), while apoptosis was not affected. Subsequent western blot tests demonstrated that cyclin A, B, D, and CDK1, 4 were involved in the regulation of cell cycle with overexpression of IL-2Rα. The IC50 values to all three chemotherapy drugs were significantly increased after overexpression of IL-2Rα ($p<0.05$), which can be fully reversed by addition of anti-IL-2Rα antibody.
Summary/Conclusions: IL-2Rα expression was upregulated in NKTCL by LMP-1-mediated activation of MAPK/NF-κB pathway. IL-2Rα can promote NKTCL cell proliferation partially through regulation of cell cycles and induce chemotherapy resistance, which can be reversed by anti-IL-2Rα antibody, indicating the potential role of IL-2Rα as a therapy target in NKTCL.

San Martino-IST, Genoa, Genoa, [18]Department of Experimental and Clinical Medicine, University of Catanzaro Magna Graecia, Catanzaro, [19]Scientific Direction, IRCCS-A.O.U. San Martino-IST, Genoa, [20]Hematology Department, Annunziata Hospital of Cosenza, Cosenza, Italy

Background: PD1 binding to its ligand PDL1 inhibits TCR/BCR signaling; impairs activation and effector functions of T- and B-cells; induces a state of T-cell exhaustion; and ultimately provokes tolerance towards cancer cells. PD1 is expressed on Hodgkin lymphoma (HL) and B-cell non-HLT-cells.The TME may play an essential role in maintaining PD1-induced immune exhaustion. LEN is an oral immunomodulator (IMID) with direct antineoplastic activity and immunologic effects, including stimulation of T-cell– and NK cell–mediated cytotoxicity in experimental models.Preclinical findings indicate that combination of IMIDs with immune checkpoints inhibitors may promote therapeutic synergy and long-term antitumor immunity to improve clinical outcome.
Aims: 1) To better characterize the PD1, PDL1 and the lesser-known PDL2, phenotype in peripheral neoplastic CD19+ lymphocytes and T-cell subsets in patients with low-grade B-cell lymphoma; 2)to evaluate the role of the TME in supporting the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression
Methods: Samples obtained from patients attending participating Hematology Units were used to determine PD1, PDL1, PDL2 phenotype (%±SEM) by Flow-cytometry (FC). Autologous activated T-cells (AAT) were obtained by *in vitro* co-culture of patient T-cells with anti-CD3/CD28 beads, rIL2 and with PBMCs. Cultures were monitored daily until sizeable clumping was observed and tested for PD1 and ligand expression. In selected experiments LEN(provided by Celgene) was added to cell cultures.
Results: Twelve cases of lymphoma were evaluated for PD1, PDL1 and PDL2 expression on malignant B- and T-cells by FC. The expression of PD1 and PDL2 was similarly expressed, while PDL1 was almost undetectable on B-cells. Levels of PD1 expression on CD3+ cells were variable across samples, however they were significantly higher than those expressed on malignant B-cells. Significantly higher PD1 expression and very low levels of ligands were detected inboth CD4+ and CD8+ cells.Co-culture of lymphoma cells with AAT cells showed consistent formation of B/T-cell clusters. Higher numbers of CD19+CD5-PDL2+ cells were detected than PDL1+ cells compared to baseline cells. PD1 expression also significantly increased in AAT co-culture on B-cells. PD1 expression

on CD3+ cells was unaffected by AAT, although the expression of both ligands increased significantly. Closer analysis of T-cell subsets showed that only in CD4+ cells, PD1 expression increased significantly following co-culture experiments.Preliminary data on lymphoma-AAT co-culture experiments (n=3) indicated that LEN (0.5/1 uM) did not negatively influence the formation of AAT clusters. After 48 h of co-culture, the expression of CD19+CD5-PDL1+ cells increased in 2/3 cases following LEN treatment while, PDL2 expression remained unchanged. PD1 expression gradually increased following exposure to LEN compared to untreated cells.CD3+ cells showed a significant increase in PD1 expression by LEN, while the expression of both ligands remained unaffected. Evaluation of activated T-cell subsets showed similar results, with the exception of stronger induction of PD1 and PDL1 expression by LEN in CD8+ cells.

Summary/Conclusions: Our data provide support for the potential involvement of the PD1-axis in lymphoma patients. Interestingly, LEN further induces the expression of PD1 in CD8+ and CD4+ cells and may contribute to reactivate PD1 signaling under treatment. The PD1 pathway may be potentially targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

E1391

IDENTIFICATION AND DIAGNOSTIC APPLICATION OF GENOMIC NPM-ALK FUSION SEQUENCES IN ANAPLASTIC LARGE CELL LYMPHOMAS

M. Krumbholz[1,*], C. Damm-Welk[2], W. Woessmann[2], M. Metzler[1]
[1]Department of Pediatrics, University Hospital Erlangen, Erlangen, [2]Department of Pediatrics, Justus-Liebig-University, Giessen, Germany

Background: ALK positive anaplastic large-cell lymphomas (ALCL) account for 10-15% of pediatric Non-Hodgkin lymphomas. Most of these patients carry the chromosomal translocation t(2;5)(p23;q35) resulting in the *NPM-ALK* fusion gene formation. The quantification of *NPM-ALK* fusion transcripts is a well-established tool for diagnostic purposes and risk stratification during the course of treatment.

Aims: Establishment of a PCR based assay to identify patient-specific genomic *NPM-ALK* fusion sequences for a DNA based monitoring of minimal residual disease in ALCL patients. Compared to RNA based methods the quantification of DNA is independent of the gene expression. Additionally, due to the higher stability of DNA, cell-free circulating tumor DNA (ctDNA) should be detectable in the patient´s plasma and may represent a tumor marker for "liquid biopsies" in ALCL.

Methods: Using a specifically designed multiplex long-range PCR assay, genomic *NPM-ALK* fusion sequences were identified in 45 ALCL patients. The genomic *NPM-ALK* breakpoints were analyzed concerning fine structure and breakpoint distribution pattern. Furthermore, the patient-specific genomic *NPM-ALK* fusion sequences were evaluated for their use as biomarkers in selected cases. For this purpose patient´s blood and plasma samples were quantified using a high sensitive digital droplet PCR assay.

Results: In more than 60% of cases the identified breakpoint was localized within repeat regions. The genomic breakpoints within the breakpoint cluster regions of the fusion genes were randomly distributed. Most of the *NPM-ALK* fusion sequences were characterized by the occurrence of small insertions or deletions indicating the involvement of the non-homologous end-joining (NHEJ) repair system for chromosomal translocation initiation.

Using a DNA based quantification assay in a subset of patients, the genomic *NPM-ALK* fusion sequences were detectable in circulating tumor cells in patient´s blood samples as well as cell-free tumor DNA in plasma samples.

Summary/Conclusions: The established multiplex long-range PCR assay is a useful diagnostic tool for the identification of genomic *NPM-ALK* fusion sequences. This individual tumor maker is independent of gene expression and can be used for therapy response monitoring and relapse detection.

E1392

ARSENIC TRIOXIDE TARGETS BCL6 FOR DEGRADATION AND INHIBITS THE PROLIFERATION OF BCL6-DEPENDENT DIFFUSE LARGE B-CELL LYMPHOMA

E. Tse[1,*], K. Yue[1], D. Chau[2], Y.-L. Kwong[1]
[1]Department of Medicine, [2]Medicine, The University of Hong Kong, Hong Kong, Hong Kong

Background: B-cell lymphoma 6 (BCL6) is a transcription repressor and is frequently over-expressed in diffuse large B-cell lymphoma (DLBCL). It suppresses the expression of its target genes ATR, TP53 and CDKN1A, leading to dysregulation of DNA repair and cell proliferation. It has been shown that BCL6 is an oncoprotein involved in the pathogenesis of DLBCL and represents a potential therapeutic target. Arsenic trioxide (ATO) targets various oncogenic proteins, including PML-RARA in acute promyelocytic leukaemia (APL), Tax in adult T-cell leukaemia/lymphoma (ATLL), cyclin D1 in mantle cell lymphoma (MCL), and NPM-ALK in anaplastic large cell lymphoma (ALCL), for degradation through the ubiquitin-proteasome pathway. ATO is now used for the management of APL, ATLL and MCL with proven clinical benefit.

Aims: To investigate if ATO targets BCL6 and inhibits the proliferation and growth of BCL6-dependent DLBCL

Methods: BCL6-dependency of a panel of DLBCL cell lines (*i.e.* OCI-Ly1, OCI-Ly7, SU-DHL-6, OCI-Ly18 and Pfeiffer) was determined based on their sensitivity to proliferation inhibitory activity of the BCL6 inhibitor 79-6 (Calbiochem). The effects of ATO and cisplatin as single agent or in combination on cell viability and apoptosis of DLBCL cells were examined with MTT assay and flow cytometric analysis. Expression of BCL6 and its target genes was examined with quantitative RT-PCR and western immunoblotting. The therapeutic efficacy of ATO treatment was also examined in a DLBCL (OCI-Ly7) xenograft mouse model.

Results: OCI-Ly1, OCI-Ly7 and SU-DHL-6 were highly sensitive to inhibitory activity of BCL6 inhibitor and were designated as BCL6-dependent. Treatment of DLBCL cells with ATO led to a decrease in BCL6 protein level and an upregulation of downstream targets of BCL6, including *PRDM1*, *CD44* and *CD69*. The effect of ATO on BCL6 protein were abrogated by treatment with proteasome inhibitormg132, suggesting that ATO targeted BCL6 for degradation through the ubiquitin-proteasome pathway. Interestingly, ATO also inhibited cell proliferation and induced apoptotic cell death of BCL6-dependent DLBCL cell lines, analogous to the effect of BCL6 inhibitor on these cells. In addition, there was a synergistic inhibitory and cytotoxic activity between ATO and cisplatin. Finally, ATO treatment suppressed the growth of DLBCL in a xenograft mouse model.

Summary/Conclusions: ATO targets BCL6 for proteasomal degradation and inhibits the proliferation and growth of BCL6-dependent DLBCL.

E1393

PROTEOMIC PHOSPHOSITE ANALYSIS IDENTIFIED CRUCIAL NIPA SERINE RESIDUES FOR NPM-ALK-MEDIATED TRANSFORMATION

A. Gengenbacher[1,*], A. Rudorf[1,2], T. Poggio[1], C. Rummelt[1], S. Kreutmair[1], V.I. Dumit[3], J. Duyster[1,2], A.L. Illert[1,2]
[1]Dept. of Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, [2]German Cancer Consortium (DKTK), Heidelberg, [3]Center for Biological Systems Analysis, University of Freiburg, Freiburg, Germany

Background: Anaplastic large-cell lymphoma(ALCL) is an aggressive non-Hodgkin lymphoma that occurs mainly in children and younger adults. Patients typically show an advanced stage disease as well as an aggressive disease pattern with extralymphatic manifestations. At the molecular-genetic level, 60% of the patients with systemic ALCL exhibit a translocation t(2;5)(p23;q35), which leads to the expression of the NPM-ALK fusion protein. Under the control of the NPM promoter, ALK activation causes increased and autonomous cell proliferation. Nuclear interaction partner of ALK (NIPA) was first identified as a new interaction partner of the oncogene NPM-ALK in a yeast-2-hybrid screen which defines an E3-SCF ligase and is physiologically involved in cell cycle regulation at the transition from G2 phase to mitosis. It has already been shown in preliminary studies that co-expression of NIPA with the oncogenic tyrosine kinase NPM-ALK results in the constitutive phosphorylation of NIPA (Illert et al., 2012a). Until now, the specific signal transduction pathway, the crucial phosphorylation sites as well as the functional effect of the pathological NIPA phosphorylation in NPM-ALK-induced lymphomagenesis still remain unclear. Molecular insights into the activated pathways of the oncogenic tyrosine kinase NPM-ALK may help to identifiy new drugable targets for therapeutic implications.

Aims: In the present study, we investigated the molecular mechanisms as well as the functional impact of the NPM-ALK-induced NIPA phosphorylation.

Methods: For this purpose, biochemical methods with ALCL cells were used to examine functional effects of the constitutive NIPA phosphorylation. Moreover, we performed a "proteomic-phosphosite-analysis" to identify crucial NPM-ALK specific phosphorylation sites in NIPA. Based on these results, phospho-deficient NIPA mutants were generated to investigate the functional effect of this phosphorylation: MTT proliferation- and Softagar- Assays were performed after retroviral infection of Ba/F3 and primary Nipa-deficient MEF cells with NPM-ALK and the respective phospho-deficient NIPA to reveal transformation and growth ability.

Results: It has already been shown, that cell cycle dependent NIPA phosphorylation at critical serine residues 354, 359 and 395 leads to dissociation of the SCF-core complex. Interestingly, we were able to show in our study that constitutive phosphorylation of NIPA by NPM-ALK does not lead to changes in the SCF^{NIPA}-complex formation. Proteomic-Phosphosite-analyses identified 10 significantly upregulated (ratio >2; Log2Fold Change) NIPA phosphosites upon NPM-ALK expression. Interestingly, 80% of the identified Serine phosphoresidues lie within the NPM-ALK binding region of NIPA. This result was further substantiated by generation of a AAΔ310-402 mutant, where NIPA phosphorylation by NPM-ALK was totally abolished. To further prove biological significance of the identified residues, phospho-deficient mutants were established and transformation assays were performed. Here we were able to show drastically impaired cell proliferation in mutants with silenced serine/threonine residues 338, 344, 370, 381 and 387 upon NPM-ALK expression.

Summary/Conclusions: Taken together, we identified five phosphorylation sites in NIPA to be highly upregulated upon NPM-ALK expression. However,

NPM-ALK mediated NIPA-phosphorylation of those sites did neither change the SCF^{NIPA}-complex formation nor influence the NIPA localization at the nuclear pore complex, but silencing of these NIPA Serine/Threonine residues led to significantly reduced proliferation and altered transformation ability of Ba/F3 and primary MEF cells. Further analyses will shed some light into the mechanisms underlying these findings and evaluate NIPA as a possible new treatment option for ALCL.

Background: Diffuse large B cell lymphoma (DLBCL) can be divided according to cell of origin (COO) in germinal center B-cell–like (GCB) and activated B-cell–like (ABC) that have been shown different prognosis. Immunohistochemistry (IHC)-based algorithms and recently, Lymph2Cx assay, a digital test based on the expression of 20 genes, have been developed to facilitate COO assignment in clinical practice. Although the importance of COO is well established in DLBCL arising in immunocompetent individuals, its applicability on HIV-infected patients has been scarcely studied.
Aims: To study the characteristics and prognostic impact of COO subtypes in a series of HIV-related DLBCL using the Lymph2Cx assay and to compare the results with those obtained with an IHC-based algorithm.
Methods: A series of 55 patients with the diagnosis of HIV-related DLBCL (N=48), high-grade B-cell lymphoma (HGBL) with MYC and BCL2 and/or BCL6 rearrangements (N=3), or HGBL NOS (N=4) was studied. The following clinical parameters were collected from records: age, gender, ECOG, extranodal and bulky disease, B-symptoms, Ann-Arbor stage, LDH and beta2-microglobulin, HCV and HBV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4-counts and HIV loads. IHC and FISH studies were performed on tissue microarrays. RNA was extracted from FFPE samples with RecoverAll kit (Ambion, Carlsbad, California) and digital GEP was determined with the Lymph2Cx assay (NanoString Technologies, Seattle, WA). Cohen's kappa was calculated to measure the agreement between COO given by Hans algorithm and Lymph2Cx assay.

Table 1.

Characteristic	GCB N=35	ABC N=11	UNC N=9	P-value (GCB vs. ABC)
MYC rearrangement, N(%)	11/32 (34.4%)	0/10 (0%)	2/8 (25%)	0.030
BCL2 rearrangement, N(%)	2/32 (6.3%)	1/10 (10%)	1/8 (12.5%)	0.568
BCL6 rearrangement, N(%)	7/32 (21.9%)	3/10 (30%)	4/8 (50%)	0.444
Dual-hit, N(%)	1/32 (3.1%)	0/10 (0%)	2/8 (25%)	0.762
CD10, N(%)	16/34 (47.1%)	2/11 (18.2%)	1/8 (12.5%)	0.087
BCL6, N(%)	23/33 (69.7%)	4/11 (36.4%)	5/8 (62.5%)	0.055
MUM1, N(%)	16/33 (48.5%)	7/11 (63.6%)	6/8 (75%)	0.384
CD30, N(%)	4/33 (12.1%)	1/11 (9.1%)	3/8 (37.5%)	0.633
EBER, N(%)	5/33 (15.2%)	4/11 (36.4%)	2/8 (25%)	0.141
BCL2, N(%)	12/31 (38.7%)	6/11 (54.5%)	4/8 (50%)	0.287
MYC, N(%)	12/32 (37.5%)	2/11 (18.2%)	3/9 (33.3%)	0.213
Dual expressers, N(%)	6/31 (19.4%)	2/11 (18.2%)	1/8 (12.5%)	0.655

Abbreviations: ABC, activated B-cell–like GCB; GCB, germinal center B-cell–like; UNC, unclassified.

Results: The median follow-up of living patients was 8.5 years. IHC studies showed that 35.8% of the cases expressed CD10, 61.5% expressed BCL6, 55.8% expressed MUM1, and according to Hans algorithm 56.6% had a non-GC phenotype. CD30 was expressed in 15.4% of the cases and EBER was found in 21.2%. The expression of MYC was detected in 32.7% of the cases and BCL2 in 44%, and 18% were dual expressers. Rearrangements involving MYC, BCL2 and BCL6 were detected in 26%, 8% and 28%, respectively. The Lymph2Cx assay assigned a COO to all 55 studied cases, 63.6% were GCB subtype, 20% were ABC subtype, and 16.4% were unclassified. The only clinical feature significantly associated with a defined COO subtype was B-symptoms (ABC=81.8% *vs* GCB=28.6%, P=0.003) and HIV-load tended to be more frequently observed in ABC (90%) than in GCB (58.1%, P=0.066). Regarding IHC and FISH results, MYC rearrangements were only detected in GCB cases and expression of CD10 and BCL6 tended to be associated with GCB (Table 1). Hans algorithm and Lymph2Cx assay differently assigned COO subtypes (κ=-0.288, P=0.029) showing that 44.1% of the GCB cases had a non-GC phenotype according to Hans. Only patients treated with RCHOP were considered in survival analyses (N=47). COO subtypes had neither impact on OS nor PFS, independently of being determined with Hans or Lymph2Cx assay. Features associated with shorter OS and PFS were history of AIDS-defining illnesses, HCV-infection and dual MYC and BCL2 expression. Extranodal disease and increased MYC or BCL2 expression were also bad prognostic factors for PFS.
Summary/Conclusions: In HIV-related lymphomas, COO subtypes were discordantly assigned with Hans and Lymph2Cx assay and COO subtypes showed no impact on outcomes, independently of the method applied.

E1395

CXCR4 AND CXCL12 ARE IMPLICATED IN BONE MARROW INFILTRATION PROCESS OF AGGRESSIVE B CELL LYMPHOMAS AND THEIR INHIBITION SUPPRESSES LYMPHOMA CELL GROWTH *IN VITRO*

A. Deutsch[1,*], B. pursche[1], B. Ehall[1], M. Zoidl[2], K. Fechter[1], E. Steinbauer[3], M. Sedej[4], H. Greinix[1], K. Prochazka[1], T. Wrodnigg[2], C. Beham-Schmid[3], P. Neumeister[1]
[1]Hematology, Internal Medicine, [2]Organic Chemistry Technical University Graz, [3]Pathology, [4]Experimental and Clinical Pharmakology, Graz, Austria

Background: The chemokine receptor CXCR4 together with its prime ligand CXCL12 plays a pivotal role in tumorigenesis of solid and haematological neoplasms. Our comprehensive study on the CXCR4 expression in aggressive lymphoma demonstrated that high CXCR4 expression was associated with poor clinical course of aggressive lymphoma patients.
Aims: Therefore, we aimed to comprehensively study the implication of the CXCR4 - CXCL12 axis in bone marrow infiltration process of aggressive lymphoma and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells *in vitro.*
Methods: To determine whether *CXCR4* and *CXCL12* expression have any effects on the bone marrow infiltration process of aggressive lymphomas, we performed gene expression analysis on bone marrow biopsies of our diffuse large B-cell lymphoma patient cohort. Therefore, we used 63 bone marrow specimens, whereby 52 bone marrow biopsies were taken at time of diagnosis. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AMD070 - a commercially available CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonists (AMD070 and its derivate WK-1 and the FDA approved CXCR4 antagonist AMD3100) and determined cell growth by using the EZ4U assay. Transwell migration using the Boyden chamber was used to estimate migration indices for AMD070 and WK-1.
Results: By correlating *CXCL12* expression levels of infiltrated bone marrow biopsies, we observed a significant positive correlation between *CXCL12* expression and the percentage of infiltration levels (Spearman-Rho=0.764; p=0.001). Furthermore, remission inthe bone marrow after standard immunochemotherapy was associated with a reduction of *CXCR4* expression (p=0.075). The cell growth of BL2 and RI-1 cell lines -exhibiting strong and moderated CXCR4 expression- was significantly inhibited by AMD070 and WK1. Whereas the cell growth of U2932 -exhibiting a weak CXCR4 expression- was just affected by WK1. AMD3100 did not show any effects on the lymphoma cell growth. The transmigration index to evaluate the chemotactic ability of lymphoma cells was reduced by AMD070 and WK1 treatment, however, the inhibitory effects of WK1 were lower compared to AMD070.
Summary/Conclusions: These data strongly suggest that *CXCR4* and its ligand *CXCL12* is implicated in the bone marrow infiltration process of diffuse large B-cell lymphomas. Additionally, our *in vitro* results indicate that treatment of lymphoma cells with CXCR4 antagonists might be a promising new therapeutic intervention to eliminate lymphoma cells.

EPSTEIN-BARR VIRUS LOAD IN PLASMA IS AN EARLY BIOMARKER OF HIV-RELATED LYMPHOMA

J. Muncunill[1,*], M.J. Baptista[1], A. Hernandez-Rodriguez[2], J. Dalmau[3], O. Garcia[1], G. Tapia[4], M. Moreno[1], J.-M. Sancho[1], J. Martinez-Picado[5], J.-M. Ribera[1], E. Feliu[1], J.-L. Mate[4], J.-T. Navarro[1]
[1]Department of Hematology, ICO-Hospital Universitari Germans Trias i Pujol, Josep Carreras Leukaemia Research Institute, Universitat Autònoma de Barcelona, [2]Department of Microbiology, Hospital Universitari Germans Trias i Pujol, [3]AIDS Research Institute-IrsiCaixa, Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Universitat Autònoma de Barcelona, [4]Department of Pathology, Hospital Universitari Germans Trias i Pujol, Universitat Autònoma de Barcelona, [5]AIDS Research Institute-IrsiCaixa, Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Universitat Autònoma de Barcelona,nstitució Catalana de Recerca i Estudis Avançats (ICREA), Badalona, Spain

Background: Epstein Barr virus (EBV) has been detected in the tumor cells of some non-Hodking lymphomas (NHL) and Hodgkin lymphomas (HL) and detectable EBV loads have been found in the plasma of immunocompetent patients with HL. In HIV-related lymphomas the importance of EBV load as potential lymphoma biomarkers has been scarcely studied.
Aims: We aimed to evaluate the usefulness of EBV load in plasma as lymphoma biomarker in HIV-infected patients.
Methods: One hundred and fifteen patients with NHL (HIV-infected =57 and HIV-uninfected=34) and HL (HIV-infected= 16 and HIV-uninfected= 8) were studied. EBV loads were determined in plasma by means of a commercial real-time PCR technique (EBV PCR kit, Qiagen GmbH, Hilden, Germany) at lymphoma diagnosis and in a group of HIV-infected patients also at one year before diagnosis (N=11) and at complete response (CR) (N=34). EBER expression was studied by *in situ* hybridization in tumor biopsies. The following clinical and biological parameters were collected from records: age, gender, date of lymphoma diagnosis, ECOG score, extranodal and bulky disease, B symptoms, Ann-Arbor stage, serum lactate dehydrogenase and beta2-microglobulin, International Prognostic Index (IPI), HCV and HBV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4-counts, HIV loads, type and date of response, relapse date, last follow up or death date. McNemar's test and Wilcoxon test were used to compare quantitative and qualitative variables, respectively. Survival analyses were performed using the Kaplan-Meier method. P-values of less than 0.05 were considered statistically significant.

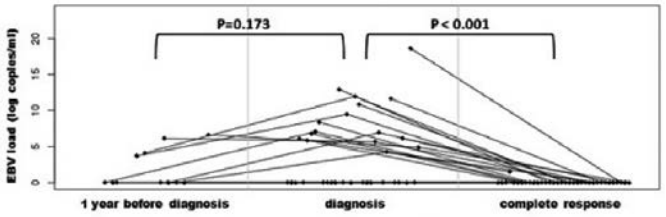

Figure 1. EBV loads of HIV-infected patients with lymphoma at three clinical points. Lines connect EBV determinations of the same patient.

Figure 1.

Results: At diagnosis, EBV loads were detectable in more HIV-infected patients than HIV-uninfected (48% *vs* 14%, P=0.002) and in more HL cases than NHL (70% *vs* 26.3%, P=0.006). In HIV-infected patients, detectable EBV load was associated with EBER expression, 66.6% of the patients with detectable EBV loads had EBER-positive tumors and 92% of the patients with undetectable EBV loads had EBER-negative tumors (P=0.003). All the remaining clinical and biological features were not associated with detectable EBV load in plasma. In HIV-uninfected patients, associations between EBV load and EBER expression (P=0.006) and EBV load and HBV infection (P=0.017) were observed. From 16 out of 34 (47%) HIV-infected patients with detectable EBV loads at lymphoma diagnosis, 15 had undetectable EBV loads at CR (P<0.001) (Figure 1). The exception was one patient with HL whose EBV load substantially decreased at CR but was still detectable. Moreover, 4 out of 7 HIV-infected patients with detectable EBV loads at diagnosis had detectable loads one year before diagnosis, and no patient with negative EBV loads at diagnosis had detectable loads before it, pointing EBV load can be used as an early biomarker of lymphoma. EBV loads at diagnosis had neither impact on overall survival nor progression-free survival.
Summary/Conclusions: EBV-load in plasma can be used as early biomarker of lymphoma in HIV-infected patients since EBV-loads can be detected up to 1 year before lymphoma diagnosis and are virtually undetectable at lymphoma CR.

CLONOTYPE AND MUTATIONAL PATTERN IN TCRGD LARGE GRANULAR LYMPHOCYTE LEUKEMIA

A. Teramo[1,2,*], E. Ciabatti[3], G. Tarrini[3], I. Petrini[4], G. Barilà[1], G. Calabretto[1,2], C. Vicenzetto[1,2], M. Leoncin[1,2], C. Ercolin[1], A. Cabrelle[2], S. Galimberti[3], R. Grossi[5], N. Pisanti[5], G. Semenzato[1,2], R. Zambello[1,2]
[1]Department of Medicine, Hematology and Clinical Immunology Branch, Padua University School of Medicine, [2]Venetian Institute of Molecular Medicine (VIMM), Padova, [3]Department of Clinical and Experimental Medicine, Section of Hematology, [4]Department of Translational Research and New Technologies in Medicine, Section of Pathology, [5]Department of Informatics, University of Pisa, Pisa, Italy

Background: T-cell large granular lymphocyte leukemia (T-LGLL) is a rare heterogeneous T-cell neoplasia whose leukemic cells usually express the αβ T-cell receptor (TCR); only a small subset of cases expresses the γδ TCR denoting the TCRγδ LGLL. Currently, among the different LGL diseases, TCRγδ LGLL remains less studied and several clinical and laboratory data already described in TCRαβ-LGLL have not yet been explored in TCRγδ-LGLL.
Aims: The aims of this work were 1) to characterize TCRγδ-LGLL defining *STAT* mutational pattern and CDR3 repertoire diversity/clonal composition (clonotype) and 2) to evaluate correlations among LGL phenotype, mutations, TCR rearrangement and clinical presentations.
Methods: In this work 11 patients affected by TCRγδ-LGLL were included. Sanger sequencing was used for mutational analysis on hot-spot regions in the two genes more frequently mutated in LGL disorders, *STAT3* and *STAT5b*. Immunophenotype of LGL clone was defined by flow cytometer analysis. CDR3 repertoire and frequency distribution of TCR gamma gene rearrangements were obtained by Next-Generation Sequencing (NGS).
Results: Our results showed that TCRγδ LGLL had a high incidence of *STAT* mutations, 9 out of 11 patients carrying *STAT3* or *STAT5b* mutations in a mutually exclusive pattern. At variance from CD8+ TCR αβ LGLL and CD4+ TCR αβ LGLL, the first being mostly characterized by *STAT3* mutations and the latter by *STAT5b*, TCRγδ LGLL patients were characterized by both the mutations. Thus, TCRγδ LGLL showed features shared by CD8 and CD4 TCRαβ-LGLL. Consistently, TCRγδ LGLL showed the same correlation between immunophenotype and kind of mutation observed in TCRαβ-LGLL: γδLGL patients with CD16+/CD56- LGL immunophenotype were characterized by *STAT3* mutations (as in CD8+ T-LGLL), while γδLGL patients with CD56+ LGL immunophenotype by *STAT5b* mutations (as in CD4+ T-LGLL). Moreover, we observed that patients with γδLGLs positive for Vδ2 showed usually indolent course, while Vδ1 was linked to a more symptomatic disease (4 out of 5 symptomatic patients were Vδ1+), whereas no correlation was found between mutations and clinical course. By NGS of TCR gamma gene, we observed that all patients were clonal but two, showing a polyclonal pattern borderline with clonality percentage defined by sequencing kit criteria. Interestingly, these two last patients were the only two patients without *STAT* mutations. As far as the remaining cases are concerned, among *STAT3* mutated patients (n=4), 3 were polyclonal and one biclonal, while *STAT5b* mutated patients (n=5) were more frequently monoclonal (4/5 monoclonal and 1/5 biclonal). In terms of clonal rearrangements, Vg3-Jg1/2, Vg9-JgP and Vg8Jg1/2 were the combination usages most frequently detected. Concerning the clonotype repertoire, CDR3 sequences of the immunodominant clones were present with low frequency in almost all the other γδ patients and two different CDR3 sequences were found shared, each one in two different patients at frequency >10% of the total rearrangements.
Summary/Conclusions: Our data indicate that TCRγδ LGLL can be considered at the intersection of the two types of TCRαβ-LGLL, sharing CD8 or CD4 TLGLL mutational features. As already described in TCRαβ-LGLL, also in γδ disease a decreased diversity of TCR repertoire was demonstrated. However, in these γδLGL patients *STAT* mutations do not correlate with a symptomatic clinical behavior while *STAT5b* mutations seems to be more frequently linked to monoclonal nature of the LGL lymphoproliferation. Rather, the marker Vδ1 appears to be correlated to symptomatic disease.

E1398

INCREASED EXPRESSION OF IRF8 IN TUMOR CELLS INHIBITS THE GENERATION OF TH17 CELLS AND PREDICTS UNFAVORABLE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS

Q. Li[1,*], W. Zhong[1]
[1]Guangzhou First People's Hospital, Guangzhou Medical University, Guangzhou, China, Guangzhou, China

Background: The immunological pathogenesis of diffuse large B cell lymphoma (DLBCL) remains elusive. Searching for new prognostic markers of DLBCL is a crucial focal point for clinical scientists.
Aims: The aim of the present study was to examine the prognostic value of interferon regulatory factor 8 (IRF8) expression and its effect on the development of Th17 cells in the tumor microenvironment of DLBCL patients.
Methods: Flow cytometry, immunohistochemistry, and quantitative real-time PCR were used to detect the distribution of Th17 cells and related cytokines and IRF8 in tumor tissues from DLBCL patients. Two DLBCL cell lines (OCI-

LY10 and OCI-LY1) with IRF8 knockdown or overexpression and two human B lymphoblast cell lines were co-cultured with peripheral blood mononuclear cells (PBMCs) *in vitro* to determine the effect of IRF8 on the generation of Th17 cells. Quantitative real-time PCR and Western blotting were used to investigate the involvement of retinoic acid receptor-related orphan receptor gamma t (RORγt) in the effect of IRF8 on Th17 cell generation. The survival of 67 DLBCL patients was estimated using the Kaplan-Meier method and log-rank analysis.
Results: The percentage of Th17 cells was lower in DLBCL tumor tissues than in PBMCs and corresponding adjacent benign tissues. Relative expression of interleukin (IL)-17A was lower, whereas that of interferon (IFN)-γ was higher in tumor tissues than in benign tissues. Co-culture with DLBCL cell lines inhibited the generation of Th17 cells *in vitro*. IRF8 upregulation was detected in DLBCL tumor tissues, and it was associated with decreased DLBCL patient survival. Investigation of the underlying mechanism suggested that IRF8 upregulation inhibited Th17 cell generation by suppressing the effect of RORγt on CD4+ T cells.
Summary/Conclusions: Our findings suggest that IRF8 expression in the tumor microenvironment inhibited the generation of Th17 cells through its antagonistic effect on RORγt in the DLBCL tumor microenvironment, suggesting that it could be a prognostic factor for DLBCL.

E1399

GENOMIC PROFILING OF BCL2 AND MYC DOUBLE EXPRESSOR DIFFUSE LARGE B CELL LYMPHOMA

V. Dirse[1,2,*], J. Drachneris[3], U. Mickys[3], M. Stoskus[1], L. Griskevicius[1,2]
[1]Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, [2]Department of Internal, Family Medcine and Oncology, Faculty of Medicine, Vilnius University, [3]National Center of Pathology, Affiliate of Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive disease featuring heterogeneous genetic, phenotypic and clinical characteristics. Recently, a negative prognostic impact of double expression of BCL2 and MYC (double expressor (DE) lymphoma) has been identified in several studies. SNP array (SNP-A) studies have already led to the identification of novel genomic aberrations in ABC and GCB subtypes of DLBCL whereas similar analysis has not been done in DE and non-DE DLBCL.
Aims: To characterize the landscape of genomic aberrations in DE and non-DE DLBCL groups using SNP-A and interphase fluorescence *in situ* hybridization (FISH).
Methods: Immunohistochemical and FISH analysis was performed on tissue microarray of formalin fixed paraffin embedded (FFPE) tumor tissue samples using Bcl2 (124, DakoCytomation) and MYC (Y69, Epitomics) antibodies and FISH MYC (Zytovision), Bcl2 (Abbott/Vysis), Bcl6 (Abbott/Vysis) break-appart probes and MYC/IgH (Zytovision) double-fusion probe. Infinium HD whole-genome genotyping assay with the HumanCytoSNP FFPE-12 BeadChip (Illumina Inc., San Diego, CA, USA) was performed for genomic analysis of the aberrations.
Results: A cohort of 91 primary DLBCL patients diagnosed between 2004 and 2012 was selected for the study. Immunohistochemical evaluation was informative in 84 cases, 25 cases (29.8%) were DE. On FISH analysis, 61 cases were informative for MYC, 56 cases for Bcl6, and 65 cases for Bcl2. 7 cases (11.4%) were positive for MYC translocation, 14 (25%) for Bcl6, and only 3 (4.6%) were positive for Bcl2. No cases of FISH MYC and bcl2 double positive DLBCL were identified. Genomic DNA from FFPE tumor tissue for SNP-A was available in 66 DLBCL cases. SNP-A analysis detected in total 329 genetic abnormalities not corresponding to known copy number polymorphisms (89% of all the patients, 59/66). These comprised 164 (50%) hemizygous and 2 (1%) homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q deletion and 3q gain. Complex karyotype (>3 aberrations) was detected in 37/66 (56%) patients. Both DE and non-DE DLBCL groups had equal rate of aberrations per case (~5 aberr./case) and shared the most common aberrations – 1p deletion and 1q gain. In contrast, 11q deletion was more common in DE, while 6q and 17q deletions were more prevalent in the non-DE had group. Notably, we detected a higher proportion of hyperdiploidic karyotypes in non-DE group than in DE (16 *vs* 6 cases, respectively). Cases with MYC positive (FISH) and MYC gain (SNP-A) had the median number of two chromosomal aberrations with an exception of two MYC positive cases with complex karyotypes. These two cases shared the same 9q, 11q, 14q deletions and the monosomy of chromosome 19. Finally, of the 7 cases with normal SNP-A karyotype, BCL6 FISH-positive marker was detected in 3 patients.
Summary/Conclusions: SNP-A analysis highlights the genomic differences between the DE and non-DE DLBCL. Our finding of MYC positive (translocations and/or gains) association with low complexity karyotype status may suggest MYC to be an early initiating genetic event.

E1400

ARQ 531, A REVERSIBLE BTK INHIBITOR, DEMONSTRATES POTENT ANTI-TUMOR ACTIVITY IN ABC-DLBCL AND GCB-DLBCL

S. Eathiraj[1,*], Y. Yu[1], T. Hall[1], B. Schwartz[1], J.A. Woyach[2], S. Reiff[2], G. Abbadessa[1]
[1]Clinical Development, ArQule Inc.,, Burlington, [2]Division of Hematology, The Ohio State University, Columbus, United States

Background: B-cell receptor (BCR) signaling has emerged as a critical pathway for B-cell lymphoma development. BTK, a key mediator of BCR signaling is a major target for ibrutinib. Ibrutinib has demonstrated efficacy in chronic lymphatic leukemia (CLL), mantle cell lymphoma and Waldenström macroglobulinemia. However, as anticipated by preclinical models, clinical objective response rates of only 37% in ABC and 5% in GCB diffuse large B cell lymphoma (DLBCL) were reported. ARQ 531 is a potent reversible inhibitor of BTK, highly effective in targeting BCR signaling. Kinase profiling indicated members of Tec, Src, Trk families as additional targets with especially potent inhibition of HCK and BLK kinases. ARQ 531 caused significant growth inhibition (GI_{50}=< 1μM) of hematological malignant cell lines and and showed greater efficacy than ibrutinib in a CLL mouse model.
Aims: We aim to assess biological and anti-tumor effects of ARQ 531 in *in vitro* and *in vivo* in DLBCL tumor models.
Methods: Biochemical inhibition and kinase profiling were assessed using recombinant proteins. The ARQ 531 binding kinetics on BTK were determined by Surface Plasmon Resonance assay. Anti-proliferative activity of ARQ 531 was tested in a MTS-based assay against a panel of hematological malignant cell lines. Pathway inhibition assessments, *in vivo* efficacy and *in vivo* target inhibition were performed in TMD8 (ABC-DLBCL) and SUDHL-4 (GCB-DLBCL) cell lines and xenografts. ADME and pharmacokinetic properties of ARQ 531 were also evaluated in rats, dogs and monkeys.
Results: ARQ 531 potently inhibited BTK (IC50=0.85 nM) and displayed long residence time (56 min). ARQ 531 exhibited strong anti-proliferative activity in TMD8 (GI_{50}=0.13 μM) and SUDHL-4 (GI_{50}=0.2 μM) cell lines. Ibrutinib, while potent on TMD8 cells (GI_{50}=0.002 μM), had a GI_{50} of 1.1 μM in SUDHL-4, a concentration not reached in human blood, consistent with published studies. Pathway analysis in TMD8 and SUDHL-4 cells showed that ARQ 531 potently inhibited both upstream activating signals (Src kinase family) and downstream signaling pathways such as AKT and ERK. Cell cycle analysis indicated that ARQ 531 inhibited cell growth through G1 phase arrest, similar to ibrutinib. In the TMD8 xenograft mouse model, ARQ 531 strongly inhibited BTK signaling, with better efficacy than reported with ibrutinib: tumor growth reduction was 97% after 12 days of dosing, with no re-growth observed for 17 days post dose interruption. In the ibrutinib-resistant SUDHL-4 mouse xenograft model, ARQ 531 potently suppressed tumor growth (>80% inhibition) compared to the control group.
Summary/Conclusions: ARQ 531 is a potent reversible inhibitor of BTK. Its distinct kinase selectivity can be used to target constitutive BCR signaling in DLBCL primarily resistant to ibrutinib, as demonstrated by the excellent efficacy in both ABC and GCB DLBCL xenograft models. These data support the clinical investigation of ARQ 531 in patients with hematological malignancies, expected to begin in mid-2017.

E1401

ROLE OF GENETIC POLYMORPHISMS ON R-CHOP EFFICACY IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: AN INTERIM ANALYSIS OF A MULTICENTER PROSPECTIVE PHARMACOGENETIC STUDY

L. Rigacci[1,*], G. Perrone[2], S. Nobili[3], S. Kovalchuk[1], B. Puccini[1], R. Tassi[2], M. Brugia[2], I. Landini[2], L. Mannelli[1], G. Benelli[1], C. Napoli[3], E. Cencini[4], A. Fabbri[4], L. Iovino[5], M. Petrini[5], S. Birtolo[6], A. Melosi[7], S. Santini[8], P. Bernardeschi[9], A. Bosi[1], E. Mini[2]
[1]Haematology, AOU Careggi and University of Florence, [2]Medicina Sperimentale e Clinica, [3]Scienze della Salute, University of Florence, Florence, [4]Haematology, AO Siena, Siena, [5]Haematology, AOU Pisa, Pisa, [6]Oncologia, Ospedale Pescia, Pescia, [7]Oncologia, Ospedale Lucca, Lucca, [8]Oncologia, Ospedale Prato, Prato, [9]Oncologia, Ospedale Empoli, Empoli, Italy

Background: Standard chemotherapy represented by the R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) regimen is successful in about 60% of patients (pts) with diffuse large B-cell lymphoma (DLBCL). Pts who do not benefit from this treatment, due to the development of tumor drug resistance, have a very poor prognosis. Currently, knowledge on reasons of treatment related failures in DLBCL are scanty and predictive biomarker of response are largely unknown.
Aims: We hypothesized that polymorphisms of gene involved in the pharmacokinetics and pharmacodynamics of drugs included in R-CHOP regimen may play a role in predicting the outcome in DLBCL pts. Thus, we designed a multicentre prospective pharmacogenetic trial aimed at identifying gene polymorphisms potentially predictive of drug efficacy/resistance in DLBCL pts treated with R-CHOP. We are reporting update data of an interim analysis on the first 80 enrolled pts.
Methods: The study includes chemonaive DLBCL pts (Ann Arbour I-IV stages) candidate to an R-CHOP standard treatment. The Ethical Committee of each participating centre approved the pharmacogenetic protocol, and all pts signed a written informed consent. In this interim analysis, the impact of single nucleotide polymorphisms (SNPs) on R-CHOP efficacy was evaluated by objective response (OR) rate, progression-free survival (PFS) and overall sur-

vival (OS).The efficacy of R-CHOP was evaluated according to Cheson criteria by performing standard hematochemical and instrumental (TC and FDFG-PET) tests and defining complete remission (CR), partial remission (PR), non response or progressive disease (PD). Genomic DNA was extracted from peripheral blood of 80 pts. SNPs analysis was performed by an Affimetrix array. To date, 21 SNPs from 19 candidate genes (*ABCB1, ABCC1, ABCC2, ABCG2, CYBA, CYP2C9, FCGR2A, GSTP1, IL2, MARCKS, MLH1, NCF4, NQO1, NQO2, RAC2, TNF, TOP2A, TP53, TUBB*) involved in pharmacokinetics and pharmacodynamics of R-CHOP (www.pharmgkb.org) selected and analysed in relation to R-CHOP efficacy. Univariate and multivariate logistic regression analyses were performed to evaluate associations between SNPs and clinical/pathological characteristics or survival parameters (PFS and OS).
Results: Median age was 63 years. There were 37 men and 43 women. 47.5% of pts were in stage I-II, 52.5% of pts in stage III-IV. 27.5% of pts had bulky disease, 43.8% of pts had involvement of extranodal site. 47.5% of pts had pathological LDH value. According to the revised IPI, 15% of pts were in the low risk group, 58.7% in the intermediate, and 26.3% in the high risk group. Overall, 468 courses of R-CHOP had been administered (mean: 5.85 courses, range: 4-6). 88,7% of pts had CR to R-CHOP whereas the remaining showed PR or SD (7.5%) or PD (3,8%). Multivariate analysis identified *FCGR2A* rs1801274 as a predictor of PFS (p=0.045). Pts with HR or RR genotypes showed shorter PFS than pts with HH genotype (HR: 2.437, CI95% 1.020-5,823). No statistically significant correlation was found between SNPs and OS.
Summary/Conclusions: Our preliminary data obtained in a limited number of pts, show an association between a SNP of the low affinity *FCGR2A* gene involved in the activity of rituximab and PFS. Further insights will derive from the completion of pts accrual to reach the planned number of cases at the end of our study.

CDK4/6-INHIBITION BY ABEMACICLIB INDUCES POTENT EARLY G1-ARREST IN MCL CELL LINES AND SHOWS SEQUENCE-SPECIFIC INTERACTIONS WITH CYTARABINE AND IBRUTINIB

L. Fischer[1,*], A. Mayer[1], M. Irger[1], B. Freysoldt[1], Y. Zimmermann[1], G. Hutter[1], W. Hiddemann[1], M. Dreyling[1]
[1]Dept. of Medicine III, Univ. Hospital Grosshadern/LMU; Experimental Leukemia and Lymphoma Research (ELLF), Munich, Germany

Background: Mantle cell lymphoma (MCL) is characterized by t(11;14) resulting in a constitutive cyclin D1 overexpression. The cyclin D1-CDK4/6 complex inactivates Rb through phosphorylation, leading to G1/S-phase transition. Therefore, inhibition of CDK4/6 is an efficient and rational approach to overcome cell cycle dysregulation in MCL.
Aims: We evaluated the efficiency of the novel CDK4/6 inhibitor abemaciclib in various MCL cell lines and in primary MCL cells in combination with cytarabine (AraC) and ibrutinib.
Methods: MCL cell lines (Granta 519, JeKo-1, Maver-1, Mino) and primary MCL cells were exposed to abemaciclib alone and combined with AraC or ibrutinib. Cells were pretreated with abemaciclib and exposed to AraC or ibrutinib with or without consecutive wash-out of the CDK4/6 inhibitor. Proliferation and viability were measured by trypan blue staining and Cell Titer Glo assay. Combination Index (CI) to assess synergy or antagonism was calculated using the Fractional Product method by Webb (1963). Flow cytometry was applied for cell-cycle (PI-staining) and apoptosis analysis (Annexin V PE/7AAD-staining). Protein expression and phosphorylation status of various downstream proteins was analyzed by Western Blot analysis.
Results: Abemaciclib inhibited cell proliferation by induction of early G1-arrest. We observed an almost complete and reversible G1-arrest in all sensitive cell lines by FACS analysis (JeKo-1: *G1-phase +51,7%; S/G2-phase -51,7%* at 31,25 nM after 24 h; *G1-phase +35,4%; S/G2-phase -34,8% after 72 h*), whereas cell viability was not reduced. IC50-values of sensitive cell lines (JeKo-1, Maver-1, Mino) were <30 nM after 72 h. Western Blot analysis revealed reduced phosphorylation of Rb on serine 795 without changes in CDK 4 and cyclin D1 expression, in line with reversible cell cycle arrest. Wash-out of abemaciclib after 24 h resulted in synchronized S-phase entry in all sensitive cell lines (e.g. Mino: *G1-phase -20,4%; S-phase +30,5%*). Accordingly, sequential combination of abemaciclib followed by AraC showed strong synergy in Mino cells (*CI=0,22* for 31,25 nM abemaciclib / 3,33 µM AraC). In contrast, simultaneous exposure to abemaciclib had a protective effect against AraC treatment in all sensitive cell lines, due to an ongoing G1-arrest (Mino: *CI=-0,19* for 31,25 nM abemaciclib / 3,33 µM AraC). Sequential administration of abemaciclib and ibrutinib had synergistic or additive effects in sensitive cell lines (*CIs:* JeKo-1=*0,24*; Maver-1=*0,19*; Mino=*-0,03* for 31,25 nM abe / 2,5 µM ibru), whereas the simultaneous administration of both showed additive effects at most (*CIs:* JeKo-1=*0,02*; Maver-1=*-0,1*; Mino=*-0,09* for 31,25 nM abe and 2 µM ibru). In primary MCL cells abemaciclib had no impact on cell death or sensitization since no cell proliferation was observable and cells where resting in G1-phase.
Summary/Conclusions: The novel CDK4/6 inhibitor abemaciclib causes reversible G1 cell cycle arrest without loss of viability at low nanomolar doses. Rationale drug combinations exploiting the sequential effect may achieve major benefits. Pretreatment with abemaciclib might sensitize cells to ibrutinib, resulting in synergistic drug effects. In contrast, simultaneous application of Abemaciclib protects cells from AraC treatment whereas Abemaciclib-induced S-phase synchronization sensitizes MCL cell lines to AraC. Further analysis need to explore the interaction with other targeted approaches (inhibitors of the B-cell receptor pathway) to better understand the underlying molecular mechanisms.

E1403

CD8+ T-CELL CLONES PERSISTENT IN BONE MARROW AND PERIPHERIAL BLOOD DURING COURSE OF CD4+ ANGIOIMMUNOBLASTIC LYMPHOMA

S. Smirnova[1,*], Y. Sidorova[1], N. Chernova[2], E. Zvonkov[2], M. Sinicina[3], K. Sychevskaya[4], O. Glinshchikova[1], N. Ryzhikova[1], A. Kovrigina[3], A. Sudarikov[1]
[1]Department of Molecular Hematology, [2]Department of Lymphoma Chemotherapy, [3]Department of Pathology, National Research Center for Hematology, [4]Faculty of Basic Medicine, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) – peripheral T-cell lymphoma, characterized by polymorphous infiltration of the lymph nodes, proliferation of high endothelial venules (HEV) and follicular dendritic cells (FDC). In addition to the lymph nodes, AITL affects spleen, liver, skin and bone marrow. The disease is almost always associated with Epstein-Barr virus (EBV), suggesting its role in the etiology of AITL. Neoplastic T cells in most cases are CD4+ and express pan T-cell antigens CD3, CD2, CD5, markers of normal follicular T-helper cells – CD10, CXCL13, PD-1. To confirm the diagnosis and assess disease dissemination combined morphological, immunohistochemical and molecular studies of affected tissues are being used. We have found that T-cell clones detected in the tissue of the lymph node (LN), often differ in T-cell receptor gene rearrangements from those detected in the bone marrow (BM), peripheral blood (PB) and other tissues. T-cell clonality testing itself may not distinguish between neoplastic or reactive lymphoproliferation in the BM and PB. Therefore, T-cell clonality of CD4+ and CD8+ populations of peripheral blood lymphocytes in patients with AITL had been tested during the course of disease.
Aims: To determine immunological characteristics of persisting in the PB and BM T-cell clones in AITL patients.

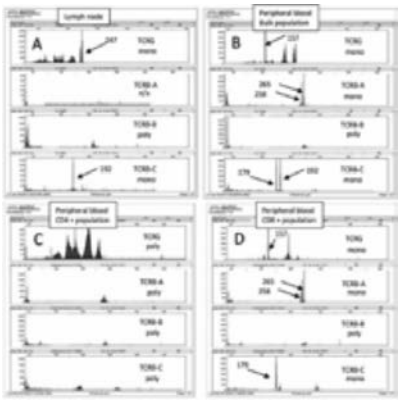

Figure 1.

Methods: The study included 26 patients (15 males and 11 females; age 36-92, median 67) with the diagnosis of AITL established on the basis of WHO 2008 diagnostic criteria. LN, BM and peripheral blood lymphocytes were tested for T-cell clonality according to BIOMED-2 protocol with subsequent fragments analysis on ABI PRISM 3130 (Applied Biosystems). The material was examined at the diagnosis and at various stages of patient's treatment. In 5 patients selection of CD8+ and CD4+ populations of PB lypmphocytes was performed with MidiMACS and MiniMACS Separators using CD4+, CD8+ MicroBeads (Miltenyi Biotec).
Results: Clonal TCRG and TCRB gene rearrangements in the LN of all AITL patients were found. In 6 of the 26 patients (23%) clonal products found in LN matched those from PB and BM. In 8 patients (30%) at least one of the clonal products isolated from the BM and/or PB mismatched the clonal products isolated from LN. In 12 patients (46%) clonal rearrangements found in the PB and BM were completely different from those identified for LN. Thus, at the diagnosis 20 patients (76%) had PB and BM T-cell clones distinct from LN T-cell clones. In 14 of 20 patients T-cell clones of PB and BM were tested repeatedly during the course of disease treatment. In 7 of 14 patients (50%) clonal products persisted for a long time and do not disappear upon reaching the remission of the disease. The observation period averaged 12 months (1 to 44 months). No correlation of T-cell clones persistence and the activity of EBV infection in the PB was found. Selection of CD4+ and CD8+ T-lymphocyte populations was performed for 4 patients in remission with persistent T-cell clones. In all cases,

clonal products, which were originally identified in the BM and PB were shown to belong to the CD8+ population of cells (Fig.). In one case BM and PB derived-CD4+ cells also shared a clonal product with LN cells tested at at the diagnosis. In one case CD4+ population selected from PB cells at the diagnosis carried clonal rearrangements, fully consistent with that of LN.
Summary/Conclusions: One may conclude that CD8+ T-cell clones identified in BM and PB, do not match those identified in LN for the majority of patients with AITL (76%). These clones can persist for a long time (the period of observation from 1 to 40 months), may not disappear in remission and probably have reactive nature. Therefore exclusive T-cell clonality in PB and/or BM should not be threated as minimal disease or relapse in AITL.

E1404

CD5 POSITIVE DIFFUSE LARGE B CELL LYMPHOMA SHOWED FREQUENT MYC EXPRESSION AND AGGRESSIVE CLINICAL BEHAVIOR
H.-Y. Na[1], J.Y. Choe[2], H.-J. Kim[3], J.H. Han[4], H.K. Kim[5], G. Park[6], H.J. Cha[7], J.E. Kim[8,*]
[1]Pathology, Seoul National University Hospital, Seoul, [2]Pathology, Hallym University Sacred Heart Hospital, Anyang, [3]Pathology, Sanggye Paik Hospital, Inje University college of medicine, Seoul, [4]Pathology, Ajou University School of Medicine, Suwon, [5]Pathology, Soonchunhyang University Hospital, Pucheon, [6]Pathology, Seoul St. Mary's Hospital, Seoul, [7]Pathology, Ulsan University Hospital, Ulsan, [8]Pathology, Seoul National University Boramae Hospital, Seoul, Korea, Republic Of

Background: Aberrant expression of CD5 distinguishes a unique immunohistochemical subtype of diffuse large B cell lymphoma (DLBCL). This CD5+ DLBCLs, either *de novo* lesions or transformed from preceding low grade lymphomas, are characterized by unique molecular pathologic alterations and aggressive behavior. The incidence of CD5+ DLBCL was variably reported from 5 - 22% of all DLBCLs in western countries and Japan, however, no exact data available in Koreans.
Aims: This study aimed to investigate clinicopathologic features of CD5 + DLBCL among Koreans.
Methods: A total of 350 cases of DLBCL were reviewed 4 university hospitals from 2004 to 2012. Review of the histologic features along with immunohistochemical study for BCL1, BCL2, BCL6, CD5, CD10, CD23, CD30, IRF4/MUM1, MYC, Ki-67 and EBV *in situ* hybridization was performed. Florescent *in situ* hybridization (FISH) for MYC rearrangement and amplification was also performed. The results were compared with DLBCL-NOS (N=195).
Results: Thirty cases of CD5+ DLBCL were retrieved among 350 cases of DLBCL (8.6%), which showed predominance of female (20/30), elderly (mean age 64), and extranodal presentation (16/30). Richter transformation was suspicious in only one case, and EBV was negative in all. Most cases (22/30) belong to non-GCB subtype by Hans classifier. Rearrangement of MYC was found in 2 cases and amplification was found in one. Compared with DLBCL-NOS, CD5+ cases revealed significantly higher expression of MYC, BCL6, IRF4/MUM1 and Ki67 (all p<0.05). Double expression of both BCL2 and MYC was found in 9 of 30 cases (30%). Also, CD5+ DLBCL showed more frequent bone marrow involvement, advanced stages and high international prognostic index (all p<0.05). In univariable survival analysis, CD5+ DLBCL revealed significantly shorter progression free survival (median 8.2 months) compared with DLBCL-NOS (median 56.3 months) (p<0.05)
Summary/Conclusions: This is the first collective study of CD5+ DLBCL in Korea. The incidence, clinical presentation, and pathologic features including cell of origin coincide with previous reports from western population or Japanese. However, frequent high expression of MYC without chromosomal structural alteration was a unique finding in our study. Expression of CD5 should be routinely investigated in DLBCL to find this particularly aggressive subtype.

E1405

REACTIVE FLORID B-LINEAGE LYMPHOID PROLIFERATIONS IN HIV INFECTION MAY MIMIC LYMPHOMA
T. Wiggill[1,*], J. Vaughan[1], E. Mayne[1]
[1]Molecular Medicine and Haematology, National Health Laboratory Service and University of the Witwatersrand, Johannesburg, South Africa

Background: Approximately 7 million people are living with Human Immunodeficiency Virus (HIV) infection in South Africa (SA) (2015), which is associated with an increased risk of lymphoma. Although there is limited local information available, previously published data from the Johannesburg academic complex of hospitals (SA) showed an HIV prevalence of >90% in patients diagnosed with high grade B cell non Hodgkin lymphoma (NHL) who were tested for HIV (n= 568), during the period 2007-2009. The diagnosis of lymphoma with comorbid HIV infection is, however, challenging as lymphomas may present with atypical features and in unusual extranodal sites. In addition, there are reactive conditions which may mimic lymphoma (such as Tuberculosis (TB)). Within this setting reactive florid B-lineage lymphoid proliferations (RBLP) in the blood and bone marrow may raise a differential diagnosis of lymphoma.
Aims: This study aims to document the clinico-pathological features of florid RBLP in the setting of HIV infection in order to provide an approach to differentiating reactive and clonal processes.
Methods: A retrospective database search was performed of the laboratory information system (National Health Laboratory Service) that screened pathology reports for samples referred to the Departments of Molecular Medicine and Haematology and Anatomical Pathology at the Johannesburg Academic Complex during 2007-2011, supplemented with results of immunophenotypic analysis from 2007-2016. Demographic and clinico-pathological findings were collected for patients identified with florid RBLP who showed no definite evidence of monoclonality.
Results: During this period, 38 patients were diagnosed with florid RBLP with up to 70–80% of cells in blood or bone marrow comprising reactive B cells (including mature B, plasmablasts and plasma cells). All patients tested were HIV positive, with a median age of 28 years (range 6 months-79 years). There was a bimodal age pattern with a peak in children <1 year of age (34% of patients). This is different from the pattern noted in NHL in our centre, where lymphoma is virtually absent in children under a year of age. Common clinical presentations included cytopenias (85%); infection (70%) (commonly Cytomegalovirus (35%), TB (30%) and bacterial septicaemia (22%)); hepatosplenomegaly (42%); and lymphadenopathy (36%). Patients showed increases in serum total protein levels (reflecting hypergammaglobulinaemia), with increased inflammatory markers (C-reactive protein and erythrocyte sedimentation rate) and evidence of increased cell turnover (high uric acid, B2 microglobulin and lactate dehydrogenase levels). Extremely high HIV viral loads (VL) were documented (median 1 612 003copies/ml, range 12 000 - 10 000 000). Only one patient was virologically supressed. This is significantly different from lymphoma patients where median VL ranged from 16 000- 97 000 dependent on subtype. Median CD4 counts were also higher in this subgroup of patients when compared to patients with lymphoma (see table 1). Limited follow-up data was available, with only 8 patients documented to be attending an HIV clinic for long-term follow-up.

Table 1. Comparative data: HIV associated lymphoma and HIV associated RBLP.

	RBLP	Diffuse large B cell lymphoma	Burkitt lymphoma	Hodgkin lymphoma
Age years Median (range)	28[1] (0,5– 79) [n=38]	40[123] (5-88) [n=639]	33[2] (2-65) [n=149]	33[3] (4-84) [n=263]
Viral load copies/ml Median (Range)	1 612 003[123] (12 000 - 10 000 000) [n=20]	72 000[1] (27 – 4 800 000) [n=202]	97 000[2] (130 – 3 000 000) [n=60]	16 000[3] (38 – 2 500 000) [n=52]
CD4 count cells/uL Median (Range)	275 (14-2509) [n=16]	109[1] (3-960) [n=400]	176[1] (2-960) [n=129]	125 [n=52]

123p-value<0.001, Children excluded from CD4 count analysis.

Summary/Conclusions: In the setting of HIV, reactive conditions may mimic lymphoma and vigilance is needed in the confirmation of monoclonality. Patients with RBLP presented at a younger age when compared to their counterparts with lymphoma. They had extremely high VL with higher CD4 counts, suggesting this may be a feature of early HIV disease and the possibility of a seroconversion type illness should be considered.

E1406

MICROVESSEL DENSITY IN CD30 POSITIVE DIFFUSE LARGE B-CELL LYMPHOMAS
F. Gaudio[1,*], G. Ingravallo[2], T. Perrone[1], P. Sindaco[1], V. Carluccio[1], S. D'agostino[1], M. Di Noi[1], F.E. Laddaga[1], R. Tamma[3], S. Ruggieri[3], P. Pedote[4], G. Specchia[1]
[1]Hematology, [2]Pathology, [3]Human Anatomy and Histology, [4]Radiology, Bari, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common and one of the most heterogeneous lymphomas. Therefore, it is critical to further stratify cases of DLBCL into biologically similar and clinically meaningful subgroups, which will not only guide prognostic assessment and facilitate therapeutic decisions but also stimulate further research to understand the pathogenesis and develop novel potential treatments. Preliminary reports involving a number of different kinds of tumors have indicated that microvessel quantification may be useful in predicting disease outcome.
Aims: The aim of this study was to examine the relationship between microvessel density (MVD) as a parameter of tumor angiogenesis, and the immunophenotype in patients with diffuse large B-cell (DLBC) lymphomas.
Methods: We retrospectively identified cases of DLBCL diagnosed between January 2010 and January 2016 at our Institution. The following large B cell lymphoma subtypes were excluded from this analysis: post-transplant lymphoproliferative disorders with a DLBCL morphology, Primary Mediastinal large cell lymphoma and unclassifiable lymphomas with intermediate features between either DLBCL and Burkitt's lymphoma or DLBCL and Hodgkin's lymphoma. Immunohistochemistry was performed as part of the routine workup and CD30 was considered positive at ≥30% staining of neoplastic cells.

Microvessel quantification was performed by immunohistochemical staining, using monoclonal antibodies against platelet/endothelial cell adhesion molecule-CD31. A total of 82 cases of *de novo* DLBCL treated with R-CHOP were included in the training set for further analysis There were 45 men and 37 women, with a median age of 57 years (range, 16-84); 35 patients (43%) presented with B symptoms, and 49 (60%) had advanced Ann Arbor stages. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0- 1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0-2, 63%). Involvement of multiple extranodal sites (>=2) was seen in 22% of cases, and bulky disease in 32% of cases.
Results: The median follow-up time was 47 months. Among the 82 cases in the training set, CD30 was positive in 24 cases (29%). No difference in response rate was observed between CD30 positive and CD30 negative patients. Patients with CD30+ DLBCL showed a significantly superior OS and PFS compared with CD30– patients. The 5-year OS was 79% in patients with CD30+ *vs* 59% in CD30– (P<0.05); 5-year PFS was 82% in patients with CD30+ *vs* 63% in CD30– (P<0.05). In patients with CD30 positive diffuse large B cell lymphomas we found a smaller number of vessels compared with patients CD30 negative (fig.1, p<0.05).

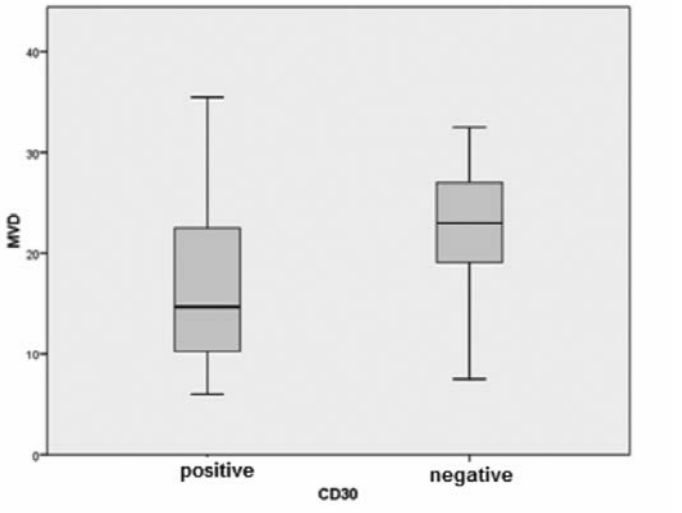

Figure 1.

Summary/Conclusions: CD30 is expressed in approximately 29% of all DLBCL and defines a novel subgroup of diffuse large B-cell lymphoma with a more favorable prognosis. Microvessel density expression is lower in CD30 positive DLBCL. The advent of brentuximab vedotin and its well-established effectiveness in other types of relapsed lymphomas has introduced the possibility of its application in this subset of patients.

E1407

ANTIGEN SELECTION PROMOTES CLONAL CYTOTOXIC T-CELL RESPONSES: HIGH-THROUGHPUT IMMUNOGENETIC EVIDENCE

E. Stalika[1,*], C. Galigalidou[1], A. Papalexandri[2], A. Vardi[2], N. Stavroyianni[2], I. Batsis[2], I. Sakellari[2], A. Anagnostopoulos[2], N. Maglaveras[3], I. Chouvarda[3], M. Papaioannou[4], K. Stamatopoulos[1], A. Hadzidimitriou[1]
[1]Institute of Applied Biosciences, Centre for Research and Technology Hellas, [2]Hematology Department and HCT Unit,G. Papanicolaou Hospital, [3]Laboratory of Computing and Medical Informatics, [4]First Department of Medicine, Medical School, Thessaloniki, Greece

Background: Expansions of T-large granular lymphocytes (T-LGL) with a characteristic $CD3^+CD8^+CD57^+$ phenotype may be either idiopathic or develop in the clinical context of several conditions *e.g.* autoimmunity, viral infections, post-transplant and in hematologic malignancies. Whether this heterogeneity reflects a dynamic process of cytotoxic T-cell responses against auto- and exo-antigens remains to be established. That said, earlier, low-throughput immunogenetic studies have implicated antigenic drive in the development of T-LGL lymphoproliferations. However, due to the inherent limitations of low-throughput analysis, definitive conclusions were not possible.
Aims: To obtain comprehensive insights into the role of antigen selection in the pathogenesis of T-LGL lymphoproliferations using next-generation sequencing (NGS) for in-depth immunoprofiling of the clonotypic T cell receptor beta chain (TRBV) genes.
Methods: Included in the study were (i) a father and a son with T-LGL leukemia, the first case of intra-family occurrence; a single blood sample from the father and 2 samples from the son spanning 5 years were analyzed; and, (ii) a patient with T-LGL leukemia of donor cell origin developing after allogeneic hematopoietic cell transplantation (allo-HCT) for Philadelphia-positive acute lymphoblastic leukemia: for this case, the donor blood was analyzed as were two blood samples, one at the first documentation of clonal T-LGL expansion (at 6 months post allo-HCT while investigating persistent neutropenia that developed after Rituximab treatment for EBV reactivation) and a second 3 years later; at both timepoints, the patient had 100% donor chimerism and tested negative for *BCR-ABL* transcripts. TRBV-TRBJ-TRBD rearrangements were amplified on gDNA and subjected to paired end NGS, covering the CDR3 twice/sequence. To increase the consistency of results, raw NGS reads were analyzed by a purpose-built bioinformatics algorithm, performing: (i) quality filtering, (ii) merging of filtered in paired reads and (iii) quality filter of stitched sequences. Filtered-in sequences were submitted to IMGT/HighV-QUEST, and metadata was processed by an in-house dedicated bioinformatics pipeline.
Results: Only productive TRBV-TRBD-TRBJ rearrangements were included in the analysis. Overall, 1,129,289 filtered-in sequences from 6 samples were evaluated (median 188,095 sequences/sample). Major findings in the familial cases included: (i) pronounced skewing of the TRBV repertoire; (ii) existence of more than one immunodominant clonotype; (iii) in the analysis of longitudinal samples from the son, persisting clonotypes albeit with fluctuating frequencies (clonal drift); and, (iv) shared ('public') clonotypes between father and son. In the T-LGL leukemia of donor origin, the immunodominant clonotype was detected amongst the polyclonal donor repertoire and subsequently expanded in the recipient, persisting over time and accompanied by a few other considerably expanded, albeit smaller, clonotypes.
Summary/Conclusions: The borders between polyclonal *versus* oligoclonal *versus* monoclonal T-LGL lymphoproliferations are not sharply demarcated, but rather the transition from a polyclonal cytotoxic response to the development of T-LGL leukemia is a gradual process. Repertoire restrictions, public clonotypes and clonal drift strongly indicate selection by restricted (perhaps also shared) antigens in T-LGL leukemia ontogeny and evolution.

Orsola-Malpighi Hospital, University of Bologna, Bologna, [6]Department of Molecular Medicine, Hematology, Sapienza University, Rome, [7]Division of Hematology, Azienda Ospedaliera SS Antonio e Biagio e Cesare Arrigo, Alessandria, Italy

Background: In B-cell non-Hodgkin lymphomas, minimal residual disease (MRD) is a highly valuable tool for the direct assessment of the reduction of the disease burden. In 2009, the four laboratories of the Fondazione Italiana Linfomi (FIL) - FIL MRD network - started a collaborative effort to harmonize and standardize their methodologies, performing QC (Quality Control) rounds twice a year for follicular lymphoma (FL) and mantle cell lymphoma (MCL) MRD assessment.
Aims: We evaluated the molecular results of bone marrow (BM) samples analysis performed during the QC rounds, to determine how borderline samples (*i.e.* those with a low MRD level) challenge the inter-lab reproducibility and data interpretation.
Methods: Between February 2010 and November 2016, in the context of 14 QC rounds, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples; 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). *BCL2/IGH* MBR rearrangement was analyzed by nested PCR (Gribben, 1993) and by RQ-PCR (Ladetto, 2000). Clonality assessment was performed using an IGHV multiplex consensus PCR (Van Dongen, 2003) and RQ-PCR was carried out as described (Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the "EuroMRD Consortium" guidelines (van der Velden, 2007).
Results: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10^{-5} and a quantitative range for RQ-PCR of at least 10^{-4}. Ninety-three/114 FL BM samples showed a 81% concordance (75/93) being PCR+/RQ-PCR+ or PCR-/RQ-PCR- in all the 4 labs. The remaining 18/93 (19%) were alternatively positive and negative in the inter-lab evaluations, representing samples with very low MRD levels, thus defined as "borderline" (brd): 6/18 were PCR-brd/RQ-brd, 6/18 were PCR-brd/RQ-positive not quantifiable (PNQ) and 6/18 were PCR-/RQ-brd. Among the 74 MCL BM samples, the concordance rate was 86% (64/74; +/+ or -/-). Ten/74 resulted brd samples: 1 was PCR-negative/RQ-brd, 5 were PCR-brd/RQ-brd, 2 were PCR-brd/RQ-PNQ and 2 were PCR-brd/RQ-negative. Overall, considering the 167

samples analyzed by both methods, 83% (139/167) of these were classified as +/+ or -/- by all the FIL labs. The remaining 28/167 (17%) were the samples that showed discordant results in the inter-lab assessments: while in 17 cases the "borderline status" was defined alternatively by only one method, 11 resulted brd samples by both techniques (11/167, 6.6%) (Fig.). Given that the 167 samples were tested in three replicates across the 4 labs, a total of 12 replicates/sample were analyzed: 31 brd samples were thus identified, 13 of which brd by both approaches. Of 156 evaluations performed on the 13 brd, 69/156 (44%) resulted PCR-positive and 87/156 (56%) PCR-negative, 58/156 (37%) were RQ-PNQ and 98/156 (63%) RQ-negative.

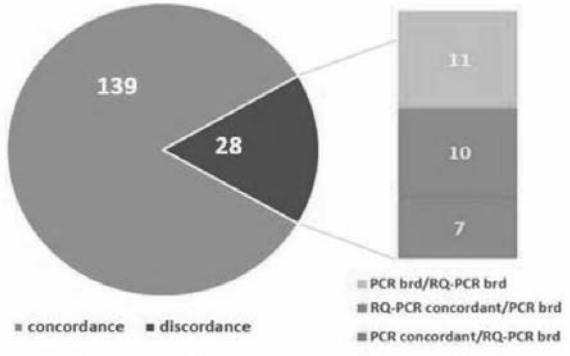

Figure. 167 BM samples analyzed by PCR and RQ-PCR. 139/167 samples were classified as positive or negative by all the FIL laboratories with both methods, while 28/167 showed discordant results in the inter-lab assessments. Among the 28 borderline (brd) samples, 21 resulted PCR-brd and 18 RQ-PCR-brd. In particular, 10 were concordant for RQ-PCR and brd for PCR, 7 resulted concordant for PCR and brd for RQ-PCR, 11 were classified as brd samples by both techniques.

Figure 1.

Summary/Conclusions: Despite the high inter-lab reproducibility in the MRD analysis that can be obtained and maintained by the QC round strategy, samples with the lowest MRD levels can still represent a challenge: 17% (28/167) of our series resulted brd, showing discordant results in inter-lab assessments; 39% of them (11/28) remained brd even applying both methods. The results did not change even increasing the number of replicates/sample. Thus, although representing a minority, brd samples are still problematic, especially when a clinically oriented interpretation is required. As the combined use of standard methods does not totally solve this problem, alternative, novel, methods such as digital PCR and NGS need to be tested in this context.

E1409

RHOA GLY17VAL MUTATION AND T-CELL CLONALITY ANALYSIS IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

Y. Sidorova[1,*], N. Chernova[2], I. Yakutik[1], S. Smirnova[1], N. Ryzhikova[1], E. Nikulina[1], M. Aleksenko[2], O. Glinshchikova[1], M. Sinitsyna[3], A. Kovrigina[3], E. Zvonkov[2], A. Sudarikov[1]

[1]Department of Molecular Hematology, [2]Department of Lymphoma Chemotherapy, [3]Department of Pathology, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare subtype of T-cell lymphoma, characterized by generalized lymphadenopathy, hyperglobulinemia, and autoimmune manifestations. Interpretation of histological and immunohistochemical data can be difficult due to the small number of tumor CD4+ T cells, surrounded by abundant polymorphocellular infiltrate. AITL could often be misdiagnosed as reactive processes and other lymphomas, including Hodgkin's lymphoma. T cell clonality assessment plays an important role in AITL diagnosis. However, ambiguous clonality results may be obtained. Recently discovered somatic RHOA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas. We compared the efficacy of T-cell clonality testing and quantitative allele-specific PCR RHOA Gly17Val mutation assay in different tissues for AITL diagnosis.
Aims: To correlate the number of RHOA Gly17Val mutated cells in lymph nodes, blood, bone marrow and skin of AITL patients with corresponding T cell clonality results.
Methods: Lymph nodes (LN), skin biopsies, blood and bone marrow (BM) samples were studied for 40 patients with AITL. The male/female ratio was 25/15, median age was 65 years (36-92). To evaluate T-cell clonality rearranged TCRG and TCRB gene rearrangements were PCR-amplified according to BIOMED-2 standardized protocol and analyzed by capillary electrophoresis on ABI PRISM 3130 (Applied Biosystems). Sensitivity of T-cell clonality assay was limited to 10% of clonal T-cells of the total T-lymphocytes in the sample. Gly17Val mutation was analyzed by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay. The detection level of this method was 1% of mutated cells in the total cell population.
Results: The clonal TCR gene rearrangements in LN were found in 37 of 40 patients (92%). RHOA (Gly17Val) mutation in LN was revealed in 60% (24 of 40) patients. T-cell clonality was detected in 26 of 28 primary samples of BM, but in 12 of 26 patients (46%) clonal TCR rearrangements were not matched in length with rearrangements detectable in LN. Number of cells with RHOA mutation was highest in the LN (in average 26.7% of the total cells), while in the bone marrow RHOA mutation was undetectable (in 7 patients), or detected in 10 patients in a small amount (in average 2% of the total cells). Combined histological investigation, T-cell clonality and RHOA (Gly17Val) testing showed BM lesion in 76% of patients (13 of 17) with at least one of the methods. Blood and bone marrow samples examined simultaneously showed slightly higher numbers of RHOA positive cells in the blood than in the BM in 5 of the 7 RHOA positive patients. Significant percentage of cells with a RHOA mutation (in average 25% of the total cells) was revealed in 5 of 6 skin samples from RHOA positive patients. We have found good correlation (Spearman's Rho-0,8198, p-level <0,00001) between T-cell clonality (matching with LN clonal peaks) and the number of RHOA positive cells in the AITL samples (n 51). Skin, blood and bone marrow samples with the T cell clonality peaks that differ from those found in the LN were also negative for the presence of cells with RHOA (Gly17Val) mutation.
Summary/Conclusions: RHOA (Gly17Val) point mutation is detected in LN by allele-specific PCR in 60% of patients with AITL. The percentage of tumor cells in BM is low (averaging less than 2% of the total cells). However, combined molecular and histological data suggest that BM may be involved in most patients. Extent of T cell clonality (matching with LN clonal peaks) correlates with the amount of cells having a RHOA mutation. T-cell clonality in BM, skin, spleen, etc. with rearrangements not matching those identified for the LN should be considered reactive and possibly associated with autoimmune process or antiviral response.

Other Non-malignant hematopoietic disorders

E1410

USEFULNESS OF CHITOTRIOSIDASE ACTIVITY, CCL18/PARC, 7-KETOCHOLESTEROL AND GLUCOSYLSPHINGOSINE CONCENTRATIONS FOR SCREENING OF LYSOSOMAL STORAGE DISORDERS

P. Irún[1,2,*], J.J. Cebolla[1,2,3], L. Lopez de Frutos[2,4], P. Giraldo[1,2,4]
[1]Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBERER), [2]Unidad Investigación Traslacional. Hospital Universitario Miguel Servet, Instituto de Investigación Sanitaria Aragón (IIS Aragón), [3]Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, [4]Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomales (FEETEG), Zaragoza, Spain

Background: Gaucher (GD), Niemann-Pick Type A/B (NPA/B), Niemann-Pick Type C (NP-C) and the Lysosomal acid lipase deficiency (LALD) are lysosomal storage diseases (LSDs) difficult to diagnose due to the great heterogeneity of signs and symptoms, including haematological disorders, sometimes common to several pathologies, and the consequent alteration of biomarkers.
Aims: To assess the diagnostic utility of Chitotriosidase activity (ChT), CCL18/PARC, 7-ketocholesterol (7KC) and glucosylsphingosine (Lyso-Gb1) concentrations in previously mentioned LSDs.
Methods: ChT activity, CCL18/PARC and 7KC concentrations were measured in 146 plasma samples from subjects with suspected LSD (32 GD, 7 NPA/B, 90 NP-C and 17 LALD) received in our laboratory. In addition, a new biomarker, the Lyso-Gb1 concentration, was evaluated in 83/146 of previous mentioned subjects, 19 of them with confirmed LSD diagnosis. ChT was evaluated using a fluorogenic substrate, CCL18/PARC concentration by ELISA and 7KC and Lyso-Gb1 by liquid chromatography followed by tandem mass spectrometry.
Results: A total of 9/32 (28%) samples with suspected GD showed high ChT and/or high CCL18/PARC, 4/9 confirmed GD status; the rest were 1 NPA/B, 1 NP-C and two carriers of NP-C. Only 3/7 (43%) with suspected NPA/B and altered biomarkers were confirmed. Among the 23/90 (26%) with suspected NP-C and some elevated biomarker four were diagnosed of NP-C, and two carriers showed some biomarker higher than cutoff. Of the 8/17 (47%) referred to LALD suspicion with some elevated biomarker six were affected. All GD confirmed patients show high levels of Lyso-Gb1 whereas none of the other cases showed elevation for mentioned biomarker.
Summary/Conclusions: The screening of three biomarkers: ChT activity, CCL18/PARC and 7-ketocholesterol concentrations (the latter not applicable in GD) is a powerful tool to identify patients at high risk of suffering from LSDs which should undergo confirmatory diagnostic tests. In this line we would have reduced the number of cases needing confirmatory diagnostic test from 146 to 43 (29%) and 19/43 (44%) were positive for LSDs. Lyso-Gb1 concentration can allow the unambiguous identification of all the GD patients but is not useful for the other LSDs.

E1411

THE VALUE OF SOLUBLE IL-2R APLHA SUBUNIT MEASUREMENT IN CSF OF CHILDREN WITH HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH): PRELIMINARY OBSERVATIONS

Y. El Chazli[1,*], A. Elsharkawy[1], N. Mikhael[2], M. Abd El-Maksoud[3], W. Shoman[4], H. Assem[1]
[1]Department of Pediatrics, Hematology/Oncology unit, [2]Department of Clinical pathology, [3]Department of Pediatrics, Neurology unit, [4]Department of Pediatrics, Immunology/Rheumatology unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening clinical syndrome due to a severe hyperinflammatory response. HLH is typically divided into a primary, genetic form and a secondary, acquired form. It is characterized by a very wide spectrum of clinical findings. Central nervous system affection "CNS disease" has been frequently described at presentation of HLH, during course of disease, or as isolated CNS-HLH that could preceed other systemic clinical manifestations by months to years.
Aims: To study the value of CSF soluble interleukin-2 receptor alpha subunit (sIL-2Rα) assay as a marker of CNS affection in children with HLH.
Methods: In this descriptive, observational study done at Alexandria University Children's Hospital, we analyzed the clinical data of a group of patients diagnosed as HLH. After informed consent was obtained, data was collected from patients who have undergone clinical examination, brain MRI, routine CSF analysis for evaluation of CNS-HLH, and sIL2Rα measurement in the CSF (Quantikine Human CD25/IL-2Rα Immunoassay, R&D Systems). Patients were considered as "CNS-HLH positive" when they had either neurological manifestations, abnormal findings on MRI or routine CSF analysis (elevated proteins &/or pleocytosis) and as "CNS-HLH negative" when they did not show any of these findings.
Results: We analyzed the data of 9 HLH patients; 4 females and 5 males. Their age ranged from 2 months to 13 years with a median of 5 months. Six patients had genetic diseases predisposing to HLH [Griscelli syndrome type II (GSII) & Chediack-Higashi syndrome (CHS)], and 3 other patients were diagnosed according to HLH-2004 diagnostic criteria and presumed to be of familial form (FHL). Out of the 9 patients, only 5 patients (55.6%) showed clinically evident neurological manifestations; 5 patients (55.6%) had elevated CSF proteins &/or pleocytosis, and 4 patients (44.4%) had an abnormal brain MRI. Overall 7 out of the 9 patients (77.8%) were "CNS-HLH positive" *versus* only 2 (22.2%) "CNS-HLH negative" according to classical criteria. Interestingly, the geometric mean of CSF sIL2Rα in CNS-HLH positive group was lower than in CNS-HLH negative group (734 *vs* 1952 pg/ml, p= 0.094). Moreover, CSF protein level and cell counts did not statistically correlate with CSF sIL2Rα level. Several patients showed interesting observations. Among the 3 patients with presumed FHL (6/7 HLH-2004 diagnostic criteria fulfilled, NK cell activity not tested), the one with the highest observed CSF sIL2Rα level (17329 pg/ml), a 2 months old infant, was "CNS-HLH negative", but had severe bilateral papilledema (discovered during workup for suspected autoinflammatory disorder). The second patient was a 3.5 year old boy, with history of a year of "CNS-HLH positive" findings and psychomotor regression, he had severe papilledema associated with high CSF sIL2Rα (3700 pg/ml). The third patient, an 11 months old "CNS-HLH negative" infant also had a relatively elevated CSF sIL2Rα of 220 pg/ml. On the other hand, 2 twin sisters evaluated at the age of 3 months for HLH secondary to CHS (positive family history, grey hair), had no systemic, neurological or radiological evidence of HLH, but had positive routine CSF analysis (elevated protein & pleocytosis) and CSF sIL2Rα (600 & 800 pg/ml).
Summary/Conclusions: We hypothesize that routine CSF sIL2Rα level assay could enhance earlier & better detection of CNS-HLH in children especially in primary and genetic forms. Moreover, the absence of statistically significant correlation between serum and CSF levels of sIL2Rα in our patients indicates that sIL2Rα is locally produced in the CSF secondary to cellular infiltration of the CNS and could be a valuable biological marker of disease activity. Larger prospective studies are warranted to confirm these results and determine diagnostic and prognostic value of CSF sIL2Rα levels, as well as its value for follow up of CNS disease.

E1412

GAUCHER DISEASE PATIENTS EXHIBIT A HIGH EXPRESSION OF LIPOCALINE (LCN2) AS POSSIBLE BIOMARKER OF RESIDUAL DISEASE ACTIVITY. EXPLORATORY STUDY AND CORRELATION WITH OTHER CYTOKINES

M. Andrade-Campos[1,*], M.P. Garcia Sobreviela[2,3], B. Medrano Engay[3], P. Irun[1], J. Gervas Arruga[3], M. Arbones[2,3], P. Giraldo[1,4]
[1]Translational Research Unit, IIS-Aragon. CIBERER. IISCIII, [2]ADIPOFAT, Instituto Aragones de Ciencias de la Salud, [3]Translational Research Unit, IIS-Aragon., [4]FEETEG, Fundacion Española Estudio y Terapeutica Enfermedad de Gaucher, Zaragoza, Spain

Background: Gaucher Disease (GD) is characterized by a latent chronic inflammatory macrophage activation status expressed by an imbalance on pro-inflammatory cytokines, hyperferritinemia, hypergammaglobulinemia, altered calcium homeostasis and metabolic syndrome. Even patients under ERT do not fully revert this status and their risk to develop bone crisis, iron metabolism alterations, autoimmune disorders and neoplasm remain higher. This observation leaded to the creation of the minimal-residual-disease-activity concept. Monitorization of patients through chitotriosidase and CCL18/PARC has become essential however there are patients whom never normalize while others developed bone crisis/ complications after long-time under therapy and normal values. One of the key features for chronic inflammation is the anemia; this is characterized by hyperferritinemia a common feature at diagnosis of GD1 patients. Lipocaline (LCN2), a cytokine released by adipocytes, mononuclear cells and neutrophils with expression on endothelial cells, hepatocytes and other cells, has been involved into the monocyte polarization and perpetuation of the inflammatory state. Based on this, we have performed an exploratory study assessing LCN2 expression in GD1 patients.
Aims: To explore the Lipocaline (LCN2) expression as biomarker for disease activity in type 1 Gaucher Disease patients under different circumstances.
Methods: We have performed an exploratory study on 18 GD1 patients distributed in two cohorts. Cohort A was composed by 6 patients: 2 naïve (N) cases and 4 under miglustat (M) therapy; this patients were part of the clinical study QUELAFER and sere from baseline and after 4 months on chelation therapy were obtained. Cohort B included 12 patients on enzymatic replacement therapy (ERT), for this cohort sera samples were obtained for LCN2 determination and also a panel of cytokines (IL-10, IL-13, IL-4, IL-6, IL-7, Mip1a, Mip1b y TNFa), ferritin, hepcidin, chitotriosidase and CCL18/PARC were analyzed at beginning of ERT and after one year on it. Data were incorporated into a database for this porpoise including demographic and clinical available data. All patients have signed an inform consent for the use of their samples and ethical approved were obtained form institutional board of FEETEG foundation.
Results: Compared to reference controls provided by the manufacturer, all the patients showed increased levels of serum LCN2, the overall mean value for the initial sample was 171, 88 (66,72-261,72). As cohorts the differences among individuals were significant (Cohort A, p=0.02 and cohort B, p<0.01). Naïve

patients exhibit the higher values. In general 9 patients showed a reduction on LCN2 levels while 7 showed an increase and one the value was stable. All patients showed a reduction in ferritin and chitotriosidase, however a fully correlation with LCN2 expression were not founded. Globally there were no statistically differences, but as individual T-test showed a difference between both measures (p=0.027). A detailed description an analysis will be presented in case of acceptance.
Summary/Conclusions: Lipocaline expression is increased in GD1 patients in general, a correlation with other cytokines expression to establish the role of this biomarker is warranted.

E1413

COMPARISON OF TREATMENT AND OUTCOMES BETWEEN ACQUIRED PRIMARY AND SECONDARY THROMBOTIC THROMBOCYTOPENIC PURPURA
S.H. Wai[1,2,*], H.J. Ng[2], T.C. Wen[2], J. Quek[2], H.T. Mya[2]
[1]Monash University, Melbourne, Australia, [2]Singapore General Hospital, Singapore, Singapore

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare disease that is fatal if untreated. While the main treatment modality is plasmapheresis, immunosuppressants also play a crucial role in the treatment of TTP.
Aims: Our aim is to compare the clinical characteristics, treatment and outcomes of patients with acquired primary TTP to those with secondary TTP *i.e.* autoimmune and malignancy/ hematopoietic stem cell transplant (HSCT) related.
Methods: We reviewed all patients with TTP who received plasmapheresis at our institution from 1st Jan 2008 to 31st Jan 2017. Clinical and laboratory characteristics, treatment, response to treatment and complications were recorded. Complete remission (CR) was defined as platelet count normalisation, partial remission (PR) as platelet count doubling and >30 x 10^9/L and the rest as unresponsive/mortality (UM).
Results: Of 41 cases of TTP, 24% (n=10) was primary, 44% (n=18) was secondary to autoimmune diseases, 27% (n=11) was secondary to malignancy or HSCT, 5% (n=2) was related to DRESS syndrome and acute pancreatitis. The median age was 47(18-86) years and it was predominately female (81%). About two-thirds of the cases presented with neurological symptoms (66%), renal dysfunction (56%) and fever (59%). Only 12 patients (29%) had TTP pentad. Proportionate to incidence of secondary TTP, 85% required immunosuppressive therapy. CR was seen in 51% (n=21) and PR in 15% (n=6). Mortality rate at end of treatment was 41% (n=17) and at end of follow-up was 46% (n=19). Comparison of demographics, clinical presentation, treatment and outcomes between acquired primary TTP and secondary TTP are shown in table below.

Table 1.

		Primary TTP (n=10)	Autoimmune diseases related TTP (n=18)[£]		Malignancy/ HSCT related TTP (n=11)[#]	
Age (median, range)		57 (30–86)	41 (20–61)**		41 (18–84)	
Female (%)		80	83		82	
Neurological symptoms (%)		90	72		36**	
Renal dysfunction (%)		30	72*		46*	
Fever (%)		60	72		27	
Plasmapheresis session (median, range)		12.5 (8–34)	11 (4–128)		9 (2–45)*	
Rituximab (%)		30	72*		NA	
Vincristine (%)		20	17		NA	
Cytotoxic medications (%)		0	50**		NA	
Immunomodulators (%)		0	67**		NA	
Renal replacement therapy (%)		0	39**		46**	
Nosocomial infections (%)		30	78**		64	
Thrombosis (%)		40	22		9*	
Major Haemorrhage (%)		20	44		36	
Days of hospitalization (median, range)		21.5 (10–50)	48.5 (9–203)**		37 (7–100)	
D7	CR (%)	60	17	**	0	**
	PR (%)	20	22		55	
	UM (%)	20	61		46	
At completion of treatment	CR/PR (%)	80	61		55	
	Mortality (%)	30	50		46	
Relapse (%)		14	38		17	
Follow-up duration in months (median, range)		12.2 (0.3–111.3)	13.7 (0.2–128) 50		4.8 (0.3–86.6) 55	
Mortality at end of follow-up (%)		40	40 (5–193)		15 (1–144)	
Days to mortality (median, range)		15 (10–23)				

*Compared to primary TTP using chi-squared for categorial data and non-parametric Mann-Whitney U Test for continuous data. * P<0.1 **P<0.05.*

Summary/Conclusions: Compared to primary TTP, secondary TTP had an initial poorer response to plasmapheresis. Patients with autoimmune diseases required more immunosuppressive therapy and rituximab. Although the final response and mortality rates showed a trend towards poorer prognosis in secondary TTP, it was not statistically significant. Further studies are needed to improve the treatment of TTP, both primary and secondary.

E1414

EVANS SYNDROME IN CHILDHOOD: LONG TERM SINGLE CENTER EXPERIENCE
A. Teli[1], E. Farmaki[1], A. Taparkou[1], D. Adamidou[2], M. Economou[1,*]
[1]Aristotle Universtity of Thessaloniki, [2]Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Evan syndrome (ES) is a rare entity in childhood, usually presenting with a course that is chronic and refractory to treatment.
Aims: To report on the clinical and laboratory characteristics of pediatric patients with ES diagnosed and long followed at a single center.
Methods: Data covering a 15 year period and concerning 14 ES patients were retrospectively studied. Clinical presentation, laboratory parameters, diseased severity, therapeutic approaches, number of relapses, presence of complications, time of follow-up and final outcome were reported. Disease was considered active when Hb <7g/dl and/or PLT <30,000/mm^3 and/or N<500/mm^3, in partial remission (PR) when 7-11g/dl and/or PLT 30,000 – 10,0000/mm^3 and/or N 500 – 1,000/mm^3, in short-term complete remission (SCR) when >11g/dl and PLT >100,000/mm^3 and N >1,000/mm^3 when still under or less than 12 months off treatment, and in long-term complete remission (LCR) when laboratory values as in SCR but free of treatment for over 12 months.
Results: Mean age at diagnosis was 5.4 years (18 months-12 years). Recent history of infection was reported in 3 (21.4%) and positive family history for autoimmune disease in 5 (35.7%) patients. At disease onset mean laboratory values and range were: Hb 10.5±3.38 gr/dl (4–14.5 gr/dl), WBC 6,233±3,593 /mm^3 (1,700–13,100/mm^3), N 3,282±3,166/mm^3 (100-9,442/mm^3), PLT 22,546±20,970/mm^3 (2,800-62,000/mm^3), LDH 372±302 U/L (226±1,162U/L), bilirubin 1.8±1.78mg/dl (0.3-4.8mg/dl). DAT was positive for IgG - IgG/C3d in 13 patients (92.9%) and for IgG/IgA in one patient (7.1%). As to immunology, 5 (35.7%) patients presented with mild IgG and/or IgM hypogammaglobulinaimia, 2 (14.3%) patients with decreased CD4/CD8 ratio, 3 (21.4%) with increased CD3+*TCRαβ*+CD4-/CD8- double negative T cells and 3 (21.4%) with persistently low C4. EMA were found positive in 2 (14.3%) and anti-TPO and/or anti-TG in 3 (21.4%) patients. In 10 (71.4%) cases simultaneous, whereas in 4 cases (28.6%) sequential cytopenia presence were reported. All patients presented with thrombocytopenia, all with positive DAT - but only 8 (57.1%) with Hb<11g/dl-, 7 (50%) with leucopenia and 6 (42.8%) with neutropenia. Severe presentation was reported at disease onset in 10 (71.4%) patients. All patients received IVIG (1-6g/kg) and high dose methyl-prednisolone (30mg/kg/H) – one or more times depending on clinical course. Prednisolone was administered in 10 (71.4%), cyclosporine in 8 (57.1%) and vincristine in 1 patient. Mean follow-up was 5.4 years (18 months - 13 years), during which 5 (35.7%) patients presented with one or more complications related to treatment: Cushing syndrome, osteopenia, hypertension, renal dysfunction and/or peripheral neuropathy. No severe infection or death was reported during the 15 year period. Disease relapses (1-3) were reported in 8/14 (57.1%) patients. With regards to outcome, 8/14 (57.1%) remained in LCR, 1 (7.1%) in SCR, 1 (7.1%) in PR, 3/14 (21.4%) in active disease, whereas 1 patient was lost to follow-up.
Summary/Conclusions: The rare entity of Evans syndrome in childhood seems to be associated with various immune manifestations and to carry complications related to treatment. Long term studies are needed to guide optimal management, which still remains challenging.

E1415

LOW DOSE RITUXIMAB IS A USEFUL ADDITION TO CORTICOSTEROIDS FOR NEWLY DIAGNOSED PATIENTS WITH WARM AUTOIMMUNE HEMOLYTIC ANEMIA
A. Gomez-De Leon[1,*], P. Colunga Pedraza[1], P. Santana-Hernandez[1], G. Sotomayor-Duque[1], L.D.C. Tarin-Arzaga[1], J.C. Jaime-Perez[1], C.H. Gutierrez-Aguirre[1], O.G. Cantu-Rodriguez[1], D. Gomez-Almaguer[1]
[1]Hematology, Hospital Universitario Dr Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico

Background: Warm autoimmune hemolytic anemia (wAIHA) is an infrequent autoimmune disorder with a high response rate to corticosteroids, albeit relapses are common. Low-dose rituximab has been used successfully in autoimmune cytopenias in an effort to increase response duration, while reducing adverse effects and costs associated with a traditional rituximab dose and prolonged prednisone exposure.
Aims: To evaluate the safety and efficacy of low-dose rituximab combined with corticosteroid treatment in newly diagnosed patients with wAIHA.
Methods: We performed a single-center, prospective, single-arm, open-label study in adult patients with newly diagnosed "primary" or idiopathic wAIHA from 2013-2016 using high-dose dexamethasone (40mg IV days 1-4) followed by prednisone 1mg/kg PO with slow tapering combined with low-dose rituximab (100mg total dose, days +1, +8, +15, +22). CR was defined as an increase in hemoglobin (Hb) ≥12 g/dL, PR was defined as Hb ≥10 g/dL or an increase of ≥2 g/dL. Response was evaluated at day +28, months +6 and +12. Informed consent was obtained from all participants.
Results: Eight patients were included, median age was 32 years (range 18-42), 6 were female. Median Hb at diagnosis was 5.8 g/dL (range 4-8.2 g/dL). All patients had response at day +28 (50% CR rate); median time to response was 12 days (range 3-17). During follow-up 7/8 achieved CR (median time to CR: 30 days, range 15-103), all of which were sustained at 6 months. Median follow-up was 24 months (range 8-40). One patient remained steroid-dependent and relapsed after 12 months, achieving a stable PR after re-treatment with low-dose rituximab. Furthermore, two patients had new-onset immune thrombocytopenia (IT; Fisher-Evans' syndrome), without hemolysis 6.5 and 8 months

after diagnosis. Two patients were diagnosed with systemic lupus erythematosus during follow-up, they remained in CR. Twelve-month CR rate was 80% (5 evaluable patients). One patient experienced grade 3 neutropenia two months after the last rituximab infusion that resolved without complications. Estimated relapse-free survival was 80% at 2 years (60% if IT is considered). No patient had a splenectomy performed.
Summary/Conclusions: This small study reports favorable outcomes for patients with newly diagnosed wAIHA treated with low-dose rituximab, and adds 8 patients with similar responses to the 7 cases previously published by the Italian group in 2012 and 2015. These results may be comparable to standard doses of rituximab, with a lower cost, and deserves further inquiry. The emergence of additional autoimmune phenomena (SLE, Evans' syndrome) is unpredictable and can be an obstacle for appropriate data analysis in prospective AIHA studies.

E1416

INFECTIOUS COMPLICATIONS IN PRIMARY AUTOIMMUNE NEUTROPENIA OF CHILDHOOD

T. Palianopoulos[1], A. Gkoutsias[1], N. Chaliasos[1], A. Makis[1,*]
[1]Department Of Pediatrics, University Hospital Of Ioannina, Ioannina, Greece

Background: Primary autoimmune neutropenia (PAN) of childhood is caused by the action of antibodies against membrane antigens of neutrophils leading to their peripheral destruction. Despite the low neutrophil counts, it is characterized by minor intercurrent infections with rare severe bacterial episodes, which can be a significant cause of morbidity.
Aims: The retrospective evaluation of the incidence and characteristics of infectious complications in children with PAN from one reference academic center in Greece.
Methods: The study included the clinical and laboratory findings of children with PAN, who were diagnosed in our department in the last eight years (2008-2016). All children had neutropenia lasting over 3 months with a positive test for neutrophil antibodies, using the granulocyte immunofluorescence test, the granulocyte agglutination test and the monoclonal antibody immobilization of granulocyte antigen test. Laboratory evaluation for nutritional deficiencies, infections, systemic autoimmune diseases or malignancies was negative. Clinical data related to the occurrence of bacterial infections and treatment, hospitalization and outcome were collected and analyzed.
Results: 48 children with PAN were enrolled; 28 were boys, the median age was 14.5 months (range 5-96) and median follow-up time was 20 months (range 4-93). 19 children (39.6%) all suffering from severe neutropenia (<0.5 x 10^9/L) had to be hospitalized 25 times for bacterial infections; 4 for pneumonia, 7 for acute otitis media, 1 for mastoiditis, 7 for urinary tract infections, 4 for bacterial infections of unspecified site,1 for perianal abscess and 1 for cellulitis, all with good outcome with proper antibiotic treatment. The average number of hospitalizations due to infections was 0,52/patient and the rate was 0.56/1000 patient-days. G-CSF was administered in 2 children due to severe infection, while 8 children received antibiotic chemoprophylaxis.
Summary/Conclusions: Although rare, infections are an important clinical issue in the management of children with severe PAN, sometimes requiring hospitalization. Early signs of infection should be promptly recognized and accordingly treated.

E1417

NEW EPO-RECEPTOR MUTATION IN A -17 YEAR OLD WOMAN WITH ERYTHROCYTOSIS

B. Robredo[1,*], L. Lo Riso[1], B. Lopez[1], L. Florensa[2], L. Arenillas[2], B. Belosillo[2], C. Ballester[1], A. Perez[1], A. Sampol[1], M.A. Duran[1]
[1]Hematology, Hospital Universitario Son Espases, Palma de Mallorca, [2]Laboratorio Citología Hematológica. Servicio de Patología. Gretnhe. Escuela de Citología Hematológica Soledad Woessner., Hospital del Mar, Barcelona, Spain

Background: Erythrocytosis is defined when red cell, hematocrit (Hct) and hemoglobin (Hb), are elevated above normal limits. Causes of erythrocytosis can be primary and secondary. Secondary causes are divided into congenital and acquired. There is a group of patients with idiopathic erythrocytosis.
Aims: We present a case report of a novel EPO-Receptor mutation.
Methods: We present a case report of a 17-year-old woman with erythrocytosis. In the control blood test she had hemoglobin of 18.6g/dl and hematocrit of 62%. We contacted the patient and she attended hematology consultations for study and treatment with phlebotomy.The patient had no known drug allergies or toxic habits. She didn't have any known comorbidities or previous treatment. At evaluation she referred chronic headache without other symptoms. The physical examination was normal. At that time, three possible diagnose were suspected. Firstly, primary erythrocytosis, polycythemia vera (PV). In this disease, the bone marrow produces many red cells and the JAK2 V617F mutation has been demonstrated in the majority of patients. Exon 12 mutation has been described in patients with PV who did not have the JAK2 V617F mutation. The erythropoietin (EPO) level is undetectable as a compensatory mechanism. In our patient, JAK2 V617F mutation and exon12 mutation were negative and the EPO levels were undetectable (<1.5). The bone marrow aspirate and the bone marrow biopsy were normal. These results show that this patient doesn´t present PV, due to she only fulfilling one diagnosis criteria of PV. Secondly, acquired secondary erythrocytosis can be produced as a compensatory mechanism, including: cardiac or pulmonary disease, smoking, renal artery stenosis, sleep apnea/hypoventilation and malignant tumors. In the patient, pulmonary function test, abdominal ultrasound and kidney function were normal. Endogenous erythroid colonies were positive. Due to the test results, we ruled out the diagnosis of acquired secondary erythrocytosis. Finally, congenital secondary erythrocytosis. Genetic abnormalities have been identified in congenital causes of erythrocytosis. The congenital erythrocytosis are divided into two sets according to EPO levels. If the EPO levels are normal or increased, the patient could present high oxygen-affinity hemoglobin because of bisphosphoglycerate mutase deficiency or mutations in the genes in the oxygen sensing pathway. However, if the EPO levels are decreased, the patient could present an erythropoietin-receptor mutation. Our patient presented undetectable EPO levels and the EPO-receptor mutation was requested. The patient has been treated with phlebotomies and aspirin due to headache with good evolution. In this moment, she presents hematocrit levels of 46.8%.
Results: The test revealed an EPO-receptor mutation (c.1275_1290dup), which had never been described before.

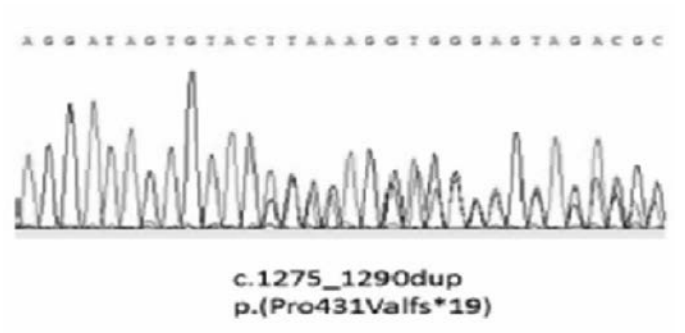

Figure 1.

Summary/Conclusions: The study of the patient with erythrocytosis must begin with a full medical history and confirmation of raised Hb and Hct. In the study of erythrocytosis, after ruling out primary and acquired causes we should always consider the possibility of congenital erithrocytosis, which often is underestimated. When EPO binds to its receptor a signaling cascade is activated, which cause red cells to be produced. This process is switched off when sufficient red cells have been produced by binding of SHP-1. EPO-receptor mutation results in failure of bind of SHP-1, causing uncontrolled production of red cells and erythrocytosis. We describe a new EPO-receptor (c.1275_1290dup) (figure1).

FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN CHILDREN

Z. Salcioglu[1,*], G. Aydoğan[1], F. Akici[1], C. Bayram[1], A. Ayçiçek[1], G. Özdemir[1]
[1]Pediatric Hematology and Oncology Clinic, İstanbul Kanuni Sultan Süleyman Education and Research Hospital, İstanbul, Turkey

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is an autosomal recessive disorder characterized with uncontrolled activation of T-helper lymphocytes and macrophages and over-release of inflammatory cytokines. The only curative treatment is hematopoetic stem cell transplantation (HSCT).
Aims: This study evaluates the clinical and laboratory data of children with FHL. Thirty five FEL cases followed and treated at our clinic between 2005 and 2017 were retrospectively evaluated in our study.
Methods: Information of patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005. All patients vere treated with HLH-2004 protocol. HSCT was performed in nine patients.
Results: Twenty one of the cases were boys and fourteen were girls. The age at presentation for patients was two week-three years (mean 6.2 months). There was a history of consanguineous marriage in 26 of the families(74%). Fever, anemia, and hypertriglyceridemia were present in all HLH cases. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (85.7%). Hypofibrinogenemia was detected in all patients. All patients had neutropenia and thrombocytopenia. Hyperferritinemia was present in 94%% of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF(25.7%). Mutation analysis were performed in 18 patients and of these, 10 had PRF1, 5 had UNC13D, and 3 had STX11 gene mutation. All patients vere treated with HLH-2004 protocol. Of the 22 children who were placed in first remission. HSCT was performed in 9 patients (%25.7). The overall mortality rate was 57% (20 cases) in our series. Twenty children died opportunistic infection (n=10) or of disease progression (n=10).

Summary/Conclusions: In conclusion, FHL is a disease with high mortalite rates and the only curative treatment is HSCT. Donor search for HSCT must be started and HSCT should be performed after the remission.

E1419

ABNORMAL MONOCYTE POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH CHRONID IDIOPATHIC NEUTROPENIA

M. Velegraki[1,*], V. Kaliafentaki[1], H. Koutala[1], A. Damianaki[1], M. Ximeri[1], P. Kanellou[1], I. Mavroudi[1], C. Pontikoglou[1], H. Papadaki[1]
[1]Department of Haematology, University of Crete School of Medicine, Heraklion, Greece

Background: Chronic idiopathic neutropenia (CIN) is an acquired disorder of granulopoiesis characterized by an unexplained, prolonged reduction in the number of neutrophils and a generally benign and uncomplicated course. Neutropenia in CIN has been mainly attributed to increased apoptotic death of the granulocytic progenitor cells due to abnormal production of pro-inflammatory cytokines and pro-apoptotic mediators. Activated T-lymhocytes with a skewed oligoclonal/monoclonal profile and myelosuppressive properties have also a major role in the pathophysiology of CIN.
Aims: Monocyte subpopulations display a prominent role in innate immunity but also mediate pro-inflammatory responses and T-cell activation. The monocyte subsets have never been studied in CIN. The aim of the present study was to evaluate the monocyte subsets, namely the classical $CD14^{++}/CD16^{-}$, intermediate $CD14^{++}/CD16^{+}$ and non-classical $CD14^{+}/CD16^{++}$ cells as well as the monocytic $CD14^{+}/CD15^{-}/DR^{neg/low}/CD33^{+}/CD11b^{+}$ fraction of the myeloid derived suppressor cells (MDSC), in CIN patients.
Methods: We have studied 25 patients fulfilling the well-defined diagnostic criteria for CIN and 10 age and sex-matched healthy individuals. Three-colour flow cytometry was used to assess the peripheral blood monocytes subsets in the gate of CD14 positive cells and five-colour flow cytometry for the evaluation of the myeloid derived suppressor cells in the gate of cells with intermediate/high FSC/SSC properties.
Results: The mean number of neutrophils and monocytes in CIN patients was 1176±496/μl and 412±130/μl, respectively (range 200-1800/μl and 200-700/μl, respectively). The proportion of classical $CD14^{++}/CD16^{-}$ cells was significantly decreased in CIN patients (79.69%±7.60%) compared to the healthy individuals (87.90%±3.70%) (P=0.0009). In contrast, a significant increase was observed in the proportion of CD16 positive cells in CIN patients (16.81%±6.75%) compared to the controls (7.97%±3.16%) (P=0.0001). This increase was due to the higher proportion of the intermediate $CD14^{++}/CD16^{+}$ but not the non-classical $CD14^{+}/CD16^{++}$ monocyte subsets in CIN patients (12.74%±5.28% and 4.05%±2.51%, respectively) compared to controls (7.05%±2.47% and 2.73%±1.39%, respectively) (P=0.0014 and P=0.1383, respectively). Furthermore, the proportion of $CD14^{+}/CD15^{-}/DR^{neg/low}/CD33^{+}/CD11b^{+}$ MDSCs was significantly increased in the patients (6.18%±3.92%) compared to the healthy controls (3.31%±1.74%) (P=0.0412).
Summary/Conclusions: CIN patients display increased proportion of circulating intermediate $CD14^{++}/CD16^{+}$ monocytes that may have a role in the aberrant inflammatory responses commonly seen in these patients. The increased proportion of the $CD14^{+}/CD15^{-}/DR^{neg/low}/CD33^{+}/CD11b^{+}$ MDSC in CIN may simply reflect a compensatory reaction aiming to suppress the T-cell activation. Isolation of the above cell populations and transcriptome studies are currently in progress in our laboratory.

DIAGNOSTIC VALUE OF CELL BOUND AND CIRCULATING ANTI-NEUTROPHIL ANTIBODY DETECTION IN PEDIATRIC NEUTROPENIA

L. Porretti[1,*], P. Farruggia[2], V. Trunzo[3], R. Ghilardi[4], N. Mirra[4], L.D. Notarangelo[5], B. Martire[6], S. Milani[7], C. Vener[7], P. Rebulla[4]
[1]Flow Cytometry Service, IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, Milan, [2]A.R.N.A.S. Ospedale Civico Di Cristina e Benfratelli, Palermo, [3]Flow Cytometry Service, IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, [4]IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, Milan, [5]Azienda Ospedaliera Spedali Civili, Brescia, [6]Azienda Ospedaliero Universitaria Policlinico Giovanni XXIII, Bari, [7]Department of Clinical Sciences and Community Health, Milan, Italy

Background: Chronic benign neutropenia (CBN) of infancy includes primary autoimmune (pAIN) and chronic idiopathic (CIN) neutropenia. A diagnosis of CIN is supported by the absence of demonstrable anti-neutrophil autoantibodies, which can be detected free in the serum and bound to neutrophils with the Indirect- and Direct-Granulocyte Immunofluorescence Test (I-GIFT, D-GIFT), respectively. Conclusive evidence is lacking on the diagnostic value of the D-GIFT, whose performance requires specific laboratory expertise, may be logistically difficult and hampered by very low neutrophil count in patient samples.
Aims: This study investigated whether the evaluation of D-GIFT improves the diagnostic accuracy of pediatric neutropenia.
Methods: I-GIFT and D-GIFT were performed by flow cytometry in 533 children including 174 (33%), 162 (30%), 81 (15%), 51 (10%) and 65 (12%) cases with pAIN, CIN, secondary autoimmune (sAIN), post-infection (PIN) and non-autoimmune (nAIN) neutropenia referred to this laboratory during 2002-2014, respectively.
Results: Using highly specific median fluorescence intensity cut-off values calculated by ROC curves, a positive D-GIFT was found in 49% of CIN patients, who showed similar clinical features as those included in the pAIN group. In 44 (27%) of 162 CIN patients I-GIFT was repeated 2-3 times in a year, resulting positive in 12 (27%) and 2 (5%) patients at the second and third screenings, respectively. Interestingly, 10 (71%) of the latter 14 patients showed a positive D-GIFT at the first serological screening.
Summary/Conclusions: D-GIFT evaluation improves the diagnostic accuracy of pediatric neutropenia. This can reduce the need for expensive and invasive investigations in CBN patients.

E1421

INAPPROPRIATE TREATMENT COULD MASK COBALAMIN DEFICIENCY: ROLE OF METHYLMALONIC ACID EVALUATION

R. Angel F.[1,*], P. Sarda[2], M. Serra[1], J.M. Queralto[2], E. Zapico[2], J. Remacha[1], S. Payan[1], A. Ramos-Aviles[2]
[1]Hematology, [2]Biochemistry, Hospital de Sant Pau, Barcelona, Spain

Background: Metabolic markers of cobalamin (Cbl) deficiency, such as methylmalonic acid (MMA) and homocysteine (Hcy) enable us to diagnose Cbl deficiency1,2. They differentiate Cbl deficient patients from those with low serum cobalamin levels (LB12), but without a real Cbl deficiency. Hcy evaluation is fully automated and available in many laboratories, whereas MMA determination is cumbersome and measured in few laboratories3. Routinely, Hcy is used to differentiate LB12 patients because a good concordance has been reported between Hcy and MMA4. However, in a study involving few cases, 26.5% patients with LB12 and normal Hcy showed high MMA levels4.
Aims: To evaluate the characteristics of patients with LB12 and normal Hcy and high MMA levels.
Methods: A prospective study was carried out in our University Hospital. Hcy levels were determined in LB12 (level <150pmol/l) patients with normal folate parameters for 18 consecutive months. MMA was assessed in those with normal Hcy. Serum B12, serum and red cell folate, and Hcy levels were evaluated using commercial automated methods. Hyperhomocysteinemia was defined by serum Hcy >17μmol/l. Serum MMA was assessed by using mass spectrophotometer and an increase in the MMA level was considered when MMA was >0.4nmol/l.
Results: A total of 237 patients with LB12 and normal Hcy were observed. In 27 (11.4%) MMA levels could not be determined. MMA levels were normal in 147 (70%). In 63 patients, MMA was increased (30%), including 25 cases (12%) with MMA levels >0.8nmol/l. In 48 out of 63 patients (76%), data on previous treatment were available. Of them, 40 (83.3%) patients had previously received inappropriate treatment (40% receiving folate) and 5 no previous Cbl treatment (10.5%). Only, 3 patients (6.25%) were treated with an adequate Cbl dosage.
Summary/Conclusions: MMA was increased in 30% of LB12 patients with normal Hcy, demonstrating cobalamin deficiency. Most of these patients (83%) were erroneously treated, including 40% receiving folate. As a consequence, in most of these cases this erroneous treatment decreased Hcy levels to normal values, but cobalamin deficiency was masked and could deteriorate, especially when folate treatment was used without and adequate cobalamin replacement.

RITUXIMAB IN AUTOIMMUNE HEMOLYTIC ANEMIA OF INFANCY

M. Economou[1,*], A. Teli[1], D. Adamidou[2], A. Taparkou[1], E. Farmaki[1]
[1]Aristotle Universtity of Thessaloniki, [2]Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Autoimmune hemolytic anemia (AIHA) is not commonly seen during childhood, and is extremely rare in infancy. Absence of guidelines renders management of the disease difficult in children – and even more so in infants.
Aims: Aim of the report is to present a number of cases of infantile AIHA, refractory to conventional treatments, demonstrating response in administration of rituximab.
Methods: The report concerns four infants (3 baby girls and one baby boy) who presented with AIHA. Data regarding demographics, personal and family medical history, immunologic assessments, previous treatments and response to rituximab were studied.
Results: Age at diagnosis of AIHA was 4-6 months. In 3 cases (cases number 1, 2 and 3) personal and family history, as well as laboratory screening at diagnosis, did not reveal presence of any other hematologic, autoimmune or immunologic condition. In case number 4 AIHA followed the diagnosis of giant cell hepatitis. Hospitalization before rituximab administration ranged between 1 and 4 months, and included multiple transfusions, administrations of intravenous immunoglobulin (maximum dose 6g/kg), repeated doses of intravenous methyl-prednisolone (30mg/kg) followed by oral prednizolone (max 5mg/kg), all failing to achieve sustained response. Rituximab was administered at 375mg/m^2 in 4 weekly infusions. In 3 infants 5 monthly infusions followed. Stabilization of hemoglobin and improvement of hemolysis parameters were observed after the 3rd-4th weekly infusion in all infants. In 3 patients (no 1,2,3) CD19+ and CD20+ B cell assessment before and after rituximab administration was performed. Complete elimination (<1%) was observed in all patients after the 1st-2nd infusion. Despite B cells returning to normal 11 months after treatment, infant no 1 remained in clinical remission during follow-up (22 months post treatment). Infant no 2 remained in clinical remission for the 16 month post treatment follow-up, despite B cell normalization. Infant no 3 relapsed following B cell normalization, 11 months after rituximab administration. Infant no 4 did not undergo B cell measurements and relapsed one year after completing rituximab therapy. The 2 patients that relapsed were re-treated with 4 rituximab infusions: patient no 3 remained well for the 18 month follow-up, whereas patient no 4 remained well for 10 years – again relapsing and receiving her 3rd rituximab treatment with good response for the remaining 7 month follow-up. None of the patients presented with adverse reactions during the infusions or with severe infections as a result of immunosuppression. However, infant no 1 developed asymptomatic progressive IgG hypogammaglobulinemia 11 months after initial exposure to rituximab, eventually requiring IVIG administration.
Summary/Conclusions: Rituximab administration in refractory AIHA seems to be efficacious and safe in infants. However, close follow-up is warranted in order to ensure absence of long term complications, including the risk of post-treatment hypogammaglobulinemia, when the drug is administered at such young ages.

E1424

EARLY LESSONS FROM WHOLE-GENOME SEQUENCING IN THE CLINICAL DIAGNOSIS OF RARE INHERITED ANAEMIAS

N. Roy[1,2,*], C. Camps[3], H. Dreau[2], S. Knight[3], E. Kvikstad[3], M. Pentony[3], C. Babbs[4], C. Scott[4], K. Wray[4], A. Schuh[2], J. Taylor[3]
[1]Molecular Haematology Unit, [2]BRC Molecular Diagnostic Centre, Oxford University Hospitals NHS Trust, [3]Comprehensive Biomedical Research Centre, Wellcome Trust Centre for Human Genetics, University of Oxford, [4]Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Targeted re-sequencing has recently been adopted for the rapid diagnosis of anaemia patients whose disease is likely to have a genetic basis, however, currently results remain inconclusive in 30-60% of cases. Whole-genome sequencing (WGS), provides more uniform coverage than amplification-based panels and is allied to an unbiased approach offering the opportunity to explore both coding and non-coding regions. It is also possible to use WGS data to detect copy number variation with good resolution and sensitivity. Therefore WGS has the potential to offer an accurate molecular diagnosis in a proportion of unsolved anaemia cases and may therefore be a superior initial approach. Furthermore, WGS is likely to lead to the identification of novel genes involved in pathogenic and normal erythropoiesis.
Aims: We aimed to undertake WGS in a set of patients in whom targeted re-sequencing had not been able to identify a molecular cause for the inherited anaemia, in an attempt to increase the diagnostic yield of the molecular analysis of such patients and provide novel candidate genes as causative of anaemia.
Methods: We performed WGS of 20 individuals (2 singletons and 6 trios) at 30X coverage where all the probands have a rare anaemia of suspected genetic origin. Probands were pre-screened with a targeted panel containing ~50 candidate genes, none of which had harboured likely causative variants. Analysis of WGS data involved Stampy for read alignment, Platypus for variant calling and Ingenuity Variant Analysis (Qiagen) for variant annotation and filtering, followed by visual inspection and verification by Sanger sequencing.
Results: Known causative variants in a gene absent from the targeted panel were detected in two patients (25%), whereas candidate variants in novel genes not previously associated with anaemia were identified across the other six cases. Familial segregation and functional studies are underway to provide further evidence of causality for these novel variants, of which 60% are in genes with previous evidence of a role in erythropoiesis and 40% in genes with no known role in erythroid development.
Summary/Conclusions: These results illustrate the overlap in phenotypic abnormalities existing among these conditions and the importance of providing an accurate molecular diagnosis to enable correct diagnostic and clinical management of anaemia patients. We also demonstrate the benefit of using WGS over targeted resequencing given the difficulty of designing comprehensive gene panels and keeping them up-to-date as new candidate genes are identified.

E1425

CONGENITAL ERYTHROCYTOSIS: DISCOVER OF A NEW MUTATION

J. Barradas[1,*], P. Rocha[1], C. Dantas Rodrigues[1], C. Constanço[1], M. Reis Andrade[1], C. Bento[2], H. Matos Silva[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar Tondela-Viseu, Viseu, [2]Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Congenital erythrocytosis (CE) is a rare hereditary disorder of red cell production, characterized by an absolute increase in red cell mass with elevated hematocrit and hemoglobin levels not accompanied by increased numbers of white cells and platelets. It can be caused by defects in the EPO-induced signaling pathway (primary), defects in the control of EPO synthesis by the oxygensensing pathway (secondary) or sinthesis of high oxygen affinity hemoglobins. EPO transcription is regulated by Hypoxia Inductable Factor (HIF). 3 prolyl hydroxylase domain proteins (PHD1, PHD2, PHD3), active in the presence of oxygen, are able to hydroxylate key prolines in oxygen depedent degradation domains of HIF alpha subunit and it is degradated by the proteosome. Mutations in those proteins are linked to CE.
Aims: Describe a new mutation in PHD2 gene associated to CE.
Methods: Clinical process consultation and search in Blood, European Hematology Association and Pubmed websites of keywords: "congenitalfamilial erythrocytosis" "phd2".
Results: We described a portuguese family followed by hematology service because of an isolated but sustained erythrocytosis, affecting 3 generations - grandfather, father (propositus) and son. Propositus referred headache and presented plecthoric face and hypertension. Analytically, it was confirmed erythrocytosis (haemoglobin>18g/dL and hematocrit>50%), without any other changes, except an indirect hyperbilirubinemia. Secondary causes of erythocytosis was excluded, with normal EPO and partial oxygen pressure. Bone biopsy only showed an erythroid hyperplasia, no JAK2 mutations identified, and normal hemoglobins electrophoresis, HBB and EPOR gene sequencing. We then proceeded to sequencing of gene included in EPO-induced signaling pathway and it was detected a new mutations in PHD2 gene (F366L), in heterozigoty. Despite it has never been described, other mutations in PHD2 were associated to slightly increased thrombotic potential so patients began antiplatelet aggregation therapy and phlebotmies. Additionally, they were diagnosed with Gilbert syndrome by a mutation in UGT1A1 gene promoter region [A(TA)7TAA].
Summary/Conclusions: An unknown mutation of PHD2 has been detected in 2 generation of a family with erythocytosis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of EPO production and subsequently in erythropoiesis. Futhermore family studies have to be performed to better understand its pathogeny and management.

E1426

A RETROSPECTIVE STUDY OF THE THROMBOTIC MICROANGIOPATHIES DIAGNOSED IN THE LAST 17 YEARS IN ONE SINGLE CENTRE

A. Esteban Figuerola[1,*], M.M. Olona Cabases[2], R. Vallansot[1], C. Talarn Forcadell[1], J. Do Nascimento[1], R. Aguinaco Culebras[1], C. Araguás Arasanz[1], A. Martínez Roca[1], T. Giménez Pérez[1], M. Cervera Calvo[1], M. Solà Fernández[1], J. García Arroba[1], L. Ramiro Infate[1], A. Martínez Bea[3], A. Bodí Saera[4], J. Sarrà Escarre[1], L. Escoda Teigell[1]
[1]Hospital Joan XXIII Tarragona, Tarragona, Spain, [2]Preventive Medicine Unit, [3]Nefrology, [4]Intensive Care Unit, Hospital Joan XXIII Tarragona, Tarragona, Spain

Background: Thrombotic microangiopathies (TMA) are characterized by the formation of platelet thrombi that obstructs vital organ microcirculation. The presence of the 5 classic parameters (haemolytic anemia, thrombocytopenia, fever, oliguria and neurological affection) is rare. ADAMTS13 determination allows a more accurate diagnosis than the presumption based on clinical and biochemical parameters.
Aims: To retrospectively analyze 44 TMA patients diagnosed in our centre in the last 17 years and characterize TTP, HUS and secondary TMA (sTMA) by revising their clinical data, correlate with ADAMTS13 level and identify predictors for survival and relapse.
Methods: TMA was defined as microangiopathic hemolytic anemia with thrombocytopenia under 150x10^9/L. All cases were classified as: 1. TTP (TMA with

ADAMTS13 <5% or TMA without baseline cause), 2. HUS (TMA with ADAMTS13 >5% and high creatinine level or positive E. Coli Shiga-Toxin or HUS related mutation), 3. sTMA (other TMA with a definite triggering cause). Clinical and laboratory parameters were analyzed in each group (TTP/HUS/sTMA) (ADAMTS13 ≤5% or >5%) by a univariate analysis using chi-square for categorical variables and ANOVA test for continuous variables. Kaplan Meier and multivariate Cox proportional hazards regression was used for survival and relapse.

Table 1.

Table 1. Univariate analysis for TTP, HUS, sTMA and ADAMTS 13 level. *Data is shown as mean and standard deviation (SD) or percentage of cases.*

	GLOBAL (N=44)	TTP (N=13)	HUS (N=8)	TMA (N=23)	P VALUE	ADAMTS13 >5% (N=20)	ADAMTS13 ≤5% (N=8)	P VALUE
LDH (u/l)	2483 (1923)	3612 (2658)	3936 (957)	2039 (1426)	0.04	2136 (1444)	3230 (1817)	*0.098*
Bilirubin (mg/dl)	1.49 (1.50)	2.53 (1.72)	0.75 (0.40)	1.38 (1.36)	0.008	1.09 (1.30)	2.06 (1.18)	*0.078*
Schistocytes (x100 erythrocytes)	3.6 (4.8)	6.7 (7.4)	2.6 (1.8)	2 (1.8)	0.015	2 (1.7)	7.7 (8.7)	0.009
Platelets (x10³/l)	53.32 (39.64)	15.54 (10.12)	77.75 (32.87)	66.17 (37.94)	0.0001	67.85 (34.88)	15.63 (11.82)	0.000
Creatinine (mg/dl)	3.66 (4.28)	1.03 (0.50)	7.02 (4.05)	3.96 (4.72)	0.005	4.71 (4.02)	1.06 (0.61)	0.018

Splenectomy	11.4%	38.5%	0	0	0.001	0	50%	0.003
Overall survival	-	92.3%	100%	65%	0.23	89.4%	100%	0.37
Disease free survival	-	68.6%	80%	100%	0.02	92.3%	47.6%	0.04

Five-year overall survival and disease free probabilities (%). TTP thrombotic thrombocytopenic purpura, HUS hemolytic uremic syndrome, TMA secondary thrombotic microangiopathy, LDH lactate dehydrogenase.

Results: Patient distribution was: TTP 13, HUS 8, sTMA 23. ADAMTS13 was determined in 28 patients (low 8, high 20). Clinical and laboratory parameters of each group and univariate analysis are summarised in table 1. All patients received 1mg/kg/day steroids on admission and started plasma exchange. Patients in the TTP group showed increased levels of LDH, schistocytes, bilirubin and a low platelet count which was associated with bleeding. They also required a higher number of plasma exchanges to recover. Five patients relapsed, 4 with low ADAMTS13 level. 4 patients were splenectomized and received immunomodulators. One patient received only plasma exchanges when relapsed. One patient died immediately after diagnosis before receiving plasma exchange. HUS group patients had higher creatinine level which was associated with oliguria and dialysis requirement. Neurological symptoms were more frequent as well. Two patients progressed to renal failure and one was transplanted. Two other patients received eculizumab and 1 relapsed when treatment was interrupted during pregnancy. sTMA patients showed more cardiac events and fever. Main triggering causes were: 6 malignant hypertension, 5 systemic lupus erythematosus, 4 neoplasia, 3 pancreatitis, 2 pregnancy, 1 tuberculosis, 1 glomerulonephritis, 1 dermatomyositis. Six patients died (4 cancer related). In the multivariate analysis, high LDH level was significantly associated with relapse (p=0.012) while the number of schystocytes showed a trend to statistical significance (p=0.063).
Summary/Conclusions: ADAMTS13 determination is a useful tool in TMA differential diagnosis. A high LDH level, and also probably the number of schystocytes, could be valuable to predict relapse in TMA patients.

E1427

CHILDREN WITH CHRONIC-REFRACTORY AUTOIMMUNE CYTOPENIAS: A SINGLE CENTER EXPERIENCE

T.H. Karapınar[1,*], E. Durgun[1], Y. Oymak[1], N. Gülez[2], Y. Ay[1], F. Genel[2], S. Gözmen[1], E. Serdaroğlu[3], S. Aydın Köker[1], E. Töret[1], C. Vergin[1]
[1]Pediatric Hematology and Oncology, [2]pediatric immunology, [3]pediatric nephrology, Dr. Behcet Uz Children Training and Research Hospital, Izmir, Turkey

Background: Autoimmune cytopenias are a group of heterogeneous disorders characterized by immune-mediated destruction of one or more hematopoietic lineage cells. They can be idiopathic or occur as a manifestation of other underlying disorders, such as autoimmune diseases, immunodeficiency, autoimmune lymphoproliferative syndrome, tumors, medications or infections.
Aims: The aim of this study was to evaluate the clinical course and significance of autoimmune cytopenias due to immunodeficiency or autoimmune diseases in children followed up at our hospital.
Methods: A total of 337 files of information belong to patients with chronic or refractory autoimmune cytopenias were evaluated retrospectively at our hematology department between February 1997 and September 2015. Ultimately, patients with immune deficiency or autoimmune diseases (23 patients) were included in this study. Data were analyzed using SPSS 15.0. The results are presented as the mean, SD, median, absolute number, or percentile.
Results: Twenty-three of the patients with chronic or refractory autoimmune cytopenias (6.8%) had an immune deficiency or an autoimmune disease. The median age of diagnosis was 3.1 years (between 6 months-16 years) and the ratio of male/female was 1.3. The median duration of following was 2.6 years (between 4 months and 18.5 years). A total of 13 patients (56.5%) had single-lineage cytopenias and 10 (46.5%) had multi-lineage cytopenias. Shows last diagnosis of the patients. In 22 of the patients, firstly cytopenias had detected than the primary diseases were diagnosed after median 2 months (between 0 and 77 months). Only one patient firstly had diagnosed as CVID, cytopenia has developed after years. All of the patients were treated with corticosteroids or intravenous immune globulin (IVIG) as first-line treatment. Ten patients needed second or further-line immunosuppressive therapies including rituximab, mycophenolate mofetil, cyclosporine A, azathioprine, and chloroquine. A total of 8 patients (34.7%) recovered from autoimmune cytopenias after the treatment of primer disease. That diseases were diagnosed as systemic lupus erythematosus in 4 patients, hypogammaglobulinemia in 3 patients, and celiac disease in 1 patient. Cytopenias have countinued in 14 of the patients. One patient with CVID died.
Summary/Conclusions: Cytopenia may be the first finding of an immunodeficiency or autoimmune disease and primary disease may be diagnosed in the clinical course. Early diagnosis is important because of beginning to the early treatment of underlying disease

E1428

INHERITED PROTHROMBOTIC RISK FACTORS IN TURKISH CHILDREN WITH HEREDITARY ANGIOEDEMA. SINGLE CENTER

T. Patiroglu[1,*], M. Cansever[2], A. Ozcan[1], F. Tahan[3], Y. Özkul[4]
[1]Pediatric Hematology, [2]Pedıatric Immunology, [3]Pediatric Allergy, [4]Genetıcs, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Hereditary angioedema (HA) is characterized with recurrent mucocutaneous angioedema, abdominal pain, edema of larynx and extremities. HA is a life treatening, rare disease, it's genetic inheritance known as autosomal dominant. The incidence of the disease ranges from 1/10000 to 1/150000. 3 types of disease were described. Classic HA, is associated with C1 esterase inhibitor quantitative (type 1) or functional (type 2) defficiency. Type 3 HA is defined as form of HA which is seen in pregnant women and women use estrogen treatment. If plasma C1 inhibitor is deficient, complement, kinin-bradykinin, coagulation and fibrinolytic systems activate out of control and then vascular permeability increases and angioedema develops, tendency to thrombosis increases as well. Futhermore, it is known that acute treatment with C1 inhibitor concentrate and prophylactic use of danazol and antifibrinolytic drugs may also stimulate the thromboembolism. Therefore, prothrombotic risk factors are important in the patients with HA. Hence, we planned to search prothrombotic risk factors in patients with HA.
Aims: Hence, we planned to search prothrombotic risk factors in patients with HA.
Methods: Ten patients wih HA who were followed up at the Department of Pediatric Immunology and Allergy of the Erciyes University Medical Faculty were included in our study. The type and frequency of attack, use of prophylaxy and family story of HA were questioned. Factor V G1691A, prothrombin G20210A variant, methylenetetrahydrofolate reductase (MTHFR) and plasminogen activator inhibitor (PAI) mutations were investigated in all patients.
Results: Among the 10 patients of the study, five of the them were male (50%) and five were female (50%) and their ages mean was 151,90±48,21 months old (ranged from 75 to 210 months). No one had parental consanguinity. Nine patients (90%) had the family history of HA. Patients' affected family members were distributed by 5 sibling (50%), 3 mother and aunt (30%), 1 father (10%). One patient had no family story (10%). The mean serum value of C4 level in diagnosis was 4,71±1,62mg/dl (normal value:) mean value of C1 inhibitor level in diagnosis was 50,10±19,22mg/dl (normal value). It was learned that four patients (40%) had an attack of HA once every week, three patients had (30%) once per month, one patient (10%)had, once every 2-3 months. Two patients (%20) had no attack. Four patient had abdominal (40%), four patient had edema of hands, feet and face (40%). None of them received prophylactic treatment. One patient (10%) had heterozygous F V G1691A mutation, another one had also heterozygous protrombin G20210A mutation. The heterozygous MTHFR mutation were identified in seven patients (70%) and homozygous MTHFR mutation were found two patients (20%). Furthermore, four patients (40%) had heterozygous and one patient (%10) had homozygous PAI mutation.
Summary/Conclusions: C1 inhibitor, inhibits activated F XII,thrombin and plasmin. When the C1 inhibitor is deficient, dermal vascular thrombosis and systemic coagulation occur due to inhibition of activated FXII, thrombin and plasmin. Decrease level of PAI1 and PAI2, destructs plasmin activation which cause FXII activation and it effects prekallikrein and bradykinin cascade, therefore increase tendency of thrombosis and HA risk. In the literature, an adult patient who had heterozygous Factor V leiden mutation and purpura fulminans was reported. In our study, there is no clinical evidence supporting thrombosis, nevertheless it was observed that one of our patient with a homozygous PAI mutation had an attack more frequently. As a conclusion, in the patients, risk of thrombosis increases because of both HA and related treatment. Hence, prothrombotic risk factors should be investigate in patients with HA. In HA patients, known to protrombotic risk factors was crucial to estimate attack frequency-severity and treatment related thrombosis risk.

E1429

FLOW CYTOMETRIC ANALYSIS OF TISSUE SAMPLES IN 42 ADULT PATIENTS WITH MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

M. Klimkowska[1,*], C. Arlinde[1], K. Kosior[1], M. Machaczka[2,3]
[1]Department of Clinical Pathology and Cytology, [2]Hematology Center, Karolinska University Hospital, Stockholm, Sweden, [3]Medical Faculty, University of Rzeszow, Rzeszow, Poland

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, potentially fatal hyperinflammatory syndrome, which in its most common, secondary form, can be induced by infection, malignancy or autoimmune disease. Diagnosis of HLH is made when at least five of eight clinical and laboratory HLH-2004 criteria are met. However, diagnostic criteria were established based on studies from pediatric patients, and it is debated if they can be applied to adults. Assessment of these criteria can be subjective (microscopic identification of hemophagocytes), time-consuming or not easily available (e.g. molecular analyses, functional tests of NK-cells).
Aims: The aim of the study was to evaluate phenotypic findings from flow cytometric (FC) analyses of bone marrow (BM) and other tissue samples from patients with hematological malignancies (hM) who developed HLH. The study was intended to investigate potential utility of a rapid phenotypic screening in diagnostics of suspected HLH.
Methods: Flow cytometric files for 42 patients with hM were retrieved from archive of the Department of Clinical Pathology and Cytology, Karolinska University Hospital. The patients were diagnosed and treated for hM-HLH at the Hematology Center of the same hospital, between 2009 and 2016. Tissue samples (bone marrow, peripheral blood, lymph nodes) were analyzed according to standard procedures, using monoclonal antibodies (BD, DAKO, Beckman Coulter, BioLegend). Cells were acquired using 4-color Canto A or 8-color Canto II cytometers (BD), and analyzed with BD FACSDIVA software. Neoplastic clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow samples were obtained from 31 patients shortly before and from 24 patients following HLH-diagnosis; in 13 patients paired BM samples were available.
Results: Patient characteristics are presented in table 1. Bone marrow B-cell lymphopenia was observed in 67% patients before and 74% after HLH diagnosis. Decreased amounts of NK-cells were noted in 48% persons at both time points. T-cell lymphopenia before HLH diagnosis was noted in 60% patients with myeloid malignancy but in only 25% cases of lymphoid malignancy, whereas in established HLH the respective figures were 27% and 46%. CD4/CD8 ratio was skewed-to-normal in both myeloid and lymphatic tumors before HLH was diagnosed. In cases of confirmed hyperinflammation, patients with myeloid tumors showed dominance of CD4+ cells but no such difference was noted in lymphoid disease. Loss of lineage specific markers of non-neoplastic T-cells was a constant feature in lymphoid malignancy, whereas aberrant expression of lymphatic markers (CD2, CD7, CD56) on myeloid cells was uniform in patients with myeloid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors at HLH onset (40% *vs* 31%), although it was of non-neoplastic character. However, monocytopenia was also noted in cases of established HLH, in 10% of myeloid malignancies and 15% of lymphatic malignancy cases.

Table 1.

Table 1. Patient characteristics.

Characteristics	Number of patients
Sex	
male	27 (64%)
female	15 (36%)
Age at HLH diagnosis [years]	
mean	64
median	57
range	26–85
Type of malignancy	
lymphoid	22 (52%)
myeloid	20 (48%)
Lymphoid malignancies	
T/NK-cell lymphoma/leukemia	7 (32%)
B-cell lymphoma	11 (50%)
Hodgkin lymphoma	3 (14%)
Multiple myeloma	1 (4%)
Myeloid malignancies	
AML (including APL)	15 (75%)
MDS	2 (10%)
MPN	2 (10%)
MDS/MPN	1 (5%)

Summary/Conclusions: In the presented cohort, quantitative shifts could be observed in BM samples around the time of HLH onset. However, different patterns were observed between patients affected by lymphoid or myeloid malignancies, which may represent disease-specific impact on BM microenvironment. Further study will be carried out to confirm findings in a large, possibly prospectively collected patient group. Control group of patients with respective malignancies but without HLH will be included.

Platelets disorders

E1430

BLEEDING IN PRIMARY IMMUNE THROMBOCYTOPENIA: WHO ARE MOST AT RISK?

U. Doobaree[1,*], S. Hodges[1], R. Nandigam[1], A. Newland[1], D. Provan[1]
[1]Haematology, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: Primary Immune Thrombocytopenia is rare disorder in which patients are at risk of bleeding due to autoimmune-mediated platelet destruction.
Aims: This study focused on describing the prevalence and types of bleeding events around the time of ITP diagnosis and after, as well as identify any factors that can potentially influence the risk of bleeding.
Methods: Data from the United Kingdom Immune Thrombocytopenia Registry were analysed for this study. The registry obtained its data from about 70 centres around the UK. Descriptive and logistic regression statistical techniques were used for this study.
Results: This analysis was based on 2365 (57.8% females) participants who are part of the Registry. The median age at diagnosis was 50 years (IQR 32, 66) and 77% of these patients were of European ethnicity. The commonest comorbid conditions was hypertension (23%). Median platelet count was 19 (IQR: 5, 53). Eighty percent had a platelet count below $30x10^9$/L around ITP diagnosis. The most common bleeding events were skin-related (46.5%) and to the oral cavity (14.4%). About 70% of the cohort experienced at least one bleeding event at some point after diagnosis. After ITP diagnosis the most common bleeds were again skin-related (34.3%) and oral cavity bleeding (14.8%). Epistaxis had risen from 11.6% before diagnosis to 17.7%. Bleeding at other sites did drop. However, the prevalence of intracranial haemorrhage rose from 0.9% pre-diagnosis to 1.2% after diagnosis. Prednisolone (79%) and IVIg (43%) remained the most used drugs followed by rituximab (26%) among those were treated. Romiplostim (15%) and Eltrombopag (9%) are used too but not anymore than mycophenolate (18%) and azathioprine (22%). Fourteen percent of the cohort had a splenectomy at some point. Age but not gender or ethnicity were found to be associated with having a bleeding event around the diagnosis of ITP. Young adults (18 to 30 years old) are less likely to experience a bleed than older adults (>70 years), who were most at risk. Platelet counts, expectedly, was associated with bleeding with those presenting with a platelet of $<30x10^9$/L were at higher risk. No comorbid illness or cotherapies were found to be associated with bleeding events.
Summary/Conclusions: The frequency of bleeding decreased for most sites but for some others a slight increase has been observed since ITP diagnosis. It is possible that bleeding events may have been recorded more accurately or observed more closely and over a longer period of time since diagnosis. However, control of bleeding was an issue after the diagnosis of ITP. Future analysis statifying its findings by time periods would be beneficial in describing if bleeding events were better controlled over the last few years, especially after the introduction of new therapeutic agents and the publication of the internal consensus report on the diagnosis and management of primary ITP.

E1431

A MULTICENTRE, SINGLE ARM, OPEN LABEL STUDY EVALUATING THE EFFICACY AND SAFETY OF ELTROMBOPAG IN PATIENTS WITH SEVERE PERSISTENT IMMUNE THROMBOCYTOPENIC PURPURA (ITP) WITHIN SIX MONTHS OF DIAGNOSIS

H. Tran[1,2,*], R. Bird[3], S. Chunilal[4], T. Brighton[5], J. Reynolds[6], S. He[7], C. Mazis[1], R. Hall[1], P. Shuttleworth[7], A. Grigg[7]
[1]Clinical Haematology, The Alfred Hospital, [2]Clinical Haematology, Monash University, Melbourne, [3]Clinical Haematology, Princess Alexandra Hospital, Brisbane, [4]Clinical Haematology, Monash Health, Melbourne, [5]Clinical Haematology, Prince of Wales Hospital, Sydney, [6]Clinical Epidemiology and Preventative Medicine, Monash University, [7]Clinical Haematology, Austin Hospital, Melbourne, Australia

Background: Patients with acute ITP who fail or are dependent on steroids or intravenous immunoglobulin (IvIg) are often committed to splenectomy or prolonged immunosuppression. Splenectomy is potentially curable but not without operative risk with many patients reluctant to undergo surgery, while the response to immunomodulation is often suboptimal with significant side effects. Although effective, to date, there is no published studies evaluating the benefit of eltrombopag among steroid dependent or resistant, non-splenectomised ITP patients diagnosed within 6 months.
Aims: To evaluate the efficacy and safety of eltrombopag in patients with severe "acute" and persistent ITP within 6 months of diagnosis.
Methods: A multicentre, single arm open label study involving 39 patients with severe ITP (a) with platelet count of $<30x10^9$/L despite a daily dose of prednisolone of 1mg/kg for at least 2 weeks from diagnosis OR (b) requiring prednisolone ≥10mg daily and/or recurrent doses of IvIg to maintain a platelet of $\geq 30x10^9$/L within 6 months of diagnosis. Prior splenectomy was not a requisite.

Patients with platelets <10x10^9/L will commence on eltromobopag 75mg daily while those with a count ≥10x10^9/L will commence on 50mg daily. A reduced dose is used for subjects of East Asian heritage. The dose of eltrombopag can be progressively increased by 25mg increment every 2 weeks to maximum of 150mg daily (patients of East Asian heritage should have a maximum eltrombopag dose of 100mg daily) if the platelet count remains ≤30x109/L or there is clinically significant bleeding every 2 weeks. The steroid can be progressively weaned to zero over the subsequent 6 weeks if clinically appropriate. The primary endpoint was overall response rate (ORR) at week 12, defined as the proportion of patients achieving complete response (CR; platelet >100x10^9/L), partial response (PR; platelet >50 x10^9/L) or minor response (MR; platelet ≥30x10^9/L with ≥50% reduction in the dose intensity of concomitant ITP therapy compared with screening). The protocol specified a 1-sided 5% level binomial test of the null hypothesis that ORR at week 12 ≤30% and reporting of a 90% two-sided confidence interval (CI).
Results: Of the 39 patients enrolled, 46% were women, median (Q1, Q3) age was 52 (37, 68) years, median (Q1, Q3) time since ITP diagnosis was 2.2 (1.1, 5.4) months, and median (Q1, Q3) screening platelet count was 21(13, 34) x10^9/L. Prior treatments included steroids (95%), IVIG (58%), and immunosuppresion (28%). 35 patients (90%) completed 12 weeks of treatment, 4 (10%) discontinued eltrombopag prior to week 12 [3 required new ITP therapy; 1 developed pulmonary embolism (PE)]. The median (Q1, Q3) dose eltrombopag at week 12 was 50 (50, 100)mg daily. The median (Q1, Q3) dose of steroid at week 12, zero (0, 5)mg daily. At week 12, the ORR was 64% (p<0.0001; 90% CI: 51-77%); CR, PR, MR rates were 41%, 15% and 8% respectively and the median (Q1, Q3) platelet count among responders was 168 (98, 252)x10^9/L. At week 26, the ORR was 54% (90% CI 40-67%); CR, PR, MR rates were 28%, 21% and 5% respectively. Two patients had serious adverse events (SAEs) with two episodes of venous thromboembolism (one deep vein thrombosis at platelet 97x10^9/L; one pulmonary embolism at platelet 240x10^9/L). There were no other adverse events or deaths.
Summary/Conclusions: The majority of patients with ITP diagnosed for ≤6 months had a favourable overall response rate to eltrombopag and the drug was generally well tolerated. Longer-term follow up data (beyond 6 mos) will be presented at the meeting.

E1432

A NOVEL RUNX1 MUTATION IN FAMILY WITH FAMILIAL PLATELET DISORDER WITH PREDISPOSITION TO ACUTE MYELOGENOUS LEUKEMIA

L. Krupkova[1,*], M. Divoka[1], B. Ludikova[2], J. Kucerova[1], M. Holzerova[1], A. Hlusi[1], T. Szotkowski[1], T. Papajik[1], D. Pospisilova[2]
[1]Department of Hemato-oncology, [2]Department of Pediatrics, University Hospital and Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

Background: Familial platelet disorder with predisposition to acute myelogenous leukemia (FPD/AML) is a clinically heterogeneous group of rare disorders with autosomal dominant inheritance. Germline mutations in *RUNX1* were identified as causative lesions in several families with FPD/AML. *RUNX1* plays a key role in megakaryocyte maturation and differentiation but also in ploidization and platelet formation. In FPD/AML, *RUNX1* mutations are very heterogeneous and often specific to individual pedigrees, most commonly involving exons 3-5 in the RHD domain near the N-terminus of *RUNX1*. The presence of *RUNX1* mutation in FPD/AML is associated with 30-50% lifetime risk of developing AML. Clonal hematopoiesis can be detected in >80% of asymptomatic FPD/AML individuals at the age of 50.
Aims: To analyze mutational status of *RUNX1* and clinical and laboratory markers of the disease in family with hereditary thrombocytopenia including 3 cases of MDS/AML.
Methods: Platelet aggregation was measured on 4-channel aggregometer APACT 4004, with platelet rich plasma (PRP) in response to adenosine diphosphate (ADP), collagen, epinephrine and agglutination in the presence of ristocetin. DNA and RNA were isolated from peripheral blood leukocytes using standard procedures. Stored DNA from 2 patients who succumbed to AML was used for analysis. Mutational status of *RUNX1* was determined using direct Sanger sequencing of PCR products on DNA level. Analysis of alternative transcript length was performed using PCR with cDNA template, followed by detection on agarose gel electrophoresis. Sequences of alternative transcripts were obtained using direct Sanger sequencing. In 3 patients with MDS and/or AML, standard cytogenetics with G-banding was done, chromosomal changes were confirmed by fluorescent *in situ* hybridization (FISH).
Results: 9 individuals (4 adults, 5 children) from 3 generations in one family with FPD/AML were analysed. Novel hereditary *RUNX1* mutation NM_001754.4:c.509-13C>A was found in 7/9 family members as a likely cause of FPD/AML. The mutation is located in intron between exons 2 and 3 and disrupts RNA splicing, resulting in formation of alternative transcript with aberrant length (11 nucleotides longer than its physiological variant). Frameshift and premature termination of amino acid sequence presumably cause impaired function of the truncated protein. All family members harboring the mutation had various degree of thrombocytopenia (range 60-128x10^9/l) and did not require treatment in the absence of clinical bleeding. In 6/7 patients with mutation, decreased aggregation with collagen and epinephrine was found. Six of 7 patients with *RUNX1* mutation have iron deficiency anemia of unknown origin. Two women died of AML at the age of 51 and 38 years - the mother had karyotype 47,XX,+9[4]/46,XX[16] and her daughter harbored two pathological clones 45,XX,-7[5]/46,XX,-7,+8[3] and one clone with normal karyotype. The second daughter is followed due to pancytopenia with myelodysplastic changes, particularly marked megakaryocytic dysplasia with normal cytogenetics but severe aggregation impairment.
Summary/Conclusions: We revealed novel causal *RUNX1* mutation in familial thrombocytopenia. Identification of *RUNX1* mutation facilitates proper diagnosis of FPD/AML and identification of heterozygous carriers can help detect the development of myeloid malignancy. In the patient with pancytopenia, possible impact of other somatic mutations acquired during leukemogenesis will be examined.

PROFILING CIRCULATING MICRORNAS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP) TO EXPLORE THE ROLE OF MICRORNAS AND POSSIBLE BIOLOGICAL PATHWAYS INVOLVED IN THE PATHOGENESIS OF ITP

L. Garabet[1,2,3,*], W. Ghanima[1,4], A. Rangberg[1], R. Teruel-Montoya[5,6], C. Martinez[5], J.B. Bussel[7], P.M. Sandset[3,8], C. Monceyron Jonassen[1]
[1]Østfold Hospital Trust, Grålum, [2]Akershus University Hospital, Lørenskog, [3]Institute of Clinical Medicine, University of Oslo, [4]Department of Haematology, Oslo University Hospital, Oslo, Norway, [5]Hospital Universitario Morales Meseguer, [6]CB15/00055-CIBERER, Murcia, Spain, [7] New York Presbyterian Hospital, Weill Cornell Medical Center, New York, United States, [8]Department of Haematology, University Hospital of Oslo, Oslo, Norway

Background: MicroRNAs (miRNAs) are small noncoding RNAs involved in regulation of gene expression. Dysregulated expression of miRNAs has been associated with several autoimmune diseases. ITP is an autoimmune disease characterized by isolated thrombocytopenia and increased risk of bleeding. The development of autoantibodies against platelets and megakaryocytes results in increased platelet destruction and insufficient platelet production remains central to the pathophysiology of ITP. Platelets contain high levels of miRNAs and a substantial fraction of circulating miRNAs originates from platelets. Circulating miRNAs are stable and relatively easy to measure and considered as potential disease biomarkers. The role of miRNAs in the pathogenesis of ITP has not been well explored.
Aims: Determine the expression profile of circulating miRNAs in ITP patients in aim to identify miRNAs that can be used as disease biomarkers and to explore the potential biological pathways that might be involved in the pathogenesis of ITP.
Methods: Exiqon Serum/plasma Focus microRNA PCR panel was used to determine the expression profile of 179 miRNAs in plasma acquired from 8 ITP patients with low platelet count and who failed to respond to various treatment for ITP, and from 8 age- and sex-matched controls. In addition, next generation sequencing (NGS) for miRNAs was performed in 2 pooled plasma samples (pool 1 from 4 ITP patients, and pool 2 from 4 matched controls), on the Illumina NextSeq 500 system. Statistical analyses were performed with the GenEx software and SPSS. Pathway analysis was performed using DIANA-miRPath v3.0 to explore the probable pathways involved in the pathogenesis of ITP.
Results: Comparing the expression profiling from the PCR panel between ITP patients and matched controls, 81 circulating miRNAs were differentially expressed (p<0.05), of those 17 miRNAs had a high statistical significance (Bonferroni correction). Among those, miR-191-5p and miR-26a-5p were down-regulated and miR-486-5p and miR-222-3p were up-regulated in ITP compared to controls. Interestingly, 15 of the 17 differentially expressed miRNAs from PCR panel were also differentially expressed in NGS. Using the 17 differentially expressed miRNAs in the miRPath analysis, we uncovered some immune system related pathways, including MyD88-independent toll-like receptor signaling pathway and TRIF-dependent toll-like receptor signaling pathway, as enriched pathways in target genes of miRNAs differentially expressed between ITP patients and controls.
Summary/Conclusions: We identified a large number of miRNAs that were differentially expressed in ITP patients compared to controls that might be associated with the pathogenesis of ITP. Pathways analysis uncovered some possible biological pathways that might be involved in the pathogenesis of ITP. Further validation of these miRNAs in a larger patient cohort and preferably in comparison to patients with other causes of thrombocytopenia such as aplastic anemia to explore the role of these miRNAs in the pathogenesis of ITP. Future studies of these miRNAs in relation to initiation of treatment with defined clinical outcomes as treatment response/ remission after initiation of treatment will clarify their potential as biomarkers for treatment response.

NORDIC COUNTRY PATIENT REGISTRY FOR IMMUNE THROMBOCYTOPENIA (NCPRITP): A COHORT OF PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA IN DENMARK, SWEDEN, AND NORWAY

C. Christiansen[1], S. Bahmanyar[2], W. Ghanima[3,*], N. Kristensen[1], S. Stryker[4], J. Acquavella[1], K. Cetin[5], M. Nørgaard[1], H. Sørensen[1]
[1]Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [2]Clinical Epidemiology Unit & Center for Pharmacoepidemiology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Department of Medicine, Østfold Hospital Trust, Fredrikstad, Norway, [4]Center for Observational Research, Amgen Inc, San Francisco, [5]Center for Observational Research, Amgen Inc, Thousand Oaks, United States

Background: Immune thrombocytopenia (ITP) is a rare disease characterized by isolated low platelet counts and an increased tendency to bleed. As yet, there have been no large, multi-country, population-based cohorts established to describe its long-term clinical course and investigate the effectiveness and safety of related therapies.
Aims: To describe the establishment of the NCPRITP and the characteristics of patients enrolled.
Methods: Encompassing Denmark, Norway, and Sweden, the NCPRITP started as a population-based post-authorization safety study to assess the long-term safety of romiplostim in treating ITP. It includes patients with prevalent chronic ITP (cITP – ITP lasting >6 months) as of 04/01/2009 and incident cITP diagnosed from 04/01/2009-12/31/2014, confirmed through medical record review. Since the start of the registry, guidelines have changed to define cITP as ITP lasting >12 months. For consistency, incident cases of ITP for a duration of >6 months will continue to be accrued through 2019. Through linkage of data from the national health registries and medical record review, the registry has rich clinical information for all enrolled ITP patients, such as comorbidities (including scores according to the Charlson Comorbidity Index [CCI] – a validated tool developed to predict 1-year mortality), treatments, lab values (e.g., platelet counts), and complete follow-up for several clinical outcomes of interest (e.g., clinically significant bleeding, the need for rescue therapies, and thromboembolic/thrombotic events). Additionally, available bone marrow samples are restained and reexamined for reticulin and collagen content to assess Thiele´s myelofibrosis (MF) grading.
Results: The NCPRITP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50x10^9/L, 16% were splenectomized, and 41% had at least one previous ITP therapy (mainly oral glucocorticoid steroids). The majority (68%) of the cohort had no underlying conditions included in the CCI at study enrollment, but 8% had a CCI score of 3 or higher, indicating severe comorbidity. Of note, based on hospital diagnoses of specific comorbidities recorded within 5 years before study enrollment, 8% had a history of a solid tumor, 9% had a history of diabetes, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.
Summary/Conclusions: The NCPRITP provides an example of how, within the Nordic countries' uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

Background: Primary immune thrombocytopenia (ITP) is a rare disease. The incidence of ITP is not well estimated in Russia and worldwide. Due to WHO information it varies from 1,6 to 3,9/100 000 person-years in adults. The gender and age-associated results in Russia and abroad are discussed and differ in several investigations.
Aims: evaluation of the incidence and demographic characteristics of primary immune thrombocytopenia in adults in Russia.
Methods: The data source is the Registry of the patients with primary ITP in Russia (intermediate data during the 2 years period). 1063 adult patients: 254 males (24%) and 809 females (76%), age from 18 to 89 years (median 44 years) with ITP (ICD-10 code D69.3).
Results: 41 region of Russia participated in the Registry formation. In 2016 more than a half of patients (58%) in comparison with 2014 (201 persons) and 2015 (441 persons) entered the Registry. All patient's mean age at the moment of diagnostic was 47.2 years, in females - 47.6, in males – 45.9. The gender-age distribution was following: male: age <30=20% of cases, age 31-40=19%, age 41-50=12%, age 51-60=19%, age 61-70=22%, age >70=8%. Three regions of Russia (Republic of Crimea, Irkutsk and Tula Regions) were selected for assessment of the incidence of ITP because of fully performed registration process. The number of newly diagnosed cases in these regions was 31, 42 and 56 patients per year respectively. ITP incidence was 1.3/100 000 person-years in Republic of Crimea, 1.7/100 000 in Irkutsk Region and 3.7/100 000 in Tula Region. The gender-age distribution was following: male: age <40=37%, age 41-60=26%, age >60=37%; female: age <40=50%, age 41-60=25%, age >60=25%. Totally, the ITP incidence rate in females was three times higher than in male population. Among patients with chronic ITP (82% of the total number of patients) the disease duration distribution was following: up to 3 years - 50% of the total number of patients, 3-6 years – 18.7%, 7-10 years - 11.6%, >10 years - 19.7%. The mean disease duration was equal to 6.7 years.
Summary/Conclusions: Overall incidence of ITP in three selected regions of Russia is: 1.3/100 000 person-years in Republic of Crimea, 1.7/100 000 in Irkutsk Region and 3.7/100 000 in Tula Region. It is compatible to the incidence in other European countries. Variations in parameters could be due to geographic location or not fully performed registration process. Our data demonstrate the rise of incidence rate in males with age and its decrease in female population. The number of patients included in the study on the epidemiology of ITP increased 5 times during 2016 in comparison with 2014 and 2015. Geographical variations of incidence of ITP in different regions of Russia require further study.

ELTROMBOPAG (EPAG) FOR THE TREATMENT OF PATIENTS AGED ≥65 YEARS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP): SAFETY AND EFFICACY RESULTS FROM THE EXTEND STUDY

A. Salama[1,*], R.S. Wong[2], A. Khelif[3], M.N. Saleh[4], B. Meddeb[5], O. Ocak Arikan[6], E. Quebe-Fehling[6], J.B. Bussel[7]
[1]Charite-Universitätsmedizin, Berlin, Germany, [2]Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, Hong Kong, [3]Hôpital Farhat Hached, Sousse, Tunisia, [4]Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, United States, [5]Hôpital Aziza Othmana, Tunis, Tunisia, [6]Novartis Pharma AG, Basel, Switzerland, [7]Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States

Background: ITP is an acquired autoimmune disorder characterized by isolated platelet reduction, which is considered chronic when it persists for >12 months. Evidence suggests that age may influence both the hemorrhagic manifestations of ITP and also response and adverse events (AEs) associated with some therapies. Changes in drug metabolism can contribute to increased AE rates in patients (pts) ≥65 yrs compared with younger adults. The oral thrombopoietin-receptor agonist, EPAG, is approved for the treatment of previously treated (eg corticosteroids, immunoglobulins) cITP pts, but limited data are available in pts ≥65 yrs old. The EXTEND study was a global, open-label, extension study that evaluated long-term efficacy, safety and tolerability of EPAG in adults with cITP who had participated in prior EPAG studies.
Aims: To describe the efficacy, durability of response, and safety of EPAG use in pts with cITP aged ≥65 yrs.
Methods: All pts on EXTEND started EPAG at 50mg/day, titrated to 25–75mg/day or less often as required, based on individual platelet count responses: to achieve counts in the range ≥50–200×10^9/L. Maintenance dosing continued after minimization of concomitant ITP medication and optimization of EPAG dosing. Pts could remain on EPAG either for 2 yrs in countries where EPAG was commercially available, or for >2 yrs until EPAG became commercially available.
Results: At baseline (BL), 50/302 pts (17%) on EXTEND were ≥65 yrs old (mean ± SD 73±5 yrs). Among these 50 pts, 24% were splenectomized, 62% female and 74% had platelet counts <30×10^9/L. Twenty-four pts (48%) withdrew early from the study, most commonly because of AEs (n=8, 16%), other reasons (n=7, 14%) and lack of efficacy (n=5, 10%). Median exposure duration was 2.3 yrs (range, 2 days to 7.9 yrs) and mean daily dose was 49.9 (range, 11–75)mg/day. Overall, 43 (86%) pts achieved platelets ≥50×10^9/L without rescue therapy; 37 (74%) achieved platelets ≥50×10^9/L for ≥50% of assessments; 26 (52%) maintained platelet counts continuously ≥50×10^9/L for ≥22 weeks (Figure). Median time maintaining platelet counts >50×10^9/L and twice BL values,

while not receiving rescue treatment, was 78 (range, 0–350) weeks. Incidence of bleeding symptoms (WHO grades 1–4) decreased from BL (66%) to 1 yr (15%). AEs were reported in 47 (94%) pts, most frequently nasopharyngitis (n=13, 26%), constipation (n=12, 24%), fatigue (n=12, 24%), diarrhea, arthralgia, urinary tract infection, cataract and cough (all n=11, 22%). Serious AEs occurred in 24 (48%) pts, most frequently (>5%) cataracts (n=7, 14%), pneumonia (n=3, 6%) and urinary tract infection (n=3, 6%). The most frequent AEs with suspected relationship to study drug were cataracts (n=4, 8%), headache, fatigue, and increased ALT, AST and bilirubin (all n=3, 6%).

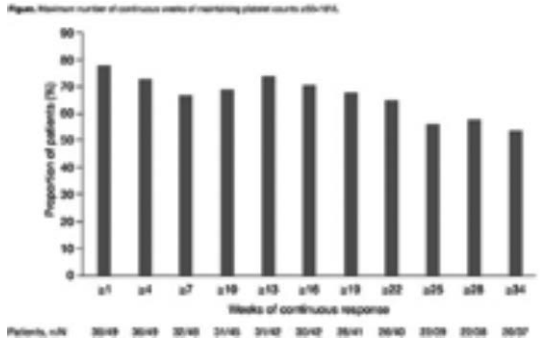

Figure 1.

Summary/Conclusions: The efficacy of EPAG in cITP pts ≥65 yrs was consistent with that seen with the overall EXTEND study population (Bussel *et al. Haematologica* 2016;101[s1];S517), with sustained platelet increases and reduced bleeding. EPAG was well tolerated; AE rates were similar to that reported in the overall EXTEND study population, but an apparent increase in cataracts was observed in pts ≥65 yrs old (cataract incidence was 7% and 22% in <65 and ≥65 age groups, respectively). Further outcomes in patients <65 yrs old will be presented. Results should be interpreted with caution as almost half of the pts withdrew from the study. EPAG is an effective treatment option for certain cITP pts ≥65 yrs; its use should incorporate baseline cataract screening and regular monitoring.

E1438

SAFETY AND EFFICACY OF THROMBOPOIETIN RECEPTOR AGONISTS IN PATIENTS WITH PREVIOUSLY TREATED CHRONIC IMMUNE THROMBOCYTOPENIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Yamada[1,*], T. Fujii[2], C. Cromwell[3], I. Shapira[3]
[1]Medicine, Mount Sinai Beth Israel, New York, [2]Internal Medicine, University of Hawaii, Honolulu, [3]Hematology, Mount Sinai Beth Israel, New York, United States

Background: The current American Society of Hematology guideline recommends the use of thrombopoietin receptor agonists, eltrombopag or romiplostim as one of the second-line therapies for chronic immune thrombocytopenia (ITP). The efficacy and safety of those drugs have been tested in several clinical trials. However, the safety profile was not consistent throughout trials and is not yet well understood.
Aims: We herein conducted a meta-analysis of randomized control trials to compare the safety and efficacy of thrombopoietin receptor agonists; eltrombopag and romiplostim *versus* placebo in patients with previously treated chronic ITP. Our primary outcome was drug-related adverse events greater than CTCAE grade 3.
Methods: We performed a literature search in MEDLINE, EMBASE, Cochrane library, and the American Society of Hematology website up to September, 2015 by two independent authors according to PRISMA guideline. We included only randomized clinical trials comparing eltrombopag or romiplostim *versus* placebo. Random-effects model was used to estimate pooled Odds Ratio (OR).
Results: A total of eight trials including 834 participants were included in the analysis. There was no significant difference of grade 3 or higher adverse events between placebo and treatment group (OR=1.01, CI 0.57-1.78). Thromboembolism (OR=0.59 CI 0.20-1.73), elevated ALT (OR=0.68 CI 0.26-1.74), headache (OR=1.26, CI 0.90-1.78), nausea (OR=0.82 CI 0.43-1.55), or fatigue (OR=1.13 CI 0.65-1.91) did not show a significant difference between groups, either. Clinical response, which is defined as platelets ≥50,000/μL at least once on treatment was significantly better in treatment group than in placebo group (OR=0.10 CI 0.07-0.15). Bleeding symptoms (WHO Grades 1-4) were significantly more frequent in the placebo group (OR=1.6, CI 1.14-2.24) during treatment.
Summary/Conclusions: Although several studies have suggested clinically significant treatment-related adverse events, such as thromboembolism, this meta-analysis showed that thrombopoietin receptor agonists are safe, well-tolerated, and effective in patients with previously treated chronic ITP.

E1439

CHILDHOOD IMMUNE THROMBOCYTOPENIA: A NATIONWIDE COHORT STUDY ON CONDITION MANAGEMENT AND OUTCOMES

N. Aladjidi [1], C. Nordon[2,*], G. Leverger [1], T. Leblanc [3], L. Grimaldi-Bensouda[2]
[1]CHU Bordeaux, Bordeaux, [2]LASER, [3]CHU Robert Debré, Paris, France

Background: Little is known about the management of pediatric ITP in real life, that is, routine clinical practice. Moreover, the predictive value of these factors upon disease outcome was explored individually and therefore the confounding effect of associated exposures remains unknown.
Aims: With this nationwide prospective cohort study, our objectives were to explore (1) the factors associated with treatment initiation (vs. watchful waiting) in children with primary immune thrombocytopenia (ITP) followed in routine clinical practice and (2) the predictors of chronicity at 12 months.
Methods: Between 2008 and 2013, 23 centers throughout France consecutively included 257 children aged 6 months to 18 years and diagnosed with primary ITP over a 5-year period. Data on ITP clinical features along with medical management were collected at baseline and 12 months. Multivariate logistic regressions were used to determine (1) and (2) as defined above, providing odds ratio (OR) with 95% confidence intervals (95%CI).
Results: 137 (53%) children were males, median age was 4.6 years, median platelet count was 7×109/L, and 214 (81%) patients initiated medication. Factors independently associated with treatment initiation included platelet counts <10x109/L (p<0.0001) and mucocutaneous bleeding symptoms at baseline (p<0.001). At 12 months, data were available in 211 (82%) children, of whom 160 (74%) had recovered. Predictors of chronicity included female gender (OR=2.2; 95% CI=1.0–4.8), age ≥10 years (OR=2.6; 95% CI=1.1–6.0) and platelet counts ≥10x10^9/L (OR=3.2; 95% CI=1.5–6.9).
Summary/Conclusions: In routine clinical practice, the decision to apply a watchful-waiting strategy seems to be driven by platelet counts even in the absence of bleeding symptoms, resulting in treatment being initiated in more than 80% of the children surveyed. Overall, younger children with ITP showed good prognosis, with lower platelet counts and, to a lesser extent, male gender predicting more favorable outcomes.

E1440

SIROLIMUS FOR THE TREATMENT OF CHILDREN WITH IMMUNE THROMBOCYTOPENIA AND EVANS SYNDROME. A SINGLE CENTRE EXPERIENCE

M. Miano[1,*], A. Rotulo[1], E. Palmisani[1], A. Grossi[2], F. Pierri[1], M. Calvillo[1], C. Micalizzi[1], P. Terranova[1], E. Cappelli[1], T. Lanza[1], M.T. Giaimo[1], I. Ceccherini[2], C. Dufour[1], F. Fioredda[1]
[1]Haematology Unit, [2]Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: The treatment of chronic/relapsing immune thrombocytopenia purpura (ITP) is not well established due to the lack of evidence-based data, and is particularly challenging in children who are more at risk of severe side-effects secondary to prolonged steroid therapies. Sirolimus has been shown to be effective in patients with ITP secondary to ALPS[1]and in very few patients with primary disease or secondary to ALPS-like syndromes[2].
Aims: The aim of this study is to evaluate the outcome and toxicity of patients with ITP either primary or secondary to ALPS-like syndromes, with or without involvement of other cell lineages.
Methods: We retrospectively evaluated charts of patients followed in our Unit for ITP primary or secondary to ALPS-like syndromes. Patients with ALPS were excluded. ALPS-like was defined as the presence of at least one absolute or primary additional criterion for ALPS. Complete response (CR) and partial response (PR) were defined as a platelet count >/= 100x10^9/L and >30x10^9/L and at least 2 fold increase of the baseline count, respectively.
Results: 23 children aged 0-12 yrs (median 6) with primary ITP (7) or secondary to an ALPS-like disorder (16), were treated with Sirolimus. Seven patients (30%) with ALPS-like also had an Evans syndrome (ES), due to the association of leukopenia (1), or to the presence of trilinear cytopenia (6). Four patients with ALPS-like were found to have mutations on PI3KCD, CTLA4, TACI, and CARD 11 gene. All patients, but one treated in first-line, received Sirolimus as second (4), third (14) or fourth (4) line treatment, respectively. 18 patients had previously failed Micofenolatemofetile (MMF) therapy. Overall, 17/23 (74%) patients achieved a response that was complete and partial in 12 (52%) and 5 (22%) cases, respectively. Patients with ES responded in 6/7 (86%) cases. Children with mono-linear ITP achieved a response in 11/16 (68%) cases, in particular 4/7 (57%) and 7/9 (77%) patients with primitive or secondary disease, respectively. 12 out of 18 (66%) patients who failed MMF therapy responded to Sirolimus rescue. Three patients (13%) reported toxicity consisting of ovary cysts (2) and gastrointestinal issues (1) that required the interruption of the treatment in 2 cases.
Summary/Conclusions: To the best of our knowledge this is the largest cohort of patients with ITP or ES -other than ALPS -treated with Sirolimus, that showed to be safe and effective in most cases, including patients who previously failed

MMF treatment. Therefore, it can be considered as an alternative therapeutic option in the setting of ITP non only for patients with an underlying diagnosis of ALPS but also for the ones with primitive disease or with an ALPS-like disorder.

ASSESSMENT OF ROMIPLOSTIM SELF-ADMINISTRATION BY PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA AND CAREGIVERS FOLLOWING RECEIPT OF HOME ADMINISTRATION TRAINING (HAT) MATERIALS: A CROSS-SECTIONAL STUDY

M. Schipperus[1,*], G. Kaiafa[2], L. Taylor[3], S. Wetten[4], J. Bennett[4], G. Kreuzbauer[5], A. Boshier[6], A. Seesaghur[4]
[1]Department of Haematology, Haga Teaching Hospital, The Hague, Netherlands, [2]AHEPA University Hospital, Thessaloniki, Greece, [3]Royal London Hospital, London, [4]Amgen Limited, London (Uxbridge), United Kingdom, [5]Amgen (Europe), Zug, Switzerland, [6]Amgen Limited, Cambridge, United Kingdom

Background: A HAT pack was designed as an additional risk minimization tool to support healthcare providers (HCPs) in selecting patients and training of patients/caregivers to mitigate medication error risk when self-administering romiplostim subcutaneously, a thrombopoietin-receptor agonist which is approved in the European Union (EU) to treat chronic immune thrombocytopenic purpura (ITP) refractory to other treatments.
Aims: To estimate the proportion of adult patients and caregivers who administered romiplostim correctly after HAT pack training.
Methods: This non-interventional, cross-sectional study enrolled 40 patients/caregivers and was conducted at 12 centres in Austria, Belgium, France, Germany, Greece, The Netherlands, Spain, and The United Kingdom, from 7 July 2014 to 20 November 2015. HCPs directly observed adults (≥18 years of age) with chronic ITP or caregivers new to administering romiplostim in the act of product administration at the first standard-of-care (SoC) 4-week visit after HAT pack training. Correct administration of romiplostim (primary endpoint) was defined as dose accuracy within 10% margin of error between prescribed and administered romiplostim doses, and correct romiplostim reconstitution and successful injection, and no HCP intervention during administration to correct patient/caregiver error. All analyses were descriptive and no formal hypothesis was tested.
Results: At the first SoC visit, 4 weeks (range: 2-8 weeks) after HAT pack training, 35 patients/caregivers (87.5%) administered romiplostim correctly. The dose accuracy was within 10% margin of error for all patients. HCP intervention was required in 5 instances: 1 patient did not ensure all romiplostim was dissolved, 1 patient and 1 caregiver needed verbal encouragement, 1 patient needed nursing intervention to read the correct dose from the vial due to poor eyesight, and 1 caregiver needed guidance with syringe and vial connection. Further follow-up data was available for only 2 of these 5 patients/caregivers; they both administered romiplostim correctly at a voluntary subsequent visit.
Summary/Conclusions: Given that this study was conducted on a convenience instead of random sample of patients, generalizability of the results may be limited. Direct observation can be susceptible to observation bias and to the Hawthorne effect with the patients/caregivers acting differently when observed. Nonetheless, the success of most patients and caregivers in correctly administering romiplostim after HAT pack training suggests that self-administration of romiplostim is a feasible option for suitable romiplostim-treated ITP patients.

E1442

FCΓIIA 131 H/R (A>G) RECEPTOR GENE POLYMORPHISM IN PATIENTS OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)

A. Tripathi[1,*], D. Yadav[1], A. Kumar[2]
[1]Clinical Hematology, [2]K.G. Medical University Lucknow India, Lucknow, India

Background: Primary Immune Thrombocytopenia (ITP) is an autoimmune hematologic disorder characterized by isolated thrombocytopenia (<100,000/cmm) in the absence of other causes or disorders that may be associated with thrombocytopenia. The predominant mechanism is enhanced peripheral destruction of autoantibody coated platelets through binding of Fc portion of antibody with the Fcγ receptors on cells of reticuloendothelial system mainly monocytes/macrophages.
Aims: This study was aimed to investigate the association of polymorphisms in *FcγIIA 131 H/R* (A>G) gene with Primary Immune thrombocytopenia (ITP).
Methods: Genotyping for the *FcγIIA 131 H/R* (A>G) was performed using polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP) in 70 ITP patients and 70 healthy controls.
Results: The mean age of patients and control was 29.53± 13.86 yrs and 27.90± 8.89 yrs respectively. Male/Female ratio in patients and control was 1:2. Under additive model, the heterozygous genotype (AG) of the *FcγIIA 131 H/R* (A>G) polymorphism shows the significant association with ITP, (Odds Ratio 2.41 (95% CI, Lower - 1.19 Upper 4.90 *P*- value 0.0149) whereas the homozygous mutant genotype (GG) had no significant association with ITP (Odds Ratio 2.47 (95% CI, Lower - 0.63 Upper 9.72 with *P*- value 0.2979). Under dominant model, the Odds Ratio was 2.42 (95% CI, Lower - 0.34 Upper 0.94) with the significant *P*- value 0.0167. Mutant allele (G) frequency was 37.85% in patients and 25.71% in controls (Odds ratio 1.76 1.05-2.93 with the p-value 0.0397).
Summary/Conclusions: The study shows the association of heterozygous genotype (AG) of *FcγIIA 131 H/R* (A>G) with ITP. The dominant model also shows significant association with ITP. We conclude that mutant allele (G) in *FcγIIA 131 H/R* (A>G) gene polymorphism may have impact on susceptibility to ITP.

E1443

SHORT- AND LONG-TERM RESULTS OF FIRST LINE THERAPY WITH PULSED HIGH-DOSE DEXAMETHASONE IN ADULT IMMUNE THROMBOCYTOPENIA PATIENTS: A RETROSPECTIVE SINGLE-CENTER REPORT

L. Crucitti[1,*], S. Cantoni[1], R. Cairoli[1]
[1]Hematology and Oncology, Niguarda Cancer Center, Ospedale Niguarda Ca' Granda, Milano, Italy

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder mediated by clearance of antibody-opsonized platelets (plt) by spleen macrophages. Pulsed high-dose dexamethasone (HD-DXM) has proved to be effective in adult patients (pts) with primary ITP resulting in controlled studies in 89% short-term response and a relapse-free survival (RFS) of 58% at 50 months (mos) (Mazzucconi, Blood 2007).
Aims: To assess the short-term and sustained response rates of adult ITP pts receiving pulsed HD-DXM in everyday clinical practice.
Methods: Charts of pts with ITP - as defined by Rodeghiero, Blood 2009 - treated with HD-DXM were reviewed. DXM was administered according to the schedule of 40mg/day for 4 consecutive days to be repeated every 21 days for a maximum of 6 courses. A reduced-dose schedule of 20mg/day for 4 days was preferred for elderly/diabetic pts. Pts who had completed at least 3 courses were included in the analysis. Response to HD-DXM was classified according to IWP definitions (Provan, Blood 2010); therefore, steroid-dependent pts were considered as non-responders even if plt counts increased to safe levels during HD-DXM and were included only in the analysis of short-term response, but not evaluated for long-term response. Short-term response rate was determined at completion of the whole course of treatment. Relapse was defined as a plt count decrease ≤20x10^9/L after initial response achievement and RFS was defined as the time interval between last course administered and the date of relapse, censoring pts alive or dead without relapse. Follow-up was defined as the time between diagnosis and last available assessment. The probability of RFS was calculated using the Kaplan-Meier method.

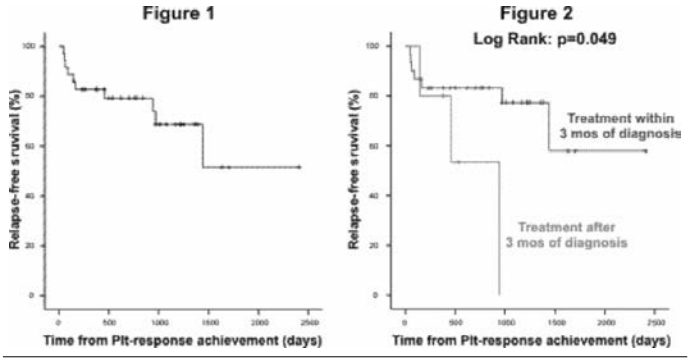

Figure 1.

Results: A total of 45 pts (M: 21) were eligible for analysis; median age at treatment was 60 yrs (range 18-87) and median time between diagnosis and treatment start was 3 days (range 0-4686). Pts received a median of 5,15 courses (range 3-6); 27/45 completed 6 courses: 21/45 received the full dose of 40mg/day (=960mg total dose) while 6/45 received the reduced dose of 20mg/day (=480mg total dose). Median total DXM dose was 800mg; IVIG along with 1st DXM course were required in 11/45 pts. In between courses, no bleeding complications were observed and no emergency therapies were required. Short-term response was achieved in 39/45 (87%): complete response (CR) in 28/45 (62%), response (R) in 7/45 (16%); 4/45 (9%) pts were classified as steroid-dependent ITP and excluded from subsequent analysis. Long-term response off therapy, lasting for a median time of 28 mos (range 5-80) without relapses was observed in 25/35 responding pts (71.5%; CR in 18/25, R in 7/25 at last follow-up) with a RFS of 51% at 50 mos (Fig. 1). Median plt count at last

follow-up was 192x10^9/L (range 54-336). Disease duration of less than 3 mos prior to therapy start was associated with better outcome (log rank p=0.049, Fig.2) with a median RFS not reached; median RFS for pts treated after 3 mos of diagnosis was 31 mos [OR: 3.8 (CI 95% 0.9-16.3), p=0.067]. No significant association between gender (p=0.67), age at treatment (more or less than 60 yrs) (p=0.85), DTX total dose (more or less than 480mg) (p=0.35) was found.
Summary/Conclusions: Pulsed HD-DXM is a well tolerated and highly effective first line treatment for ITP in every day clinical practice. The role of a reduced-dose schedule needs to be explored in a larger cohort of pts. Treatment of newly diagnosed ITP pts - *i.e.* within 3 mos of diagnosis (Rodeghiero Blood 2007) - seems to lead to longer RFS.

E1444

EFFECT OF OSELTAMIVIR TREATMENT ON PLATELET COUNTS

N. Revilla[1,*], I. Heras[2], M.E. de la Morena-Barrio[3], P. Iniesta[2], J.B. Nieto[2], J. Corral[3], V. Vicente[3], M.L. Lozano[3]
[1]Servicio de Hematología y Oncología Médica, [2]Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, [3]Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca. Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: As platelets lose sialic acid during aging and circulation, they are cleared by the hepatic Ashwell-Morell receptor (AMR) (1). A recent study suggests that inhibition of sialidase by oseltamivir, a commonly administered anti-influenza medication that inhibits viral sialidase, could associate with an increase in platelet counts (2).
Aims: The aim of this study was to analyze the effect of oseltamivir treatment in platelet counts.
Methods: We performed a retrospective single-center study. From November 2009 until March 2015, a total of 168 patients from our Hematology Unit were prescribed oseltamivir due to clinical suspicion of influenza. A total of 120 patients were excluded because they had received myelotoxic chemotherapy within 30 days (n=82) or platelet count was not available before treatment (n=38). The direct immunofluorescent antigen test was carried out with nasopharyngeal aspirate specimens. Those specimens that were negative by the antigen detection assay underwent RT-PCR testing for influenza virus types A and B. Platelet count was available before and after treatment (median of 5 days) in 48 patients and in 44 patients also when the infection was cleared (median of 30 days).
Results: Patients were divided into those with proven influenza (n=34) and without influenza (n=14). Median age was 58.0 and 59.5 years; respectively. Treatment consisted of 75mg oseltamivir bid for 5 days, with the exception of 3 patients in the proven influenza group receiving 150mg bid for 10 days (allogeneic stem cell transplant recipients). We observed a significant increase in the mean platelet count after treatment with oseltamivir (170±95 x10^9/L *vs* 190±103 x10^9/L, p=0.04). As in the previous study (2), this effect was independent of whether influenza was diagnosed (Table 1). In addition, we did not discern significant fluctuation in platelet counts when treatment was immediately interrupted or after a 30-day time lapse (184±100 x10^9/L *vs* 182±91 x10^9/L).

Table 1.

Table 1. Platelet counts (x10^9/L) in patients with a clinical suspicion of influenza before and after oseltamivir treatment (median of 5 days). Results are given as mean and standard error.

Influenza positive (n=34)		Influenza negative (n=14)	
Before: 156 +/- 92	After: 174 +/- 99	Before: 203 +/- 94	After: 228 +/- 107
p=0,139		p=0,158	

Summary/Conclusions: Our study confirms the effect of oseltamivir on increasing platelet counts regardless of influenza infection. Although an increase in platelet counts related to the viral syndrome healing is not ruled out, the lack of long-term fluctuations after the end of treatment may indicate a late inhibition that contributes to reduction in platelet clearance via the hepatic receptor.

E1445

CLINICAL UTILITY OF CARDIAC MRI IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA

F. Alwan[1,*], D. Mahdi[1], S. Mc Guckin[1], J. P. Westwood[1], M. Thomas[1], J. Moon[2], M. Scully[1]
[1]Haematology Department, University College London Hospital, [2]Cardiac Imaging Department, Barts Heart Centre, London, United Kingdom

Background: Immune Mediated Thrombotic Thrombocytopenic Purpura (TTP) is a life threatening thrombomicroangiopathy caused by acquired antibody mediated inhibition of ADAMTS13. Cardiac complications are a common cause of death and a raised troponin is a recognized risk factor for poor prognosis in TTP. There is scant evidence on the best investigations for patients suspected of being at risk of cardiac complications with no evidence on the clinical utility of cardiac magnetic resonance imaging (MRI) in acute TTP episodes.
Aims: A retrospective review evaluating the value of cardiac MRI scanning in TTP.
Methods: 24 patients underwent cardiac MRI scanning between September 2008 and November 2014 whilst being treated for an acute episode of immune mediated TTP. All patients had troponin-t measurement on admission and a transthoracic echocardiogram within 72 hours of presentation. All patients were treated for their TTP episode with plasmapheresis, steroids and Rituximab. Two cardiologists reported each MRI scan and only agreed, unequivocal findings were considered.
Results: The median age of patients was 49 (range 13-75), 71% of whom were women. Two patients had a diagnosis of hypercholesterolemia prior to TTP diagnosis but otherwise there was no previous cardiac history. 71% of patients had a raised troponin-t at presentation (normal <14ng/ml). Two patients developed bradycardia and one atrial fibrillation during their acute admission. One patient had symptoms of heart failure. Three patients had transient ST depression suggestive of ischemia on EKG monitoring and a further four had non-specific T-wave inversion. There were no incidences of cardiogenic shock or ST elevation myocardial infarction. 33% of patients (n=8) had abnormal cardiac MRI results. Late gadolinium enhancement (LGE) in the mid-apical regions, a finding suggestive of focal myocardial fibrosis and usually secondary to myocardial necrosis, was seen in all 8 patients, subendocardial LGE in six, transmural LGE in one and one patient had both subendocardial and transmural LGE. The latter patient was the only one with any abnormality seen on the preceding transthoracic echocardiogram. LGE seen in combination with regional wall motion abnormalities (RWMA) suggests irreversible myocardial dysfunction. No patient was found to have RWMA on transthoracic echocardiogram but this was seen in five patients on cardiac MRI imaging, all of whom also had LGE. The median troponin-t was not significantly higher in those with an abnormal cardiac MRI (normal MRI 100ng/ml, abnormal MRI 165ng/ml, p=0.9), nor was there a significant difference in median age (49 *vs* 49), symptom duration (abnormal MRI 7 days, normal 5 days, p=0.39) or presenting anti-ADAMTS13 antibody level (abnormal MRI 41%, normal MRI 40%, p=0.66).
Summary/Conclusions: Cardiac MRI scanning in TTP is a sensitive tool for detecting ischemic cardiac changes that would otherwise be missed by transthoracic echocardiogram. Mid-Apical late gadolinium enhancement appears to be a characteristic finding in TTP. These findings help increase the understanding of the pathophysiology behind the TTP disease process

E1446

THE FREQUENCY AND CLINICAL SIGNIFICANCE OF MEFV GENE MUTATIONS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

I. Kaygusuz Atagunduz[1,*], C. Keklikkiran[2], T. Toptas[1], O. Kara[1], A. Sezgin[1], F. Gecgel[1], T. Ozgumus[1], T. Firatli Tuglular[1]
[1]Hematology, [2]Internal Medicine, Marmara University Hospital, Istanbul, Turkey

Background: Immune thrombocytopenia (ITP) is an immune-mediated acquired disease characterized by transient or persistent decrease of the platelet counts. MEFV gene mutations are responsible for Familial Mediterranean Fever (FMF) a hereditary autoinflammatory disease characterized by recurrent febrile inflammatory attacks of serosal and synovial membranes. MEFV gene's protein product, pyrin or marenostrin, play an essential role in the regulation of inflammatory reactions. MEFV gene mutations are associated with a wide range of auto-inflammatory and autoimmune diseases. Recently, studies showed that MEFV mutations change the Th1, Th2 balance and increase the Th17 numbers. Th17 cells may have a key role in neutrophil activation and autoimmune diseases. ITP is an autoimmune-mediated condition that results from antibody-mediated destruction of platelets and impaired megakaryocyte platelet production. ITP is a complex disorder of immune dysregulation caused by anti-platelet antibodies produced by B cells. A recently proposed model for ITP involves antigen-presenting cells, B cells and T cells. Increased Th1/Th2 ratio and Th17 levels are implicated in the pathogenesis of ITP, as well.
Aims: This study addressed the prevalence of MEFV mutations and their effect on clinical features of ITP.
Methods: We studied the prevalence of exon 2 and 10 mutations (E148Q in exon 2, M694V, M694I, M680I, V726A, A744S and R761H in exon 10) in 81 adult ITP patients and 186 healthy controls. Patients were classified in two subgroups according to the presence of mutations. Demographic and clinical features were compared between groups to assess possible impacts of these mutations on clinical severity.
Results: Female to male ratio was 61/20=3,05 in the study group and 98/88=1,1 in the control group. The median age was 50 (21-79) in the ITP

group and 56 (24-76) in the control group. Overall MEFV mutation prevalence was%25.9 (21/81) in the study group and%24.7(46/186)in the control group, (p=0.963). MEFV mutation distribution prevalence was similar in both gender groups among ITP patients and their presence did not alter the age of disease onset, (p>0,05). Similarly, presence of mutations did not change the platelet count at diagnosis, the number of treatment courses, the rate of patients undergoing splenectomy and primary steroid resistance. Although statistically not significant, there was a trend towards a better overall response to steroids in patients carrying MEFV mutations,%94.7 *vs*%82.8,(p=0,28) respectively. The median time to loss of response to steroids was 60 (10-124) months in patients with mutations and 42 (19.2-64.8) months in patients without MEFV mutations, (p=0.64). The median time to splenectomy was 101 (42.5- 159.5) months in the MEFV mutation carriers and 51 (46-56) months in the non-carriers, (p=0.48). Time to loss of response to splenectomy was 38 (12-90.9) months in mutation carriers and 54 (14.9-93.1) months in non-carriers,(p=0.42).

Summary/Conclusions: To the best of our knowledge, our study is the first to address a possible effect of MEFV mutations on ITP. MEFV mutation carrier rates were similar in both ITP and control groups. Although MEFV carrier state had no affect on clinical features of ITP, mutation carriers tended to have a better overall response to steroid treatment, stayed longer in remission, had a longer time to splenectomy and relapsed earlier after splenectomy.

E1447

PD-1 AND CTLA-4 POLYMORPHISMS AFFECT THE SUSCEPTIBILITY AND CLINICAL FEATURES OF CHRONIC IMMUNE THROMBOCYTOPENIA

R. Ino[1,*], T. Kasamatsu[1], Y. Kitamura[1], K. Honma[1], T. Nagashima[1], N. Takahashi[2], N. Gotoh[1], M. Takizawa[3], A. Yokohama[4], H. Handa[3], T. Saitoh[1], H. Murakami[1]
[1]Department of Laboratory Sciences, Gunma University Graduate School of Health Sciences, [2]Gunma University, [3]Department of Hematology, [4]Blood Transfusion Service, Gunma University Hospital, Maebashi, Gunma, Japan

Background: The programmed death-1 (PD-1) and cytotoxic T lymphocyte-associated antigen-4 (CTLA-4) play a central role in immune checkpoint pathways. The PD-1 negatively regulates self-reactive T and B cells in peripheral immune tolerance. The CTLA-4 antagonizes the binding of CD28 to its ligands including CD80 and CD86, and inhibits T cell activation. Previous studies have shown the lower expression of serum soluble PD-1 and CTLA-4 mRNA in patients with chronic immune thrombocytopenia (cITP) than healthy individuals. Single nucleotide polymorphisms (SNPs) of PD-1 and CTLA-4 have been reported to be associated with susceptibility of some autoimmune diseases; however, the possible association between these immune checkpoint SNPs and cITP risk remain controversial and obscure.

Aims: In order to explore the role of PD-1 and CTLA-4 in the pathogenesis of cITP, we investigated the impact of PD-1 and CTLA-4 SNPs on the susceptibility and clinical features of adult cITP.

Methods: We extracted the genomic DNA from 141 cITP patients and 223 healthy controls, and determined, 3 PD-1 SNPs (-606G/A, +7209C/T, A215V) and 4 CTLA-4 SNPs (-1722T/C, -1577G/A, +49A/G, +6230G/A) by using the polymerase chain reaction -restriction fragment length polymorphism (PCR-RFLP) method. The severity of bleeding tendency and thrombocytopenia was assessed according to the previously described criteria by Han JJ. The response criteria, 'corticosteroid dependence','severe cITP', and 'refractory cITP' were assessed according to the criteria of the ITP International Working Group. The characteristics and laboratory data of cITP patients with CTLA-4 and PD-1 polymorphisms were compared by using the Mann-Whitney U test for continuous variables and the chi-square test for categorical variables. This study was approved by the Institutional Review Board of Gunma University Hospital (Approval #160007).

Results: The minimum platelet count of all clinical course ranged from 0 to 98×10^9/L with a median count of 13×10^9/L. Eighty-six patients (61.0%) had bleeding tendency and 24 patients (17.0%) had severe thrombocytopenia (< 10×10^9/L). Eighty-six patients (61.0%) received the treatment with corticosteroid, and 38 patients (27.0%) were corticosteroid-dependent. As compared to healthy controls, the higher frequency of PD-1 +7209 TT genotype (low producer) was observed in cITP patients (12.8% *vs* 4.5%, p=0.004). There were no significant differences in CTLA-4 SNPs between cITP patients and healthy controls. In cITP patients, PD-1 +7209 TT genotypes (low producer) was significantly associated with high frequency of treated patients, treated patients with coticosteroid, and steroid-dependent patients compared with CC & CT genotype (high producer) (94.4% *vs* 71.5%, 94.4% *vs* 57.7% and 52.9% *vs* 23.6%; p=0.043, 0.003 and 0.018, respectively). On the other hand, CTLA-4 +49 AA genotype (high producer) was significantly associated with low bleeding tendency than AG & GG genotype (low producer) (36.4% *vs* 65.5%, p=0.010). CTLA-4 +6230 AA genotypes (high producer) was significantly associated with low bleeding tendency than AG & GG genotype (low producer) (27.3% *vs* 63.8%, p=0.017). CTLA-4 -1577 AA genotypes (high producer) was significantly associated with low frequency of bleeding tendency and steroid treatment than AG & GG genotype (low producer) (20.0% *vs* 64.1% and 30.0% *vs* 64.9%; p=0.014 and 0.041, respectively). CTLA-4 -1577 AA genotypes was significantly associated with higher minimum platelet count than AG & GG genotype (22.5 *vs* 14.0 $\times10^9$/L, p=0.048).

Summary/Conclusions: Our findings indicate that PD-1 gene polymorphisms contribute to the susceptibility of cITP, and PD-1 low producer genotype affects the severity of cITP. In addition, CTLA-4 high producer genotypes suggest the good clinical features and a little requirement of treatment in patients with cITP.

E1448

IS THE SPLENECTOMY OUTCOME PREDICTABLE IN PATIENTS WITH ITP?

M. Mitrovic[1,2,*], S. Matic[2,3], J. Bodrozic[1], M. Smiljanic[1], J. Jelicic[1], D. Antic[1,2], M. Todorovic - Tirnanic[2,4], D. Tomin[1,2], I. Elezovic[1,2], N. Suvajdzic[1,2]
[1]Clinic of Hematology, CCS, [2]Faculty of Medicine, University of Belgrade, [3]Clinic for Digestive Surgery, [4]Center for Nuclear Medicine CCS, Belgrade, Serbia

Background: Splenectomy may lead to a good response in 60-80% of adults with corticosteroid refractory immune thrombocytopenia (ITP). However, in the era of new drugs the proper selection of patients for splenectomy is essential to optimizing treatment outcomes. Accordingly, it is important to identify pre- or post-operative parameters that are able to predict the response to splenectomy.

Aims: To identify the pre- and postoperative parameters predictive of successful splenectomy in ITP.

Methods: We retrospectively analyzed 130 ITP patients (median age 43 years, range 19-74; 84/39 female/male; median time from diagnosis to splenectomy 19 months, range 2-132; median number of pre-splenectomy therapies 2, range 1-5; median follow-up from splenectomy 112 months, range 2-364) who underwent splenectomy between the years 1986 and 2015.Platelet kinetic study with Indium-111 was performed in 50 patients before splenectomy. Indications for splenectomy were: unresponsiveness to initial corticosteroid therapy, need for continuous glucocorticoid therapy to maintain safeplatelet counts and multiple relapses after discontinuing corticosteroids.Complete response (CR) and partial response (PR) were defined as platelet count (PC) $>100\times10^9$/L and 30×10^9/L one month after surgery, respectively. The patient was considered refractory if his PC remained $<30\times10^9$/L after splenectomy. Relapse was defined as a loss of CR or PR.

Results: CR and PR were achieved in 105/130 (79%) and 12/130 (7.5%) of the splenectomised patients, respectively. However, 13/130 (112.5%) patients were refractory. Twenty-nine of the 117 (24.8%) responsive patients relapsed. Predictors of good response after splenectomy identified by univariate analysis were: initial response to steroids (69.5% *vs* 22.7%, τ=0.358, p<0.0001), higher PC on the surgery day (90×10^9/L vs.37×10^9/L, ρ=0.353, p<0.0001), on the first (387×259/L *vs* 56×109/L, ρ=0.502, p<0.0001) and on the 7thdays after splenectomy (387×25^9/L vs.25×10^9/L, ρ=0.522, p<0.0001) and splenic platelet destruction (86% *vs* 0%, τ=0.358, p=0.0001). Using ROC analysis, cut-off prognostic values of PC were reevaluated: PC before splenectomy $>47x10^9$/L (AUC 0.864, sensitivity 63.6%, specificity 83.2%, 95% CI 0.785-0.943, p<0.0001), PC on the first day after splenectomy $>50x10^9$/L (AUC 0.956, sensitivity 44.4%, specificity 83.2%, 95% CI 0.912-0.999, p<0.0001) and PCon the 7thday after splenectomy $>300x10^9$/L (AUC 0.951, sensitivity 91.7%, specificity 45.6%, 95% CI 0.873-1.000, p<0.0001). By multivariate analysis, splenic platelet destruction, PC $>47x10^9$/L on the day of surgery (p=0.043) and PC $>300x10^9$/L on the 7thday after splenectomy (p=0.0013) were identified as predictive for favorable response. Patients who relapsed frequently were older >60 years (31% *vs* 23%,p=0.030) and had lower PC three months after splenectomy ($130x10^9$/L *vs* $278x10^9$/L, ρ=0.203, p<0.0001). However, ROC values could not be calculated.

Summary/Conclusions: Splenectomy is effective in approximately two thirds of patients with ITP. Our study suggests that splenectomy might be considered in the patients younger than 60 years, with splenic platelet destruction and PC $>50x10^9$/L on the splenectomy day.

E1449

FINAL RESULTS FROM AN OBSERVATIONAL STUDY (PLATEAU) OF ADULT PATIENTS TREATED WITH ROMIPLOSTIM FOR PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN ROUTINE CLINICAL PRACTICE IN GERMANY

M. Reiser[1,*], M. Welslau[2], K. Josten[3], H. Dietzfelbinger[4], A. Kuhn[5]
[1]PIOH Koeln, Koeln, [2]Gemeinschaftspraxis Dr. Klausmann, Dr. Welslau, Aschaffenburg, [3]Hämatologie und Onkologie, Helios Kliniken Praxis, Wiesbaden, [4]Haematologisch-onkologische Schwerpunktpraxis, Herrsching, [5]Amgen GmbH, München, Germany

Background: In the European Union, the thrombopoietin-receptor agonist romiplostim (Nplate®) is recommended since January 2016 for treatment of ITP in adult patients who are refractory to other treatments (*e.g.* corticoids, immunoglobulins).

Aims: The aim of this study was to assess the use of romiplostim in clinical practice in Germany.

Methods: This multicentre, prospective and retrospective observational study (data collected before and after initiation of romiplostim) enrolled ITP patients ≥18 years who received at least one dose of romiplostim in routine clinical practice, with an observation period of 2 years following romiplostim initiation. Endpoints included patient demographics, romiplostim use, platelet counts, adverse

drug reactions (ADRs), and other clinically relevant parameters. We report results from a full data set analysis.
Results: A total of 59 patients were enrolled (49.4% male; 54% aged 65 years or above) from 38 sites; 22 of them were excluded due to protocol violations (*e.g.* incomplete documentation, inclusion criteria not met). Of the 137 remaining patients (the full analysis set, FAS), 102 completed the 2-year observation period. Reasons for dropping out included loss to follow-up (10 patients), deaths (6 patients) and ADRs (3 patients). Median (Q1, Q3) time from ITP diagnosis to romiplostim initiation was 21.7 months (4-85) months in the FAS. 123 FAS patients received prior ITP therapies; most of them received corticosteroids (104 [75.9%]). 117 patients (85.4%) were non-splenectomized before romiplostim therapy, for reasons such as refusal of splenectomy, comorbidities, or age. Over the observation period, romiplostim was injected at a median (Q1, Q3) dose of 3.11 mcg/kg/bw (1.8 – 4.8; FAS) over a median (Q1-Q3) treatment period of 103 weeks (33-104). The median platelet count rose sharply from baseline (29.0 x 10^9/L) to two weeks of treatment (62.5 x 10^9/L). From week 3 to two years of follow-up, the median count remained in a range between 87.5 x 10^9/L and 145.5 x 10^9/L. Since the start of romiplostim therapy, 59 patients out of 137 (43.1%) received concomitant therapies, mostly corticosteroids (49 patients [35.8%]). The overall number of ADRs was 112 in the FAS, affecting 37 patients (27.0%). The most frequent ADRs were gastrointestinal (10.2%) and neurological (11.7%) ADRs, followed by constitutional symptoms (10.9%). Adverse drug reactions pertaining to blood/bone marrow affected 2.9% of patients (vascular/thrombotic events, bone marrow fibrosis), whereas bleeding as an ADR was seen in 0.7% of patients. The exposure-adjusted rate of bleeding events (grade 3 or 4) per 100 patient-years in the FAS was 7.2 before treatment initiation *vs*. 4.0 after starting the treatment. The rate of ITP-related hospitalization per 100 patient-years decreased from 23.3 before the start of therapy to 15.5 since the start of therapy.
Summary/Conclusions: This study of routine clinical practice in Germany showed that treatment with romiplostim in ITP patients resulted in a rapid increase in platelet counts to levels maintained between 50 and 250 x 10^9/L over time, regardless of the splenectomy status of the patients; most of them were non-splenectomized. The product was well tolerated and achieved a decrease in the rate of ITP-related hospitalization.

E1450

THE CLINICAL UTILITY OF NEUROPSYCHOLOGY TESTING IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA
F. Alwan[1,*], S. Tayabali[1], D. Mahdi[1], M. Thomas[1], J.P. Westwood[1], L. Cipolotti[2], M. Scully[1]
[1]Haematology Department, University College London Hospital, [2]Neuropsychology Department, National Hospital for Neurology and Neurosurgery, London, United Kingdom

Background: It is well recognized that neurological manifestations are common in thrombotic Thrombocytopenic Purpura (TTP) however research into the neuropsychological impact of the disease is lacking despite evidence suggesting patients who experience critical illnesses are at high risk for long-term cognitive impairment.
Aims: To review the clinical utility of neuropsychology testing in thrombocytic thrombocytopenic purpura.
Methods: Between 2010 and 2015, all patients within a single tertiary hematology center with a confirmed diagnosis of TTP were reviewed as outpatients after their acute episode. Those with persisting, non-physical neurological or psychological symptoms underwent cerebral MRI scanning and were referred for neuropsychological assessment. The Wechsler Adult Intelligence Scale III (WAIS-III) IQ test was used to assess factors including verbal IQ and performance IQs.
Results: 18 patients were included. 89% were female with a median age of 51 (16-67 years). 56% were Caucasian, 33% Afro-Caribbean and 11% of South Asian ethnic origin. 33% had experienced TIA or stroke-like symptoms during their acute TTP episode whilst 28% had no neurological symptoms during their initial presentation. The most common symptom leading to neuropsychology review was problems with concentration, experienced by 89% of patients. 44% had problems with memory, 39% felt depressed and 33% had anxiety issues. The median time from acute TTP episode to neuropsychology review was 29 months (range: 3-99 months). 25% had normal cerebral MRI scans, 50% had signs of sub-acute infarction on imaging and two patients scans showed both mature infarcts and microhaemorrhages. The median scores for both verbal and performance IQs were reduced compared to average (normal 100, range 90-110). The median verbal IQ was 87 (range: 65-122) and the median performance IQ 83 (range: 56-109). Taking all aspects of the WAIS-III review into consideration, one patient had a normal assessment. 50% (n=9) were found to have mild cognitive impairment, 33% (n=6) mild-moderate impairment and 11% (n=2) significant impairment. The two cases with significant impairment had a widespread pattern of dysfunction whilst in the other cases the most common pattern was of anterior/sub-cortical involvement (44%).
Summary/Conclusions: Persisting psychological symptoms after an acute TTP episode are highly suggestive of underlying cognitive impairment as a result of cerebral sub-acute infarction or microhaemorrhages.

E1451

FIVE NEW CASES OF HERMANSKY-PUDLAK SYNDROME: IDENTIFICATION OF NOVEL GENETIC VARIANTS IN HPS4 AND HPS3 ASSOCIATED TO RELEVANT CLINICAL COMPLICATIONS
J. Bastida[1,*], J. Gonzalez-Porras[1], M. Lozano[2], R. Benito[3], K. Janusz[3], N. Bermejo[4], M. Karkukak[5], M. Trapero[6], M. del Rey[3], Y. Yucel[5], J. Hernandez-Sanchez[3], V. Palma-Barquero[2], V. Vicente[2], J. Hernandez-Rivas[3], J. Rivera[2]
[1]Department of Hematology, Hospital Universitario de Salamanca-IBSAL, Salamanca, [2]Department of Hematology and Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER,, Murcia, [3]Department of Hematology, IBSAL, IBMCC, CIC, Universidad de Salamanca-CSIC, Salamanca, [4]Department of Hematology, Hospital San Pedro de Alcántara, Caceres, Spain, [5]Department of Medical Genetic, Sakarya University Training and Research Hospital, Sakarya, Turkey, [6]Department of Hematology, Hospital Universitario Puerta de Hierro, Majadahonda, Spain

Background: Hermansky-Pudlak syndrome (HPS) is an inherited platelet disorder characterized by bleeding diathesis, oculocutaneous albinism and sometimes serious clinical complications. Heterogeneous clinical symptoms and a large numbers of possible genetic culprits (9 *HPS* genes, >118 exons) complicate unequivocal HPS diagnosis.
Aims: To assess the clinical and platelet phenotype in five patients with HPS suspicion and to identify their genetic defect by high-throughput sequencing (HTS).
Methods: We studied 5 patients from 3 families (2 Spanish, 1 Turkish) presenting with oculocutaneous albinism. Clinical records were reviewed and bleeding scored with ISTH-BAT. Platelet phenotyping (only Spanish patients) included: platelet aggregation, GPs expression and granule secretion, ^{14}C-serotonin uptake and whole mount electron microscopy. Patients DNAs were analyzed by HTS using a 71 gene panel.
Results: Clinical and laboratory findings in these patients are shown in Table 1. The Spanish patients (P1,P2,P5) showed impaired platelet aggregation to mild agonists and reduced platelet dense granules. In family 1 (F1), HTS identified a homozygous, potentially harmful, c.2054delC (p.Pro685Leu fs*17) variant in *HPS4.* One sister (P1) had Crohn´s disease and severe gastrointestinal (GI) bleeding. This variant had been reported in a 46yr Asian patient with pulmonary fibrosis (Bachli EB. Am J Med Genet 2004). *A* novel missense homozygous *HPS4* variant, c.272T>C (p.Leu91Pro), was found in two Turkish siblings (F2). One had severe GI bleeding requiring colectomy (P4) and the other developed pulmonary fibrosis. Patient 5, suffering from mild GI bleeding, bears a heterozygous novel variant in *HPS3* (c.2464C>T, p.Arg822X) and, most likely, an additional unrevealed mutation.

Table 1.

Family	Patients	Bleeding Symptoms	Other clinical features	ISTH-BAT	Light Transmission Aggregometry	Flow cytometry	14C-Serotonin Uptake	Electron microcopy	Molecular variants
1	P1: 13y, female P2:16y, female No Familial Consanguinity	P1+P2: Epistaxis, ecchymosis, menorrhagia P1: GI, and post-surgery	P1+P2: oculocutaneous (OC) albinism P1: Crohn's disease	P1: 11 P2: 3	Impaired aggregation with ADP (5mM), epinephrine (5mM) and ristocetin (1.2 mg/mL)	P1+P2: TRAP-induced CD63 release: 10% Plts+ vs. 65% in control	25% reduction in ^{14}C-Serotonin uptake	Absence of dense granules	*HPS4* c.2054del (p.Pro685Leu fs*17)
2	P3: 40y, female P4:48y, female Familial Consanguinity	P3+P4: easy bruising and epistaxis. P3: GI bleeding	P1+P2: OC albinism and nistagmus. P3: Colectomy P4. Bilateral pulmonary fibrosis	P3:7 P4:6	-	-	-	-	*HPS4* c.272T>C p.Leu91Pro
3	P5:25y, male No Familial Consanguinity	Epistaxis, ecchymosis and GI	OC albinism and strabismus Angiodysplasias	P5: 5	Mildly impaired aggregation epinephrine (5mM) and ristocetin (1.2 mg/mL)	TRAP-induced CD63 release: 1% Plts+ vs. 60% in control	75% reduction in ^{14}C-Serotonin uptake	Reduced number of dense granules	*HPS3* c.2464C>T (p.Arg822X)

Summary/Conclusions: HTS facilitates genetic confirmation of HPS diagnosis, and may help investigating phenotype-genotype relationships in HPS. The novel p.Leu91Pro variant in *HPS4* associates with severe clinical phenotype.

E1452

CHARACTERIZATION OF PLATELET ACTIVATION MARKERS IN EARLY ONSET PREECLAMPSIA
D. Angelov[1,2,*], K. Egan[1,2], F. Ní Ainle[1,2,3,4,5]
[1]UCD Conway SPHERE Research Group, [2]School of Medicine, University College Dublin, [3]Department of Haematology, Rotunda Hospital, [4]Department of Haematology, Mater Misericordiae University Hospital, [5]School of Biomolecular and Biomedical Sciences, University College Dublin, Dublin, Ireland

Background: Preeclampsia is a serious pregnancy complication with potentially life-threatening consequences for both mother and baby, diagnosed when new onset hypertension and proteinuria develops after 20 weeks gestation. Early onset preeclampsia (EOP; onset <34 gestational weeks), is associated with higher maternal and fetal risks than late onset preeclampsia. At the extreme end of the severity spectrum, HELLP syndrome is characterised by

hemolysis, elevated liver enzymes, and low platelets. Previous studies have demonstrated enhanced platelet activation in pregnant women with pre-eclampsia, using cell surface markers and platelet microparticles[1]. Although severe pre-eclampsia is associated with increased inflammatory markers in vitro, levels of platelet activation do not necessarily correlate with severity of disease[2].
Aims: To assess the presence, and degree, of platelet activation in a cohort of patients with early onset preeclampsia (EOP)±HELLP syndrome, and to correlate this with evidence of *in vivo* coagulation activation using D-dimers.
Methods: Plasma samples from patients with EOP were accessed from a clinical biobank. Platelet activation markers were characterized using ELISA assays measuring platelet factor 4 (PF4), soluble glycoprotein VI (sGPVI) and neutrophil activating peptide-2 (NAP-2). Platelet microparticles ($CD42a^+$ microparticles) were measured by flow cytometry. Platelet activation biomarker levels were adjusted by platelet count and expressed as $/10^8$ platelets/ml). All data was analysed using GraphPad Prism 7. Parameters were reported as mean±SEM.
Results: Plasma samples from 19 individual patients were included. Patients with HELLP syndrome demonstrated significantly greater numbers of $CD42a^+$ microparticles when corrected for platelet count compared with those without HELLP syndrome ($598x10^3±203x10^3$ *versus* $297x10^3±37x10^3$, CD42a + microparticles/10^8 platelets/ml p=0.04). Similarly, patients with HELLP syndrome demonstrated increased levels of sGPVI than those without HELLP, corrected for platelet count (2.576±0.9667 *versus* 1.22±0.124 ng/ 10^8platelets/ml, p=0.0334). There was no difference in NAP-2 or PF4 levels between those with HELLP and those without HELLP, nor between severe and moderate pre-eclampsia patients. Severe pre-eclampsia patients in this cohort had a D-dimer level of 3.71±0.7742 µg/ml compared with non-severe patients 1.852±0.3501 µg/ml, p=0.0537. There was a significant correlation between sGPVI levels and D-dimer levels (Spearmann Rank correlation coefficient, r =0.532, p=0.04).
Summary/Conclusions: The results of this study demonstrate a positive correlation between severity of pre-eclampsia and platelet activation, as measured by levels of platelet-derived microparticles and platelet GPVI expression. A number of randomised controlled trials have evaluated the role of low-dose aspirin therapy as prevention for pre-eclampsia, and there is Grade 2B evidence for its use in those at risk of severe pre-eclampsia[3]. The evidence of enhanced platelet activation in our study provides rationale for the efficacy of aspirin in this setting, and the potential for novel antiplatelet agents to be studied for the same indication.

E1453

PRIMARY ITP IN ADULTS TREATED WITH ELTROMBOPAG: A RETROSPECTIVE STUDY USING DATA FROM THE UNITED KINGDOM ADULT IMMUNE THROMBOCYTOPENIA REGISTRY.

D. Provan[1,*], U. Doobaree[1], A. Newland[1], J. Fleming[2]
[1]Haematology, Barts and The London School of Medicine and Dentistry, London, [2]Haematology, Novartis, Camberley, Surrey, United Kingdom

Background: Primary ITP is an autoimmune disorder associated with a reduced peripheral blood platelet count. Although many patients are relatively asymptomatic, many suffer with bruising, mucosal bleeding and quality of life issues. The first line treatment has remained unchanged for decades and until recently, second-line therapy has been unsatisfactory, using empirical treatments. The recently approved thrombopoietin receptor agonists eltrombopag and romiplostim have transformed patient care and these agents are licensed second-line therapies in adults.
Aims: To describe the adult patients receiving eltrombopag using data from the UK Adult ITP Registry. In particular we were interested in understanding the mean dose used, number of prior therapies, median length of treatment with eltrombopag, median counts at baseline before treatment and at six months following treatment, and sustained response in patients who have received eltrombopag.
Methods: The UK Adult ITP Registry involved more than 70 UK collaborating centres, coordinated by The Royal London Hospital. In this study we analysed data from all patients receiving eltrombopag and analysed these using various statistical techniques.
Results: The total number of patients evaluable was 129. The median age at diagnosis was 49.4 years (26.9-66.4). There were 74 males (57.4%) and 55 females (42.6%). 29 patients (22.4%) had undergone prior splenectomy. The median age at eltrombopag initiation was 59.5 years (37.0-70.7 years). The median time from ITP diagnosis to eltrombopag initiation was 1.6 years (0.7-2.3 years). The majority of patients started eltrombopag between 2013 and 2016 (93%). 10 (8%) and 8 (6%) started eltrombopag within the first 6 months and between 6 to 12 months of ITP diagnosis, respectively. Most patients had received prior ITP therapies. Some 10 patients (7.8%) had received one prior ITP therapy and 99 patients (77%) had received three or more prior therapies before starting eltrombopag. The commonest prior therapies were corticosteroids in 110 patients (87%); IVIg 91 patients (72%); rituximab 68 patients (54%); romiplostim 47 patients (37%); and immunosuppressants 71 patients (56%). At baseline, prior to starting eltrombopag, the median platelet count was $21×10^9$/L (10-54) and the majority of patients (64.5%) had platelets less than $30×10^9$/L. The mean platelet count at 6 months was $206.2×10^9$/L and at 1 year was $288×10^9$/L. The median dose of eltrombopag used was 50mg/day. The median course length on eltrombopag was 14.7 (IQR: 4, 67) weeks. After initiation, 53 (41%) remained on eltrombopag as a monotherapy whereas 27 (21%) had other ITP treatment concurrently with eltrombopag. Forty nine (38%) changed treatment after eltrombopag, of which prednisolone (47%), IVIg (33%), mycophenolate (18%) and rituximab (14%) were the commonest and 10% underwent a splenectomy. Response to eltrombopag was assessed for 106 patients with adequate follow up time and platelet counts. 81 (76%) had a response, of which 54(51%) were above 100x109/L and 27 (25%) had a partial response (platelet counts between 30 to 100x109/L). Among those that had a response, 15 (14%) became unresponsive after some time whereas 2 (2%) patients were unresponsive soon after a brief episode of response. In short, 64 (60%) had a sustained response to eltrombopag (among patients who remained or came off eltrombopag).
Summary/Conclusions: The patient characteristics of those receiving eltrombopag appear to be typical of adult ITP. Only 10 patients (7.8%) received eltrombopag as a second line therapy. Three quarters had received 3 or more prior therapies before starting eltrombopag despite its licence as a second line therapy. As clinicians become more familiar with its use, a greater proportion of patients are likely to receive eltrombopag as a second line therapy.

E1454

EFFICACY OF TPO-MIMETICS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

F. Bacchiarri[1,*], V. Carrai[1], C. Biagiotti[1], A. Bosi[1]
[1]Hematology, AOU Careggi, Firenze, Italy

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune disorder in which antibodies are produced to circulating platelets. The two currently available agents (Romiplostim and Eltrombopag) have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.
Aims: We evaluated the efficacy of TPO-RAs in patients with ITP.
Methods: From November 2008 and February 2017 65 patients (33 M; 32 F) were treated with a median follow-up of 29 months (1-96): 39 underwent therapy with Romiplostim and 26 to Eltrombopag. Median age was 69 years (range 39-94 years). In the group of patients treated with Romiplostim, 21 had already received more than 4 lines of therapy, while 18 received 1-2 lines of therapy. 13/26 patients who received Eltrombopag were at the 3nd line of therapy, 1 at the second, and the others were at least at the 4th line. The median platelet count was $21x10^9$/L (3-52) at the start of Romiplostim, with a median starting dose of 1 µg (1-2) and $17x10^9$/L (1-53) in patients treated with Eltrombopag, with a median starting dose of 50mg (25-50).
Results: Patients treated with Romiplostim we observed 22 complete responses and 10 responses, with a 82% response rate, while 7 patients were no responders. In our study 26 (66%) patients stopped Romiplostim after a median time of 16 months (1-93): 9 for stable response, 5 for no response, 3 for loss of response; 3 for adverse events (2 for bone marrow fibrosis, 1 for headache associated to visual disturbances and gastrointestinal disorders), 2 underwent splenectomy, and 3 patients interrupted the treatment for other causes (es. diagnosis of cancer). The median platelet count at suspension of Romiplostim was 91.5 $x10^9$/L (3-320). In patients treated with Eltrombopag 16 achieved a complete response, 5 a response, obtaining response in the 80% of cases; 5 were no responders. 14 (53%) patients stopped Eltrombopag after a median time of 1,5 months (1-12): 6 for adverse events (2 cases of major cardiovascular events, liver toxicity, skin rash, pharyngitis), 5 for no response, 1 for loss of response, 2 patients who achieved a CR interrupted Eltrombopag obtaining a sustained remission after discontinuation. The median platelet count at suspension was $97x10^9$/L (2-739). Patients who did not interrupted treatment are still receiving therapy with a median of 29 months (3-96). Several studies reported Romiplostim and Eltrombopag to be highly effective against chronic ITP, with average immediate responses exceeding 80% in our study. We observed that therapeutic response was influenced by the starting platelet count. In particular platelets count before therapy influenced the first response observed. In particular in patients treated with Romiplostim PLT pre-treatment directly correlated with the first response and the mantainance of response during treatment at month 1°, 2° 3° and 6. Patients with a median starting platelet count of $15×10^9$/L obtained a response (CR + R), while almost all patients who started therapy with PLT<$15×10^9$/L at baseline can obtain an initial response, but the majority is non-responder.
Summary/Conclusions: TPO-mimetics have proved efficacy in patient with ITP and their use can be applied in several conditions (bridge to splenectomy; sustained response; switch and discontinuation). Future study on large series of patients are needed to best correlate baseline platelets with hematological response. The two currently available agents (Romiplostim and Eltrombopag) have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.

E1455

PREVALENCE AND RISK FACTORS FOR THROMBOSIS IN ADULT ITP PATIENTS

C. Moret[1], A. Tichelli[2], A. Wieland-Greguare-Sander[3], A. Angelillo-Scherrer[3], A. Rovó[3,*]
[1]Faculty of Medicine, University of Bern, Bern, [2]University Hospital of Basel, Basel, [3]University Hospital of Bern, Bern, Switzerland

Background: Immune thrombocytopenia (ITP) is characterized by severe thrombocytopenia due to autoantibody- and cell-mediated peripheral platelet destruction and attenuated thrombopoiesis. Despite a higher risk for bleeding, thromboembolic events (TEE) have been observed.
Aims: We aimed to investigate the prevalence and type of TEE and the potential risk factors in adult ITP patients.
Methods: Retrospective cohort study, including all ITP patients followed in our clinic between 01/1990 and 05/2016. Information on gender, age, date of ITP diagnosis, platelets count, type and clinical form of ITP, type of ITP treatments and its response, severe bleeding and follow up time were collected. Furthermore we evaluated date of first appearance, number and type of thromboembolic events, cardiovascular risk factors, date and cause of death. We assessed and compared risk factors of ITP patients with and without TEE in univariate and multivariate analysis.
Results: Medical files of 480 patients registered as ITP were reviewed; 42 patients were excluded from the analysis (not fulfilling the ITP criteria according to Rodeghiero *et al.* Blood 2009). In total 438 patients were retained for analysis, 10% out of them (44 patients) presented ≥1 TEE after ITP diagnosis. Within these patients, in total 54 TEE occurred: 34 venous (61%), 19 arterial (34%) and 3 arterial and venous (5%) thrombotic events. The most frequent venous TEE were pulmonary embolism, deep vein thrombosis, and superficial vein thrombosis; arterial TEE were cerebrovascular insults, myocardial infarction and peripheral artery thrombosis. At time of TEE, 43% of patients were on treatment with corticosteroids, 14% with thrombopoietin receptor agonists (TPO-ra) and 18% were off-treatment. In the univariate analysis, older age at diagnosis (≥50 years, P=0.015), longer interval since ITP diagnosis (P=0.001), persistent or chronic ITP (versus acute, P=0.009), ≥2 treatment lines (P=0.0002), TPO-ra at time of thrombosis (P=0.027), non-response to first-line treatment (P=0.010), smoking (P=0.011), arterial hypertension (P=0.005), and obesity (P=0.041) revealed to be significant. The multivariate analysis model showed that older age at diagnosis (RR, 2.272; 95% CI, 1.167-4.426; P=0.016), ≥2 treatments (RR, 2.539; 95%CI, 1.305-4.941; P=0.006), persistent or chronic ITP (RR, 3.830; 95% CI, 1.111-13.196; P=0.033), and smoking (RR, 2.622; 95% CI, 1.250-5.499; P=0.011 were independent risk factors for TEE. When the variable "number of treatments" (<2 *versus* ≥2) was excluded from the multivariate model, having a splenectomy increased the risk for TEE. The cumulative incidence of TEE at year 1, 5, 10, 15 and 20 years since diagnosis of ITP was 6.2% (95% CI, 4.1-9.3), 11.9% (95% CI, 8.3-17.0), 15.8% (95% CI, 11.1-22.4), 24.2% (95% CI, 16.9-34.7) and 32.8% (95% CI, 22.8-47.3) respectively (Figure). Death occurred in 7/44 (16%) patients with TEE, and in 12/394 (3%) patients without TEE (P=<0001). Most frequent causes of death were infection (32%) and bleeding (21%).

Figure: Cumulative incidence of thromboembolic events with 95% confidence interval

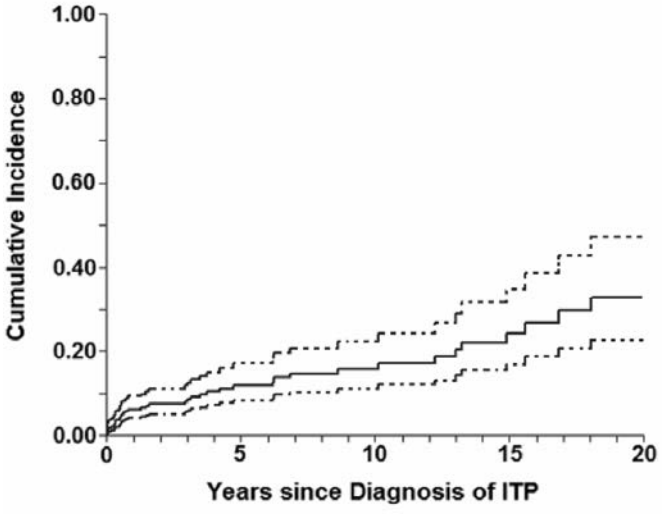

Figure 1.

Summary/Conclusions: Adult ITP patients are at risk for thromboembolic events. Patients older than 50 years, having a persistent/chronic form of the disease, requiring two or more lines to treat the ITP, previous splenectomy, and smokers were more likely to develop TEE. The knowledge about the risk of thromboembolic events in adults ITP patients could have an impact on management attitude for patients at risk.

E1456

OSELTAMIVIR FOR THE TREATMENT OF ITP PATIENTS NOT RESPONDING TO CONVENTIONAL TREATMENT: BIOLOGICAL CHARACTERIZATION AND CLINICAL RESPONSES

N. Revilla[1,*], R.M. Campos[2], F. Velasco[3], A. Miñano[4], I. Fuentes[5], J. Rivera[6], I. Martínez-Martínez[6], M.E. de la Morena-Barrio[6], J. Corral[6], V. Vicente[6], M.L. Lozano[6]

Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: Oseltamivir phosphate, a drug that conventionally serves as an antiviral sialidase inhibitor classically prescribed for the treatment of patients with influenza, has shown to induce an increase in platelet counts in 2 patients with primary immune thrombocytopenia (ITP) (1,2). A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance in ITP patients with anti-Glycoprotein (GP) Ibα autoantibodies (3). However, little is known about the exact response mechanism of this drug in ITP.
Aims: To analyze the biological features and clinical responses following oseltamivir treatment in patients that are non-responders to conventional treatments.

Table 1.

Table 1. Patients' characteristics

	ITP with NO response to oseltamivir (N=2)		ITP with response to oseltamivir (N=2)	
Age(y) Median (range)	78.5 (78-79)		49.5 (32-67)	
Sex (male/female)	1/1		0/2	
Splenectomized	0%		50%	
Previous treatment:	- Steroids + IVIG - Steroids, Eltrombopag		-Steroids + IVIG -Steroids+IVIG+Romiplostim	
Platelet count (x10^9/L) before and after OT Mean ± standard error	Before	After	Before	After
	3	8	3	134
	16	13	0	101
RCA-1 expression in patient platelets before OT (ratio)	3.08 (2.88-3.28)		6.97 (5.65-8.29)	
Decrease in RCA-1 expression in patient platelets after OT (ratio)	1.40 (1.19-1.60)		5.61 (4.76-6.45)	
RCA-1 expression in control platelets, patient sera, before OT (ratio)	1.05 (0.86-1.24)		2.76 (2.40-3.12)	
Platelet autoantibody specificity	Anti-IIb/IIIa (100%)		Anti-Ibα (100%)	

RCA-1 (which indicate loss of sialic acids of terminal glycans) data are expressed as fold change from control samples. Abbreviations: IVIG, immunoglobulins; OT, oseltamivir treatment.

Methods: We performed a prospective study in 4 ITP patients who exhibited no response to standard therapies (steroid, IVIG and/or splenectomy) and showing relevant platelet desialylation levels. Patients were given off-label oseltamivir at the referring physician´s discretion. Desialylation of GP platelet surface was examined via flow cytometry (FC) analysis, with fluorescein-conjugated *Ricinus Communis* Agglutinin I (RCA-1), which binds galactose residues only if the terminal sialic acid has been removed. FC data are expressed as fold change compared to control samples. Additionally, patients' sera were incubated with normal human platelets to analyze the ability to induce desialylation of normal platelets. Analysis of plasma proteins was performed by Western blot (FXI, FXII) and HPLC (transferrin). Platelet autoantibody specificity was detected by a solid-phase modified antigen capture ELISA test (MACE).
Results: Patients' characteristics are summarized in Table 1. Two patients achieved complete platelet response (>100x10^9/L) after oseltamivir treatment. The oral dose was 75mg twice daily, for a variable duration (5 days in one case and 4 months in the other showing response criteria since the third week of from start) combined with low doses of other treatments (azathioprine or romiplostim). A sustained platelet response was observed after 4 weeks of the sial-

idase inhibitor discontinuation. Patients with no response after oseltamivir treatment (n=2) were given similar doses for 5 days. Patients with response had antibodies directed solely to GPIb and had greater platelet loss of sialic acids. Moreover, their sera induced significant desialylation of normal platelets. However, no desialylation in patients' plasma proteins was detected. Biological analysis after treatment discontinuation (median of 3 weeks), revealed a sustained sialylation level of platelet glycoproteins over time, particularly in patients with sustained platelet response.
Summary/Conclusions: Chronic ITP patient with anti-GPIbα autoantibodies who do not respond to conventional therapies and exhibit significant platelet desialylation may achieve a complete response to treatment with oseltamivir.

BORTEZOMIB THERAPY IS ASSOCIATED WITH SIGNIFICANT RESOURCE IMPLICATIONS FOR BOTH PATIENTS AND PROVIDERS: RESULTS OF A TIME-IN-MOTION STUDY
M. Tatarczuch[1], K. Ramasamy[1], A. Peniket[1,*], M. Sultanova[1], G. Vallance[1], F. Panitsas[1]
[1]Haematology, Oxford University Hospitals NHS Trust, Oxford, United Kingdom

Background: Bortezomib is a proteasome-inhibitor, which has improved outcomes in multiple myeloma (MM). Its use is approved within the UK NHS. Bortezomib is frequently administered as a subcutaneous injection in a hospital day treatment unit. Whilst the administration of a subcutaneous injection is brief, the process for the patient travelling to hospital, assessment and waiting for the delivery of the injection can take considerable time. From a patient perspective, significant amount of time spent without economic activity and travel costs add up during the course of therapy. From the health-care provider the process of safely administering bortezomib has significant resource implications beyond those of drug procurement.
Aims: We set up a time-in-motion study to evaluate the costs to health care provider and patients during bortezomib therapy to estimate the 'real-world' cost of delivering bortezomib therapy.
Methods: Retrospective data collection was undertaken, using electronic prescribing records for patients treated between July 2014 -August 2016. Travel distance and time was estimated using Google maps and costed using HMRC mileage (an approved costing of mileage used for taxation purposes). The NHS schedule of service costs was used to estimate the cost of bortezomib administration. Cost of delivery of Bortezomib for healthcare providers is a sum of these individual costs.
Results: We identified 127 patients who incurred a total of 2 134 visits whilst receiving Bortezomib therapy at the Churchill Hosptial in Oxford during this 2 year period. Median age was 70 years-old (yo) (39-95); Male 74 patients (58%) 53 patients (42%). We restricted the analysis to 110 patients who started and completed therapy during the study period. Median number of patient visits was 16 (range 11-52). The median travel distance (return journey) for each patient was 33 miles (53 km) (range: 1.2-224 mi; 1.9-360 km). Median travel time was 90 min (range: 8-300 min). The range travel cost per patient was £8.35-£13.20. Twenty-seven patients (21%) required use of specialist hospital transport services, which resulted in 295 transport-episodes (14%) in total. In order to assess the time spent in the day therapy unit, a subgroup of 589 patient-episodes were analysed to assess time from arrival to administration of Bortezomib: the median time from patient registration to bortezomib administration was 63min (range: 5-433min). Pharmacy cost for preparation of Bortezomib was £50 per dose. The cost of delivery of bortezomib (not including cost of drug) was £1,160 per cycle, which equated to a total median cost of £4,640 per patient (range: £290-£15,080). Drug procurement costs for Bortezomib is estimated at an additional £12,261 per course of therapy (BNF 2016). Delivery costs therefore added an additional 38% to the procurement costs.
Summary/Conclusions: We provide the first time-in-motion data on myeloma patients treated with Bortezomib. The 'real-world cost' of delivering therapy is 37% higher than the drug-costs alone. In addition the impact on patients is substantial: over a two year period 127 patients required 2 134 visits with a median time in the day unit of 63 minutes and a median travel time of 90 minutes per visit. Our data highlights the burden of both time and economic costs to patients during therapy. Novel oral proteasome inhibitors offer the potential to reduce this resource impact in the future. This data could be used by health care providers and reimbursing agents for economic modeling of the potential benefits of oral proteasome inhibitors.

HOSPITAL CARE AT HOME ADMINISTRATION OF SUBCUTANEOUS AZACITIDINE IS FEASIBLE AND PREFERRED BY PATIENTS COMPARED TO HOSPITAL ADMINISTRATION: A FRENCH REGIONAL HEMATOLOGY NETWORK EXPERIENCE
M. Touati[1,2,*], M.P. Gourin[1], S. Moreau[1], S. Lefort[3], E. Bellet-Fraysse[4], C. Brillat[5], M. Jacquet[6], G. Maillan[7], A. Daulange[8], I. Joussain[9], L. Jeannet[2], Z. Boutalbi[1], E. Dumond Wibaux[2], D. Bordessoule[1], A. Jaccard[1]
[1]Service d'Hématologie Clinique et Thérapie Cellulaire, [2]Réseau Hématolim, Centre Hospitalier Universitaire, Limoges, [3]Oncologie et Radiothérapie, Centre Hospitalier, Brive-la-Gaillarde, [4]Service d'Hospitalisation à Domicile, Centre Hospitalier Universitaire, Limoges, [5]Service d'Hospitalisation à Domicile, Relai Santé Oncorèse, Brive-la-Gaillarde, [6]Service d'Hospitalisation à Domicile, Santé Service Limousin, [7]Pharmacie Centrale, Centre hospitalier Universitaire, Limoges, [8]Pharmacie Centrale, Centre Hospitalier, Brive-la-Gaillarde, [9]Service d'Hospitalisation à Domicile, CRFF 23, Noth, France

Background: In France, azacitidine (AZA) is indicated for the treatment of adult patients affected by Myelodysplastic Syndrome with intermediate-2 or high risk according to the International Prognostic Scoring System (IPSS), Chronic Myelomonocytic Leukemia (CMML) with 10-29% medullary blasts and Acute Myeloblastic Leukemia (AML) with 20-30% blasts. It's also a drug treatment of adult AML patients over 65 years with>30% of medullary blasts. Azacitidine is a hypomethylating agent administered by subcutaneous route. Though effective, treatment cycles require frequent hospital visits which could decrease patient comfort and increase medical personnel workload. Limousin is a region with the oldest population of France and with a very low population density. There is one university hospital and two local state-run hospitals each with a hematology department. In 2009, HEMATOLIM, the Limousin hematology network, set up a protocol called ESCADHEM (externalization and securitization of injectable chemotherapy at home for malignant hematological diseases) that facilitates chemotherapy administration via local Hospital at Home (HaH) establishments, which is an alternative to conventional hospitalization in France (www.fnehad.fr). The aim was to minimize the frequent hospital visits that these treatments require. This organization includes the three previously mentioned hospitals, four HaH structures, and three central pharmacies with an integrated preparation unit for cancer treatments. From 2009 to 2015, a total of 11 367 infusions were administred at home for 464 pts. In 2016, we demonstrated the feasibility of ESCADHEM and the medico-economic interest of such care with Bortezomib, another injectable chemotherapy at home (Touati *et al.* Support Care Cancer. 2016 Dec; 24(12):5007-5014). In 2014, we have conducted a satisfaction survey with a cohort of 84 pts who received treatment in HaH structures via ESCADHEM (20% pts with AML/MDS were treated by AZA). The overall satisfaction rate was 95%.
Aims: Our work aimed to demonstrate that HaH administration of AZA is feasible and well preferred by patients compared to hospital administration.
Methods: Chemotherapy at home obeys to strict rules. The first chemotherapy cycle (C1) and the first injection (D1) of subsequent cycles were administered at the outpatient care unit. The following injections were administered at the patient's home and carried out by HaH, according to a predefined procedures (Fig 1) to comply with safety rules essential to the protection of the professional, the patient, the entourage and the environment. Subcutaneous AZA injections were administered at a dose of 75mg/m^2 for 7 days of each 28-day cycle. Between 2009 and 2015, 169 patients were treated with AZA by a combination care in outpatient unit and HaH and were included in the study. In February 2017, we set up a satisfaction survey with an anonymized questionnaire for all patients alive at the date of dispatch. The aim is to assess several criteria such as the degree of satisfaction, quality of care, well-being, personal anxiety, advantages and disadvantages. Each item will be analyzed using a Likert scale to realize a satisfaction survey.
Results: From 2009 to 2015, a total of 6369 subcutaneous injections of AZA were administered at home for 169 pts with AML/MDS received AZA therapy. Among all pts, 110 were males and 59 females with a median age of 75 years (range 41-92) there are 88 (52%) MDS patients and 81 pts (48%) with AML. Patients received a median number of 5 cycles (1-41) and 26 injections of AZA (1-244) at home. The total duration of HaH management lasted from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 out of 169 pts (60%) had to return to conventional hospital for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Figure 1.

Summary/Conclusions: This important number of subcutaneous injections (n=6369) in a large cohort (n=169) over a period of time of 6 years activity show that home administration of subcutaneous AZA is feasible without serious adverse event. The first satisfaction survey demonstrates a high rate of satisfaction by all patients (20% with AML/MDS) treated by injectable chemotherapy at home. The results of the satisfaction survey, focused on pts treated with subcutaneous AZA, is in process and results will be presented at the EHA meeting.

E1459

USE OF COMBINED ORAL FENTANYL CITRATE (ACTIQ®) AND MIDAZOLAM AS PREMEDICATION FOR BONE MARROW BIOPSY IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A RANDOMIZED CONTROLLED PATIENT BLINDED CLINICAL TRIAL

C. Cerchione[1,*], M. PIcardi[1], N. Pugliese[1], R. Della Pepa[1], A. Gravetti[1], A. Casoria[1], L. Catalano[1], D. Nappi[1], G. Ciancia[2], G. Pettinato[2], F. Pane[1], V. Martinelli[1]
[1]Hematology, Ematologia e trapianto/au federico ii, [2]Anatomia Patologica, AOU Federico II, Napoli, Italy

Background: Bone marrow aspiration and biopsy (BMAB) is a painful procedure, and the commonly adopted local infiltration anesthesia (LIA) with lidocaine is unable to relieve the pain during the most uncomfortable phases, or the anticipatory anxiety related to pain recalling thereafter. As there are no formal guidelines for adding a sedoanalgesic premedication before beginning the BMAB, many combinations have been adopted by several authors.
Aims: Our randomized and patient blinded trial aimed to evaluate, as primary end point, the efficacy and safety of opioid and benzodiazepine agent combination plus LIA in patients who underwent BMAB for hematological malignancies. Two secondary end points were: 1) define if patients who already underwent to BMAB without LIA prefer sedoanalgesia; 2) sedoanalgesia can influence the quality of the biological specimen harvested.
Methods: Patients were randomly assigned into two arms for receiving either sedoanalgesic placebo plus LIA (standard group, 48,6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51,4%) during BMAB. Pre-procedural anxiety and procedural pain were assessed according to the Numered Rating Scale (NRS: 0-10), dividing the time of the procedure into five intervals (T0, T1, T2a, T2b, and T3) and evaluating discomfort grade during each moment of procedure in both groups. Cognitive function was measured before and 30 minutes after the procedure. Possible side effects were recorded, as well as the adequacy of tissue samples harvested. A telephone interview was performed 24 hours later. A total number of one-hundred-sixteen (n=116, Table 1) were enrolled in the study. Nine (n=9) patients did not meet inclusion criteria and were excluded. Fifty-two (n=52) patients were randomized and assigned to standard group and fifty-five (n=55) to combo group.
Results: At T2b and T3 (corresponding to the biopsy time and time after the biopsy, respectively) there was a significantly lower ($p< 0.05$) perception of pain in the patients who received sedo-analgesia (combo-group) compared to those who did not (standard group). Moreover, 100% of the patients in combo group who had previously undergone this procedure without premedication, reported that they would prefer sedoanalgesia for the subsequent procedures, thus showing the effectiveness of this combination also in relieving anticipatory anxiety. Finally, the histological specimen was found to be high in quality, as defined by standards.

Table 1.

Table 1. Baseline characteristics of the population undergone to BMAB

Characteristic	No.
Number of patients	107
Sex	
Male/Female	9/5
Age, years	
Median (range)	61 (19-84)
Type of hematologic neoplasm	
Acute myeloid leukemia	19
Non Hodgkin lymphomas	16
Myelodisplastic syndromes	16
Multiple Myeloma	13
Essential thrombocythemia	11
Polycythemia vera	10
Chronic lymphatic leukemia	7
Hodgkin lymphoma	6
Primary myelofibrosis	5
Acute lymphoblastic leukemia	5
Chronic myeloid leukemia	4

Summary/Conclusions: Administration of oral analgesia and anxiolysis is a safe and feasible option to be used in outpatient setting; sedo-analgesia is very effective in reducing pain during the biopsy and diminishes the anticipatory anxiety related to a painful procedure. Patients should have the possibility to choose between local anesthesia alone or sedo-analgesia plus local anesthesia.

E1460

ASSESSMENT OF THE ECONOMIC IMPACT OF HORSE-ATG IN SWEDEN FOR APLASTIC ANAEMIA

R. Desmond[1], R. Peffault de Latour[2], A. Risitano[3], K. Sutton[4], E. Remak[5], M. Barra[5], V. Katkade[6,*], C. Charbonneau[7]
[1]Hematology, Tallaght Hospital, Dublin, Ireland, [2]Hematology, Saint Louis Hospital, Paris, France, [3]Hematology, Department of Clinical Medicine and Surgery, Federico II University of Naples, Naples, Italy, [4]Modeling & Simulation, Evidera, London, United Kingdom, [5]Modeling & Simulation, Evidera, Budapest, Hungary, [6]Pfizer, Philidelphia, United States, [7]Pfizer, Paris, France

Background: Aplastic anaemia (AA) is a rare, potentially fatal haematopoietic stem-cell disorder that can either be inherited or acquired. AA is graded according to disease severity, from non-severe to very severe and is linked to immune-related responses such as the destruction of the bone marrow. Cases of severe and very severe AA are considered to be a haematological emergency requiring urgent treatment. Extended hospitalisations and the cost of treatments and disease management are associated with the economic impact of AA.

Aims: To assess cost-effectiveness of ATGAM (horse antithymocyte globulin) in comparison to rabbit antithymocyte globulin (r-ATG) in the treatment of moderate to severe aplastic anaemia (sAA) patients in Sweden.
Methods: A semi-Markov state-transition cohort model was developed to estimate longer-term (up to five years) clinical and economic outcomes for patients with AA receiving either ATGAM or r-ATG as first-line IST treatment. The following key assumptions were included in the model: responders who relapse are assumed to be re-treated with no expected change in survival. Patients that do not respond to first-line treatment move onto a second-line treatment comprised of either IST, IST + eltrombopag or hematopoietic stem cell transplantation (HSCT). Although response rates are lower, those who respond to second-line treatment are assumed to have the same outcomes as those who respond to first-line. Patients who continue to not respond receive standard supportive care with a significant decrease in expected survival. Efficacy data for ATGAM and r-ATG were obtained from published literature. Adverse events were not included due to lack of evidence of any difference between the two comparators. Medication, administration, and disease management costs were obtained from published literature, publicly available sources and clinical expert opinion. As resource utilization for disease management changes over time and differs considerably between responders and non-responders, three distinct phases have been included in the model: short-term (first 6 months post-IST administration), medium-term (6-12 months) and long-term (greater 1 year), for patients in either of the response categories.
Results: Response to treatment was calculated to be seen in 67% of ATGAM patients' *vs* 35% in r-ATG (accounting for mortality). Over 5 years, the model estimated that patients gained 4.15 life-years (3.28 quality-adjusted) on ATGAM *vs* 3.52 (2.56) on r-ATG. Short-term disease management costs were estimated to be SEK 880,144 (€96,816) in responders *vs* SEK 1,264,016 (€139,041) in non-responders. Medium and long-term costs also followed the same pattern. Overall costs (drug plus disease management), were significantly lower for patients receiving ATGAM *vs* r-ATG; making ATGAM cost-saving by being both more effective and less costly than r-ATG. When considering treatment costs only (including cyclosporine and HSCT), the model estimated a cost of SEK 107,097/life-year gained (approx. €11,781) and SEK 135,655/quality-adjusted life-year (approx. €14,922), showing ATGAM is highly cost-effective. The analysis showed that when treatment and disease management costs are considered, ATGAM dominates r-ATG as the gain in QALYs and LYs are achieved at a lower cost. Therefore making ATGAM cost-saving with greater health benefits in comparison to r-ATG.
Summary/Conclusions: Due to improved treatment response, survival, and quality of life outcomes, the model shows that ATGAM is at least more cost-effective, if not cost-saving, in comparison to r-ATG for the treatment of patients with aplastic anaemia.

E1461

NEUROPSYCHOLOGICAL ANALYSIS OF LONG-TERM CONSEQUENCES OF ANTINEOPLASTIC TREATMENT

A. Nesterova [1], S. Khrushchev[2,*], D. Vybornykh[2], A. Tkhostov[3]
[1]Open Institute - Higher Professional School, [2]National Research Institute for Hematology, [3]Lomonosov Moscow State University, Moscow, Russian Federation

Background: Study of long-term consequences of conducted antineoplastic treatment is becoming on the front burner because of significant increase in survival rates of Acute Lymphoblastic Leukemia (ALL) and Hodgkin's Lymphoma (HL) patients. Modern therapeutic protocols (cranial irradiation and chemotherapy) can negatively affect patients' cognitive functions and consequently decrease patients quality of life. It is therefore necessary to carry out qualitive and quantative analysis of neuropsychological impairments in patients conducted antineoplastic treatment.
Aims: The aim of the research to study neuropsychological status (memory and executive funcions) of adult patients after antineoplastic therapy in childhood.
Methods: Patients in a present clinical remission (5-14 years remission duration). N=60 (ALL), N=50 (HL). Mean age-14 (ALL), (HL) – 19 years. N=60 control group. Qualitative, quantitative neuropsychological scales developed in Luria's approach methodology (tests for dynamic praxis and memory domains) and one-way ANOVA on ranks were used.
Results: The main neuropsychological impairments were found in auditory-verbal memory and auditory-motor coordination (memory narrowing, violations in selectivity, inertia in mental process, perseverations, contaminations, difficulties in praxis automatisation). 20% of patients didn't recall all words (auditory-verbal memory tests) after four representations (3,3% in control group, p<0,005). 19% of patients failed or had severe difficulties in dymanic praxis tests (2% in control group, p<0,005). The results point at possible deficits in temporal and frontal parts of the brain (predominantly posterior frontal and mediobasal systems).
Summary/Conclusions: Neuropsychological impairments in audioverbal, auditory motor and dynamic praxis spheres, qualitive and quantative analysis showed deficits in temporal and posterior frontal areas of the left hemisphere, that can be as a result of antineoplastic therapy in childhood. Such findings can improve understanding the nature of patients impairments and difficulties they experience. Rehabilitation programs should take into account patients neuropsychological changes and cognitive decline. Indeed psychological interventions are necessary in long-term period after clinical remission.

E1462

A CLINICAL AUDIT OF NUTRITIONAL SCREENING AND SUPPORT OF HOSPITALIZED PATIENTS WITH HEMATOLOGIC DISEASES

A. Stamou[1], A. Liaskas[1], I.-G. Tzanninis[1], E. Kanioura[1], D. Politis[1], L. Poulia[2], N.-A. Viniou[1], K. Konstantopoulos[3], P. Diamantopoulos[1,*]
[1]1st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, [2]Clinical Nutrition Department, Laikon General Hospital, [3]Hematology Department, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background: Poor food intake is a common problem in patients with hematologic diseases. Recurrent infections and chemotherapy complications are some of the possible causes. Malnutrition is correlated to slow recovery, prolonged hospitalization, and higher mortality. Audits about the nutritional support of hospitalized patients may detect significant failures in patient care and help towards the correct application of the international guidelines.
Aims: We performed a prospective observational audit on hospitalized patients with hematologic diseases to investigate their nutritional status and whether they received the appropriate nutritional support.
Methods: The initial population consisted of 122 consecutive patients with hematologic diseases admitted from March 31, 2016 to June 8, 2016 in two Hematologic Units of a Tertiary University Hospital in Athens, Greece. We designed a special questionnaire based on the Malnutrition Universal Screening Tool (MUST) with additional questions on demographic, somatometric and medical data (Table 1). The questionnaire was applied by 6th-year medical students to all patients within 48 hours of admission. Patients were classified as high, intermediate, and low-risk per the MUST score and were reassessed at predefined intervals. During reassessment, we examined the food intake and the nutritional interventions (nutritional supplements, enteral or parenteral nutrition) applied.
Results: Ninety-three patients were included in the final analysis (5 refused to participate, 22 were excluded due to short-term hospitalization, 2 were absent during reassessment). Forty-one (38%) patients had a MUST score ≥2 (high risk) but none of them received nutritional supplements. One patient was supported with parenteral nutrition (Table 1).

Table 1.

Table 1: Patients' characteristics and results

Number of patients, N (%)	93 (100)
Age (years), median (range)	57.5 (17-87)
Gender (M/F)	1.4
BMI (kg/m^2), median (range)	25.39 (16.95 – 40.64)
% of unplanned weight loss in past 6 months, median (range)	3.6 (0-25.3)
Disease, N (%)	
Lymphoproliferative disorders/ Multiple myeloma	45 (49)
Acute leukemia/ Myeloproliferative disorders	38 (41)
Benign hematologic disorders	5 (5)
No confirmed diagnosis	5 (5)
MUST, N (%)	
0	41 (44)
1	14 (15)
≥2	38 (41)
Patients receiving nutritional support, N (%)	1 (1) *
Recent chemotherapy/radiotherapy, N (%)	45 (48)/ 3 (3)
Reported food intake (last 5 days), N (%)	
Increased	1 (1)
Normal	61 (66)
Decreased	29 (31)
No intake	2 (2)
Serum albumin levels on admission/at discharge (g/dl), median(range)	4.1 (2-4.9)/ 3.6 (2.3-4.5)
Other variables: estimated food intake in 5 days, reduced appetite, type of diet, calorie intake, duration of hospitalization, ECOG score, recent surgery, dysphagia, nausea, mucositis, infection, neurological deficits, head trauma etc.	
*a 65-year-old woman with 12% weight loss over the last month, BMI=21 kg/m^2, albumin=2 g/dl, a hospital-acquired infection and no food intake.	

Summary/Conclusions: Our audit revealed a lack of nutritional support of the hospitalized patients. A meeting with the involved health professionals was organized and an oral presentation of the results and the possible causes (lack of sensitization of the staff, high regimen cost, shortness of staff) was performed. Proposals to change the current situation were made such as detection of high risk patients by medical students and further assessment by a nutritional specialist. A brief MUST-based questionnaire was also proposed to be used for all patients upon admission. A re-audit was programmed and is already in progress.

E1463

ASSESSING REAL-WORLD TREATMENT PATTERNS, OUTCOMES AND RESOURCE USE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) POST AUTOLOGOUS STEM CELL TRANSPLANT ACROSS EUROPE

J. Ashcroft[1], G. Taylor-Stokes[2], S. Dhanasiri[3], D. Judge[2,*]
[1]Mid-Yorkshire Hospitals NHS, Wakefield, [2]Adelphi Real World, Bollington, United Kingdom, [3]Celgene International, Boudry, Switzerland

Background: Autologous stem cell transplant (ASCT) is the standard of care for first line (1L) treatment (tx) for patients (pts) with MM deemed of suitable fitness to safely undergo the procedure. More recently introduced tx options have significantly increased the life expectancy of pts with MM and continue to provide further promise for the future in this devastating disease. The increasing therapeutic armoury across the MM pathway allows for varied tx patterns providing both potential differences in outcomes and healthcare resource use (HCRU).
Aims: The aim of the analysis was to determine current management of pts in the post ASCT setting, assess outcomes of pts and HCRU.
Methods: A retrospective chart review was conducted in France, Germany, Italy, Spain and the UK. Data collection took place in Q1 2017. Physicians provided data on consecutive pts with MM who had undergone an ASCT as part of 1L tx on or after 1st January 2014, to specifically examine the HCRU post 1L SCT. Data collected pertained to pt characteristics, tx patterns, duration of tx and outcomes (including time to progression (TTP) and best response achieved (IMWG updated criteria), HCRU in terms of hospitalizations, additional supportive drugs prescribed and healthcare professional (HCP) visits. Pt records included in this interim analysis were completed by Feb 17th 2017, with data collection continuing in all countries.
Results: 214 record forms have been reviewed to date. Pts' mean age at diagnosis was 59 (±7.8 SD) years; 43% female and 57% male. Mean duration from diagnosis, to receiving an ASCT was 9.6 months (±13.3 SD). Of the pts included in the study, 62%, 28% and 8% had received 1st, 2nd and 3rd line tx respectively. In the 1L setting, 72% of pts did not receive any drug therapy post ASCT, 21% received consolidation and 8% maintenance therapy. Of the pts who did not receive maintenance therapy, 42% and 34% went onto receive 2L and 3L drug therapy respectively; whereas, only 24% of pts who received maintenance therapy went onto 2L, and none onto 3L. The most frequently prescribed regimens at 1L maintenance were Lenalidomide (82%), Bortezomib (12%) and Thalidomide (1%). The mean TTP from start of 1L tx was 22.2 months (±11.1 SD) for pts not receiving maintenance and 33.0 months (±8.1 SD) for pts receiving maintenance. Overall 43% of pts achieved a sCR and CR, 51% achieved a VGPR and PR. During the period from 1L post ASCT to start of 2L, 54% of pts required supportive tx (bisphosphonate (55%), blood transfusions (24%), G-CSF (21%), ESAs (11%), radiotherapy (4%) and dialysis (3%)). 64% of pts were hospitalized at least once during this period, with a mean duration of 7.2 days (±18.1 SD). The mean number of visits to Hematologists was 7.1 times in 24.8 months (between start of 1L to start of 2L tx); mean visits to a HCP during this period were 17. The mean TTP from start of 2L tx was 11.2 months (±6.8 SD). 20% of pts achieved a sCR and CR, 52% achieved a VGPR and PR.
Summary/Conclusions: The sample is reflective of the pt demographics data reported in Raab *et al.* 2016. Furthermore, the TTP for pts not receiving any active ongoing tx post ASCT in this real-world study is comparable to findings in other studies. Limited or no data exists on HCRU post ASCT. This study demonstrates that there is ongoing HCRU impact even if pts are not receiving any active ongoing tx post first ASCT. Prolonging the remission period post ASCT may therefore spread the marginal cost of HCRU whilst simultaneously enhancing a pt's quality of life by deferring future tx lines.

E1464

NUMBER-NEEDED-TO-TREAT (NNT) AND COST OF RESPONSES ACHIEVED IN TYROSINE KINASE INHIBITOR (TKI) TREATMENT OF REFRACTORY CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) IN THE UNITED STATES (US)

M.Y. Levy[1,*], L. McGarry[2], S. Iannazzo[3], H. Huang[2], S. Chiroli[4]
[1]Baylor University Medical Center, Dallas, TX, [2]ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States, [3]SIHS Health Economics Consulting, Torino, Italy, [4]INCYTE, Epalinges, Switzerland

Background: The emergence of targeted therapies with high efficacy in small patient populations such as TKI-refractory CP-CML has challenged decision-makers.
Aims: To demonstrate a simple and intuitive approach to assessing the value of available TKIs (nilotinib, dasatinib, ponatinib and bosutinib) in this setting.
Methods: Using synthesized efficacy data from a published meta-analysis (Lipton 2014), we calculated NNT to achieve one additional response, defined as complete cytogenetic response (CCyR), for CP-CML patients treated with a TKI after failing ≥2 prior TKIs. NNT represents the expected number of treated patients required to achieve one additional response—*i.e.*, the multiple of treated patients to responders. We assumed response is not evaluated prior to 3 months, per National Comprehensive Cancer Network (NCCN) guidelines. Therefore, the cost of achieving an additional response was estimated as the product of NNT and 3-month cost, based on US Wholesale Acquisition Costs (WAC) and recommended dosing for each TKI from US prescribing information (USPI).
Results: To achieve one expected response, the NNT is 1.7 (95%CrI: 1.5-1.9) patients for ponatinib, 3.8 (3.1-4.8) for nilotinib, 4.2 (2.2-11.1) for dasatinib, and 4.5 (3.4-6.7) for bosutinib (based on CCyR of 60%, 26%, 24% and 22%, respectively). With a 3-month WAC for ponatinib of $49,683, nilotinib: $33,892, dasatinib: $33,897 and bosutinib: $36,045, the estimated 3-month cost per response achieved is $82,800 ($73,100-$95,500) for ponatinib, $130,000 ($106,000-$161,000) for nilotinib, $141,000 ($75,300-$377,000) for dasatinib, and $164,000 ($124,000-$240,000) for bosutinib.
Summary/Conclusions: Using published, synthesized efficacy estimates, the NNT to achieve response with ponatinib in TKI-refractory CP-CML is less than with nilotinib, dasatinib or bosutinib. Despite a higher WAC, ponatinib has the lowest estimated 3-month cost per response achieved. Therapy choice should, however, consider both treatment cost and the benefit-risk profile of the individual patient.

E1465

THE COST-EFFECTIVENESS OF PEGASPARGASE FOR FIRST-LINE TREATMENT OF ACUTE LYMPHOBLASTIC LEUKAEMIA: A COST-UTILITY ANALYSIS

S. Basu[1], P.L. Lin[2], C. Rowntree[3,*], V. Saha[4]
[1]Shire, London, United Kingdom, [2]Shire, Cambridge, United States, [3]University Hospital of Wales, Cardiff, [4]University of Manchester, Manchester, United Kingdom

Background: Asparaginase is a key component in the multi-agent chemotherapeutic regimen for the treatment of children, adolescents, and adults with acute lymphoblastic leukaemia (ALL). Compared to native asparaginase (native ASP), pegaspargase (PEG-ASP) has a longer half-life, can be given less frequently, and is less immunogenic, which leads to fewer hypersensitivity reactions. In the UK, patients with newly diagnosed ALL are treated with PEG-ASP followed by Erwinia-derived asparaginase (ERW-ASP) in cases of hypersensitivity, based on the UKALL protocols. Although native ASP is no longer used as the first choice of asparaginase therapy, it was the standard of care before PEG-ASP was available. A cost-utility analysis (CUA) was conducted to evaluate overall cost-effectiveness of PEG-ASP in comparison to native ASP when utilized as part of antineoplastic combination therapy for treating newly diagnosed ALL in children, young people, and adults.
Aims: To evaluate the cost-effectiveness of a treatment strategy including PEG-ASP in a multi-agent in patients with newly diagnosed ALL compared to regimens that include native ASP.

Table 1.

Technologies	Total		Incremental		ICER (£)
	Cost (£)	QALYs	Cost (£)	QALYs	
PEG-ASP > ERW-ASP	£7,871	17.3431	—	—	—
Native ASP > ERW-ASP	£12,612	17.2926	–£4,741	0.0504	Dominated*
ERW-ASP > Native ASP	£48,149	17.3396	–£40,277	0.0035	Dominated*
ERW-ASP > PEG-ASP	£48,234	17.3477	–£40,362	–0.0047	£8,627,243

* Dominated indicates more costly and less efficacious compared to the PEG-ASP > ERW-ASP sequence.

Methods: In line with accepted National Institute for Clinical Excellence (NICE) methodology, a combined decision tree and health state transition Markov model was developed to compare treatment sequences starting with PEG-ASP *versus* native ASP, followed by ERW-ASP in case of hypersensitivity. Although ERW-ASP is not used first-line in the United Kingdom, alternative switching scenarios could be clinically possible, and therefore all scenarios were modelled. Paediatric, young adult (≤25 years), and adult (26-65 years) patients were modelled separately using the UKALL 2003 and UKALL14 protocols, respectively. Further splits were made between high-, intermediate-, and standard-risk patients in the paediatric model, between patients aged ≤40 *vs* ≥41 years, and patients eligible *versus* not eligible for transplant in the adult model. Key model parameters (survival, risk of hypersensitivity) were based on published data and clinical expert input. In the base-case analysis, overall survival and event-free survival were assumed to be equivalent for PEG-ASP, native ASP, and ERW-ASP, with 1,000IU/m^2 dosing (per UKALL protocols) used for PEG-ASP. In the scenario analyses, the 2,500 IU/m^2 dosing (per SmPC) of PEG-ASP was examined, as well as variations in comparative survival and hypersensitivity rates. Incremental cost-effectiveness ratios (ICER; defined as incremental costs/quality-adjusted life years [QALYs] gained) were produced.

Results: The base-case scenario demonstrated that PEG-ASP followed by ERW-ASP dominated (*i.e.*, was both less costly and more effective than) native ASP followed by ERW-ASP in adults, children, and the whole (combined) population (Table). Scenario analyses highlighted the robustness of the cost-effectiveness results. Differences in total QALYs between PEG-ASP and native ASP were driven primarily by the difference in hypersensitivity rates.
Summary/Conclusions: This analysis demonstrates that PEG-ASP, as part of multi-drug chemotherapy, is a cost-effective treatment option compared to native ASP for treating ALL in children, young people and adults with newly diagnosed ALL.

E1466

IMPACT OF VENETOCLAX ON THE QUALITY OF LIFE OF PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS OF A PHASE 2, OPEN-LABEL STUDY OF VENETOCLAX (ABT-199/GDC-0199) MONOTHERAPY

W. Wierda[1,*], K. Sail[2], L. Noe[2], R. Kamalakar[2], J. Gdovin[2], M. Verdugo[2], S. Kim[2], R. Humerickhouse[2], S. Stilgenbauer[3]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]AbbVie Inc, North Chicago, United States, [3]Department of Internal Medicine III, Ulm University, ULM, Germany

Background: Chronic lymphocytic leukemia (CLL) is associated with reduced health-related quality of life (HRQoL), with progressive severe fatigue being a particularly relevant burden. Disease-related symptoms, toxic effects of therapy, and the awareness of living with an incurable disease can have a profound impact on HRQoL. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.
Aims: To assess whether Venetoclax has a sustained impact on health related quality of life among patients with relapsed/refractory CLL based on a second interim analysis (first interim results through week 24) of patients treated with VEN monotherapy.
Methods: Patients ≥18 years of age with R/R CLL received VEN monotherapy until disease progression, unacceptable side effects, or discontinuation for any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), at 4 weeks and every 12 weeks thereafter. Mean change in the HRQoL measures from BL to each assessment are reported. Clinical relevance was based on minimum important difference (MID) of values from BL at different assessment points. The lower bound of 5–10 point changes, considered a "little" change for EORTC-QLQ-C30 was used for MID acceptance for both measures.
Results: Clinically meaningful improvements from BL were observed early and were sustained through week 96 in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Improvements in VEN treated patients in EORTC-QLQ-CLL16 disease effects, social problems, and future health worries scores were statistically significant and exceeded the MID at all assessment points. Furthermore, early and sustained improvements in fatigue through week 96 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1). The changes observed in patient EORTC-QLQ-CLL16 future health views were considered large (>20 points) at Weeks 12, 24, and 48.

Table 1.

Table 1. Change from Baseline Results in Key Domains on EORTC QLQ-C30 and EORTC QLQ-CLL16

EORTC QLQ-C30 parameter (n)	BL Mean	Visit Mean	Mean Change from BL (95% CI)
Global Health Status*			
Week 12 (111)	60.4	68.5	8.1 (3.6, 12.6)
Week 48 (92)	62.5	73.2	10.7 (6.3, 15.0)
Week 96 (50)	58.2	68.8	10.7 (4.7, 16.7)
Fatigue†			
Week 12 (118)	35.8	27.4	-8.3 (-12.5, -4.2)
Week 48 (99)	33.3	25.3	-8.0 (-12.7, -3.3)
Week 96 (52)	35.3	26.5	-8.8 (-16.0, -1.5)
EORTC QLQ-CLL16 parameter (n)	**BL Mean**	**Visit Mean**	**Mean Change from BL (95% CI)**
Fatigue†			
Week 12 (117)	29.6	19.2	-10.4 (-15.1, -5.7)
Week 48 (97)	29.0	20.1	-8.9 (-14.2, -3.6)
Week 96 (53)	30.5	21.4	-9.1 (-16.8, -1.4)

* A positive change in score represents improvement.
† A negative change in score represents improvement.

Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.

E1467

WHICH HAEMATOLOGICAL CONDITIONS CAN THIRD YEAR MEDICAL STUDENTS RECOGNISE INTERPRETING FULL BLOOD COUNT RESULTS?

S. Lovato[1,2,*], J. Arnold[1,2]
[1]Postgraduate, London North West Healthcare NHS Trust, [2]Undergraduate, Imperial College London, London, United Kingdom

Background: Haematology is often seen by medical students as a niche specialty, however interpreting full blood count results is a daily job for most hospital doctors. Furthermore a recent review showed that survival for haematological malignancies is worse in UK than in other European countries, late diagnosis being one the possible causes. Educate future doctors in interpreting symptoms and blood results correctly to suspect haematological condition should be considered essential. In the UK the Education Subcommittee of British Society for Haematology wrote the "A Haematology Curriculum for Medical Students" as a guide to the knowledge of haematology expected from medical students.
Aims: The aim of the study was to evaluate the ability of a group of third year medical students in recognising ten haematological conditions as indicated in the curriculum proposed by the BSH. The students had all attended a haematology course during their second year of medical school.
Methods: A multiple choice test "best of four" containing ten clinical cases including full blood count results was given to the students. According to the Team Based Learning "TBL" model the students completed the test first individually, "i-RAT" and then after discussing the results in small groups "t-RAT". The topics and the percentage of correct answers are shown in table 1.
Results: Twenty four students participated. In the i-RAT none of the scenarios were correctly interpreted by 100% of the students, the scenarios interpreted correctly by at least 70% of the students were only two: B12/folate deficiency and iron deficiency; less than 30% of the students could identify CML, NHL and Multiple myeloma; the remaining topics: thalassemic trait, MDS AML, CLL and lymphocytosis due to viral infection were correctly diagnosed by a variable number of students, between 66% and 42%. When the test was repeated after discussion in small groups "t-RAT" there was an improvement of the percentage of correct answer with the exception of the topic AML. In the t-RAT 100% of the groups diagnosed correctly thalassemic trait and MDS, at least 70% of the groups identified correctly CML, CLL and multiple myeloma in addition to B12/folate and iron deficiency, there was an improvement in diagnosis of Multiple myeloma, but still less than 30% of the groups could identify NHL.

Table 1.

Table 1: topics and percentage of correct answers

TOPICS	% OF CORRECT ANSWERS	
	i-RAT	t-RAT
B12/folate deficiency	83	86
Iron deficiency	71	86
Thalassemic trait	66	100
MDS	66	100
AML	58	43
CLL	46	86
Lymphocytosis due to viral infection	42	43
CML	21	71
NHL	21	29
Multiple myeloma	17	57

Summary/Conclusions: This group of medical students found it difficult to correctly diagnose some of the haematological conditions presented, even though they had studied all the conditions before, however the use of a "Team Based Learning" approach where students could discuss the cases in small groups did improve their results. Interestingly for two conditions, for CML and Multiple myeloma the number of correct answers was the same for i-RAT and t-RAT, possibly the students who responded correctly during the i-RAT were each in a different group during the t-RAT and worked as peer-to-peer teachers for the other students. The t-RAT results for AML were actually worse than for the i-RAT, probably the students who replied correctly in the i-RAT were concentrated in fewer groups. To the author's knowledge this is the first study on the effect of applying the Team Based Learning method to haematology teaching. This study showed that TBL could be a useful teaching tool to improve teaching of haematological conditions in medical schools, however the size of the sample was small and the results should be validated with a bigger study.

E1468

LONGITUDINAL ASSOCIATIONS BETWEEN HEALTH-RELATED QUALITY OF LIFE AND HEALTHCARE UTILIZATION IN AL AMYLOIDOSIS

M. Bayliss[1], T.P. Quock[2], S.D. Guthrie[2], M.K. White[1], K.L. McCausland[1,*]
[1]Optum, Lincoln, [2]Prothena Biosciences Inc, South San Francisco, United States

Background: Light chain (AL) amyloidosis is a rare, complex disease associated with significant organ dysfunction, disability, and death. AL amyloidosis patients interact with the healthcare system in a myriad of ways; however, few studies have quantified healthcare utilization (HCU) in this condition.
Aims: To prospectively examine the association between health-related quality of life and healthcare utilization among patients with AL amyloidosis.

Methods: A non-interventional, longitudinal online study was conducted among patients with AL amyloidosis who were recruited with assistance from patient advocacy groups. Initial (n=341) and six-month follow-up (n=226) surveys assessed demographics, disease and treatment characteristics, and health-related quality of life (HRQoL), measured by the SF-36v2® Health Survey physical and mental component summary scores (PCS and MCS). HCU (e.g., outpatient doctors' visits, emergency room [ER] visits, hospitalizations, and insurance coverage) was measured during the six-month follow-up. Prevalence of HCU and its bivariate associations with patient characteristics were evaluated. Multivariable logistic regression models were used to test for associations between HRQoL and having an ER visit or hospitalization in the past six months.
Results: Overall, visits with specialists and other healthcare providers during the previous six months were nearly ubiquitous (92.0% and 94.6%, respectively). Collectively, 56.0% of patients reported having ≥1 ER visit or hospitalization. ER visits and hospitalizations were not associated with the numbers or types of organs affected by the disease or the duration of disease. There were significant associations between PCS and ER visits ($p<0.05$) and between both PCS and MCS and hospitalizations ($p<0.05$ for all) based on multivariable analyses.
Summary/Conclusions: There is a lack of real-world evidence regarding HCU among patients with AL amyloidosis. This research identified longitudinal associations between HRQoL and HCU, indicating there is potential for using HRQoL surveys as screening tools to predict future HCU for AL amyloidosis patients. The development of prediction models for HCU in AL amyloidosis should consider incorporating HRQoL, as well as disease staging and treatment type.

E1469

SAFETY, FEASIBILITY AND EFFECTIVENESS OF ELECTRICAL MUSCLE STIMULATION IN HOSPITALIZED PATIENTS UNDERGOING AUTOLOGOUS OR ALLOGENEIC STEM CELL TRANSPLANTATION AND INTENSIVE CHEMOTHERAPY

D. Kaddu-Mulindwa[1], A. Klostermann[1,*], M. Bewarder[1], J. Bittenbring[1], M. Pfreundschuh[1]
[1]Innere Medizin I, Universitätsklinikum des Saarlandes, Homburg, Germany

Background: Autologous and allogeneic stem cell transplantation (HSCT) or intensive chemotherapy are the only treatment option for many patients with haematological malignancies. Even after complete remission many patients are physically and psychologically impaired because of intensive treatment and weeks of immobilisation. Electrical muscle stimulation (EMS) is a verified training tool to prevent muscle decline in seniors and helps improving physical performance in patients with chronic disease.
Aims: This prospective, randomized and controlled study tested the safety, feasibility and efficacy of EMS in 72 patients (EMS=42, control=30) undergoing autologous HSCT (n=21), allogeneic HSCT (n=17) and intensive chemotherapy (n=34).
Methods: A Myopuls 2000 device (Curatec Services GmbH) was used. Targeted training time was 15 minutes 5 days a week on both thighs and arms from start of therapy (T1) to time of discharge (T2). Adverse events and treatment adherence were documented. Impact on psychological and physical functioning was evaluated using the Multidimensional Fatigue Inventory (MFI), the EORTC QLQ-C30, the Short Physical Performance Battery and the 6 Minute Walking Distance test at T1 and T2.
Results: Seven patients died in the EMS- (n=4) and control-group (n=3). 6 of 42 EMS patients withdrew because of sepsis (n=4) or loss of motivation (n=2). 32 patients from the EMS group completed our study with 22 accomplishing>66% of the pre-set training time. EMS related adverse events were hematoma (n=1) and muscle pain (n=2). No bleeding events (WHO bleeding scale>1) or ventricular arrhythmias occurred. Difference in 6-minute walking distance between both groups was 23 meter (p=0,2). SPPB test results differed by one point (p=0,08). MFI and EORTC QLQ-C30 both favoured the EMS group, but showed no statistical significance.
Summary/Conclusions: EMS is feasible and safe in patients undergoing intensive chemotherapy regimens. It also may improve physical fitness, fatigue and quality of life, indicated by favourable test results in the EMS group. To verify positive effects of EMS in patients with haematological malignancies, further research is needed, with more patients and sham EMS stimulation.

E1470

MYELOMA PATIENT VALUE MAPPING: A DISCRETE CHOICE EXPERIMENT

J. Galinsky[1,*], S. Fifer[2], S. Richard[1]
[1]Research, Myeloma UK, Edinburgh, United Kingdom, [2]Research, Community and Patient Preference Research, Sydney, Australia

Background: Myeloma is a life threatening haematological cancer. Although myeloma is responsive to treatments, there remains no cure. In recent years, there have been improvements in survival due to the use of high dose therapies, stem cell transplant, and other novel therapies. However, while myeloma patients are living longer, they are also living with symptoms and treatment side-effects. Therefore, myeloma patients face difficult decisions about the benefits and risks of treatment. The purpose of this study was to assess myeloma patient preferences for treatment.
Aims: The study aimed to answer the following questions: What treatment attributes do myeloma patients value? What is the relative importance of different treatment attributes to myeloma patients and the maximum acceptable risk they are willing to accept? What risk-benefit trade-offs characterise patients' decision-making around treatment options, including not to treat? What, if any, influences and predictive factors are found in the way patients assess benefits and risk?
Methods: Participants were 475 Myeloma patients in the UK. Data were collected using discrete choice experiments (DCEs) through an online survey. The DCEs presented patients with a traditional treatment choice experiment (*e.g.,* treatment A *vs* treatment B), focusing on the clinical benefits of treatments and the associated risks. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.
Results: Findings revealed two classes (groups) of patients with different preferences for treatment attributes. Patients in class one placed greater importance on overall survival and mild-to-moderate side effects, whereas patients in class two placed greater importance on how the treatment was administered and the average out-of-pocket costs. Patients living with others and those diagnosed in the last five years were more likely to be to be in class one (those more concerned with overall survival) than class two (those more concerned with quality of life).
Summary/Conclusions: Findings from this study suggest that not all myeloma patients value the same treatment features equally. This finding has important implications for healthcare policy decisions and could be used to guide decisions around the value of new myeloma medicines. For example, to establish more patient-aligned endpoints in clinical trials or as evidence which is incorporated into the Heath Technology Assessment process.

E1471

COST-MINIMIZATION ANALYSIS OF RITUXIMAB SUBCUTANEOUS FORMULATION *VERSUS* INTRAVENOUS ADMINISTRATION OF RITUXIMAB FOR THE TREATMENT OF NON-HODGKIN'S LYMPHOMA IN THE REPUBLIC OF MACEDONIA

O. Nikolov[1,*], Z. Sterjev[2], A. Dimovski[2], A. Kapedanovska-Nestorovska[2], Z. Naumovska[2], A. Grozdanova[2], L. Cevreska[3], B. Georgievski[4], A. Stojanovik[5], O. Karanfilski[6], S. Genadieva-Stavrik[4], S. Trajkova[6], A. Pivkova-Veljanovska[4], T. Sotirova[6], M. Pavkovic[5], S. Trpkovska-Terzieva[6], G. Amzai[6], L. Cadievski[4], D. Dukovski[6], L. Suturkova[2]
[1]Roche Macedonia DOOEL Skopje, [2]ISPOR - Republic of Macedonia Regional Chapter, Faculty of Pharmacy, Ss. Cyril and Methodius" University of Skopje, [3]University Clinic of Hematology, [4]Stem cell transplantation unit, [5]Outpatient Clinic, [6]Clinical department, University Clinic of Hematology, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Rituximab, an anti-CD20 monoclonal antibody, in combination with chemotherapy is a standard of care for non-Hodgkin's lymphoma (NHL), in a standard dose of 375mg/m^2 body surface area (BSA), administered by intravenous (IV) infusion, or fixed dose of 1400mg administered as subcutaneous formulation (rituximab SC). Intravenous infusion of rituximab typically last for three to four hours, while subcutaneous application last approximately five to seven minutes. The evidence to support the use of rituximab SC as an alternative to rituximab IV is primarily based on the phase III, randomised, non-inferiority, open-label SABRINA study. Recent studies demonstrated therapeutic and pharmacokinetic non-inferiority of rituximab SC to rituximab IV.
Aims: The aim of the study was to identify and compare the total costs of subcutaneous (SC) *vs* intravenous (IV) administration of rituximab for the treatment of NHL patients in the Republic of Macedonia.
Methods: Cost-minimization analysis was used to evaluate pharmacoeconomic impact of the use of subcutaneous *vs* intravenous administration of rituximab in the treatment of NHL patients. The total of 220 NHL patients (mean body surface area 1.9 m^2, middle aged 59.6 years) were enrolled in the study. Evaluated healthcare resources included drug treatment costs, infusion chair occupying cost, active Healthcare Professional time cost and consumable disposals.
Results: Direct costs of administering one course of rituximab, including cost of drug, cost of administration and cost of consumables in all treatment phases (premedication, medication and post medication), for intravenous administration of rituximab were 1621€ compared to 1546€ for subcutaneous administration of rituximab. Average time for intravenous administration is 6 hours, 12 minutes and 13 seconds, compared to 10 minutes and 13 seconds for subcutaneous administration. Subcutaneous rituximab incurred less non-drug related costs than intravenous rituximab under the observed clinical practice: 14.62€ *vs* 1.76€ regarding active healthcare professional time and 10.10€ *vs* 1.2€ as infusion chair occupying cost.
Summary/Conclusions: Subcutaneous administration of rituximab is a cost-saving therapy in comparison with intravenous administration of rituximab for the treatment of NHL patients in the Republic of Macedonia.

E1472

QUALITY OF LIFE AND ABILITY TO WORK OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA TREATED WITH THYROSINE KINASE INHIBITORS

B. Sidi Mohamed El Amine[1,*], H. Asma[1], Z. Zahia[1], M. Naima[2], M. Nemra[3]
[1]Hematology department, Universitary hospital of Sidi Bel Abbes, Sidi Bel Abbes, [2]Hematology department, Universitary hospital of Tlemcen, Tlemcen, [3]Hematology department, Hospital of Mascara, Mascara, Algeria

Background: Thyrosine kinase inhibitors (TKIs) are now standard treatment for chronic myelogenous leukemia (CML), but little is known about quality of life (QoL) of the patients.
Aims: The purpose of this study is to evaluate QoL of CML patients receiving TKIs, a disease requiring strict daily compliance with taking these drugs orally, as well as regular clinical and biological controls.
Methods: The study included patients with CML followed in three hospitals in west Algeria between 2004 and 2016. The measure of QoL was performed by the tool of functional assessment of chronic illness therapy (Functional Assessment of Chronic Illness Therapy, FACIT) for leukemia. We have established QoL scores given by the questionnaire, FACIT, consisting of three levels: TOI for leukemia trial outcome index, FACT-G for general score, and FACT-LEU for the total score of leukemia. Specific areas of the questionnaire were associated with QoL of patients such as fatigue and ability to work. The correlation between these data and QoL scores was assessed using Spearman's test. The test is significant if $p<0.05$.
Results: 67 patients with CML have agreed to answer to the questionnaire of QoL, medications in use, and their side effects. The mean QoL of the patients was 93.7 (out of 124 total points) for the TOI, 77,2 (out of 108) for the FACT-G, and 128.9 (out of 176) for the FACT-LEU. Patients who presented with TKIs side effects had a low score of QoL ($p=0.0006$), especially when these effects are severe ($p=0.003$). Stopping TKIs medication was noted in 41.3% of patients with severe side effects. Severe fatigue was observed in 14 (22.9%) patients, having low QoL scores in all scales ($p<0.0001$). 44 (65.8%) patients were able to work with higher QoL scores in the three FACIT scales ($p<0.0001$, Spearman correlation).
Summary/Conclusions: QoL is an important aspect in the management of CML, its assessment is necessary and must be regular. The ability to work and fatigue are important components of QoL of patients receiving TKIs and should be specifically taken into account during the treatment. Adverse effects of TKIs can interfere with QoL of patients and can lead to discontinuation of CML therapy.

E1473

QUALITY OF LIFE AND EMPLOYMENT AFTER AN HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A MEXICAN POPULATION

L. Rivera-Fong [1], A. Riveros Rosas[1], C. Benjet[1], L.M. Valero Saldaña[2], R. Robles García[1], L. Traeger[3], S. Rivas-Vera[2,*], J.L. Aguilar Ponce[4], O. Galindo Vázquez[5], B.L. Acosta Maldonado[2]
[1]Psicología y Salud, Universidad Nacional Autónoma de México., [2]Hematology, National Cancer Institute, Mexico, Mexico City, Mexico, [3]Health psychology, Hardvard University, Massachusetts, United States, [4]Oncology, National Cancer Institute, Mexico, [5]Psicología, Universidad Nacional Autónoma de México., Mexico City, Mexico

Background: Hematopoietic stem cell transplantation (HSCT) is a consolidation therapy for multiple hematological malignances and its goal include patients achieve levels of quality of life (QOL) similar that general population. However, studies developed in Europe and United States have shown that patients on long-term follow-up after HSCT reported lower levels of QOL, more unemployment and lower household income than before the procedure. These relationships have not been examined in Mexican HSCT patients.

Table 1.

Table 1. Levels of quality of life reported.

				17.9 (4.3)	19.32 (3.32)

Aims: To describe the QOL (EORTC-QLQ), level of employment and household income in Mexican patients on follow-up after HSCT
Methods: This was a cross-sectional study with patients ≥18 years old with at least one year of follow up after HSCT at the National Cancer Institute, Mexico.
Results: 30 participants were included, with a median age of 34 years (range 21-65), 56% male, and 41% married. Regarding educational level 68.7% had basic education, 25% had a college education and 6.3% postgraduate education. Mean time after HSCT was 36 months, 10% had active chronic graft *versus* host disease (GVHD). Patients reported moderate to high levels of QOL (Table 1). With respect to employment, 52% had a job (56% had a full time job, 13% work part-time and 31% had an informal job) and 48% were unemployed (50% could not find a job and 50% did not want to have a job). Finally, 56% had lower household income than before HSCT.
Summary/Conclusions: Mexican patients showed similar or higher levels of QOL in comparison with samples from other countries, with the exception of higher impact in emotional QOL and better social QL in our sample. Additionally, a substantial minority of patients were unemployed and over half had lower household income after HCST. More work is needed to identify risks associated with changes in QOL, employment status and income among long-term survivors of HCST.

E1474

ANTHRACYCLINE INCREASES THE RISK OF DEVELOPING DIABETES IN B CELL LYMPHOMA

H.-C. Lin[1,*], W.-L. Hwang[1], C.-L. Teng[1]
[1]Division of Hematology/Medical Oncology, VTaichung Veterans General Hospital, Taichung, Taiwan, Republic of China

Background: Treatments of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone) or R-CHOP like regimens have made B cell lymphoma to be one of the most curative hematological malignancies. Among the effective chemotherapeutic agents in B cell lymphoma treatment, anthracycline plays an important role. However, anthracycline associated bone marrow suppression and cardiotoxicity limit its clinical application. Whether anthracycline would further increase the risk of developing diabetes in B cell lymphoma remains unclear.
Aims: The aim of this study was to compare the cumulative incidences of diabetes in B cell lymphoma patients treated with and without anthracycline. We also investigated the dose effect of anthracycline on diabetes development. Additionally, whether anthracycline would increase the severity and complication of diabetes in B cell lymphoma patients were also studied.
Methods: We conducted this population-based study by using Taiwanese National Health Insurance Research Database. From 2004 to 2011, medical records from a total of 3984 B cell patients were analyzed. To understand whether anthracycline therapy was associated with more diabetes in B cell lymphoma, we compared the cumulative incidence of newly diagnosed diabetes between patients with (n=3147) and without (n=837) anthracycline treatments. Impact of anthracycline on diabetes was further studied by multivariate Cox proportional hazard regressions in a dose-dependent manner.
Results: Log-rank test did not show the difference of cumulative incidences of newly diagnosed diabetes between B cell lymphoma patients with and without anthracycline treatments ($p=0.1446$). However, anthracycline remained associated with more diabetes [hazard ratio (HR): 1.59; 95% confidence interval (CI): 1.05–2.39; $p=0.0278$] after adjustment for age, gender, and comorbidities. Moreover, cumulative anthracycline doses of 253-400mg (HR: 1.94; 95% CI: 1.23–3.05; $p=0.0043$) and 401-504mg (HR: 1.83; 95% CI: 1.11–3.01; $p=0.0180$) increased the incidence density of diabetes in a dose-dependent manner ($p=0.0438$). Notably, patients with and without anthracycline treatment had similar yearly adapted diabetes complications severity index alteration (0.58±1.89 *vs* 0.75±1.85; mean±standard deviation), suggesting anthracycline did not deteriorate outcome of diabetes in B cell lymphoma patients ($p=0.4924$).

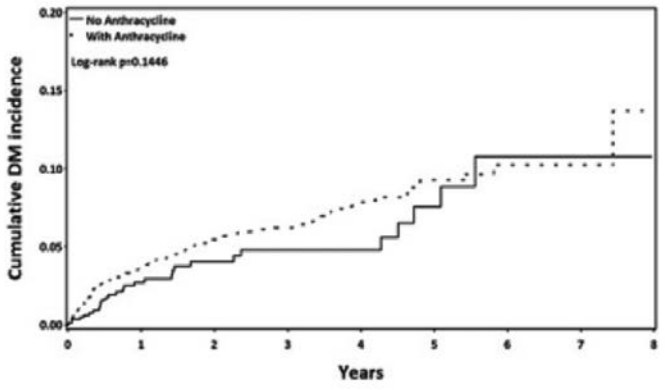

Figure 1.

Summary/Conclusions: Anthracycline therapy was responsible for more diabetes in B cell lymphoma in a dose-dependent manner. More intensive blood sugar monitoring and control should be recommended to B cell lymphoma patients, especially those who received anthracycline treatment.

E1475

THE COST-EFFECTIVENESS OF LENALIDOMIDE PLUS DEXAMETHASONE FOR THE TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA IN CHINA

J. Lu[1,*], S. Hu[2], P. Xu[3], Y. Feng[4]
[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, [2]Fudan University School of Public Health; Shanghai Health Development Research Center, [3]Celgene China, Shanghai, [4]Department of Pharmacy, Beijing Hospital, Beijing, China

Background: The introduction of lenalidomide plus dexamethasone (RD), and bortezomib-contained regimens, has improved the management of relapsed or refractory multiple myeloma (rrMM) in China. However due to the absence of both head-to-head (direct) comparative efficacy and local economic data, stakeholders still face hard choices to make when choosing one therapy over another. Indirect treatment comparisons and health economic modeling can help support local decision-making by enabling the incorporation of country-specific unit cost data, in the comparison of cost-effectiveness of one treatment *vs* another where treatments have not been directly compared in clinical trials.
Aims: To assess the cost-effectiveness of RD relative to bortezomib/dexamethasone (VD) and bortezomib/cyclophosphamide/dexamethasone (VCD) for rrMM in Chinese patients.
Methods: The Markov-based decision analytic model was constructed to simulate lifetime health benefits and direct medical costs associated with RD, VD, and VCD for rrMM in Chinese patients. A systematic literature review was conducted (in both Chinese and English databases, from 2005 to 2016) to obtain efficacy data of the three treatment regimens. The risk of progressive disease associated with RD and VD were estimated from available Chinese trials. The efficacy of VCD and the mortality associated with progressive disease after treatments with RD and VD were lacking in China, therefore were estimated from the published international randomized clinical trials. Published quality of life data was adapted to Chinese rrMM patients with health utility adjustment. The model took into account (i) drug acquisition costs, (ii) treatment administration costs derived from Chinese urban claims data, (iii) serious adverse events management costs based on a survey of seven MM centers across China, and (iv) rrMM management costs estimated from a Chinese real-world hospital setting. Quality-adjusted life years (QALY) and direct medical costs in the model were discounted at 3% per annum. Base case analysis calculated incremental cost-effectiveness ratio (ICER) per QALY for RD relative to VD and VCD, respectively from the Chinese healthcare payer's perspective. One-way sensitivity analysis and probabilistic sensitivity (PSA) with 5,000 Monte Carlo simulations assessed the impact of the model uncertainty on the cost-effectiveness of RD. A scenario analysis was conducted by meta-analyzing the published international randomized trials for the efficacy associated with RD, VD, and VCD, to verify the base case analysis.
Results: Based on the model simulation without discounting survival outcomes over a lifetime horizon, RD could obtain longer average PFS years than VD (2.37 *vs* 0.78) and VCD (2.37 *vs* 1.36). RD was associated with longer discounted QALY (3.06 *vs* 1.58 *vs* 1.41) and more discounted lifetime medical costs (¥494,060 *vs* ¥272,135 *vs* ¥ 244,220) than both VD and VCD. The ICERs per QALY for RD relative to VD (¥149,706) and VCD (¥150,774) were less than the cost-effectiveness threshold of China (three times of estimated 2016 China GDP per capital ¥166,920/QALY, ¥1= €0.138). The cost-effectiveness of RD relative to VD and VCD was mainly driven by the mortality risk associated with the progressive disease after treatment. The scenario analysis generated comparable ICER per QALY associated with RD relative to VD (¥120,974) and VCD (¥117,191), therefore supports the robustness of base case analysis.
Summary/Conclusions: The local data-based health economic model estimates that RD could gain longer PFS and OS with acceptable cost-effectiveness, when compared to VD and VCD in Chinese rrMM patients.

E1476

DEVELOPMENT OF A NEW HAEMATOLOGICAL MALIGNANT PATIENT-REPORTED OUTCOME MEASURE FOR USE IN CLINICAL PRACTICE: HM-PRO

P. Goswami[1,*], S. Salek[1], T. Ionova[2], E. Oliva[3], A.K. Fielding [4], M. Karakantza[5], S. Al-Ismail[6], G.P. Collins[7], S. McConnell[5], C. Langton[5], D.M. Jennings[8], R. Else[9], J. Kell[10]
[1]School of Life and Medical Sciences, University Of Hertfordshire, Hatfield, United Kingdom, [2]National Medical Surgical Centre and Multinational Centre for Quality of Life Research, St Petersburg, Russian Federation, [3]Haematology Unit, Azienda Ospedaliera, Reggio Calabria, Italy, [4]UCL Cancer Institute, London, [5]Leeds Teaching Hospitals NHS Trust, Leeds, [6]Singleton Hospital, ABM University Health Board, Swansea, [7]Oxford University Hospitals NHS Trust, Oxford, [8]Royal Surrey County Hospital NHS Foundation Trust, Guildford, [9]Patient Research Partner, Milton Keynes, [10]Cardiff and Vale University Health Board, Cardiff, United Kingdom

Background: Health-related quality of life (HRQoL) of patients with haematological malignancy (HM) is greatly affected by the disease and the treatment and this has not been captured in a systematic manner in routine clinical practice.
Aims: The aims of this study were to identify issues important to patients with HM and development of a new patient reported outcome measure for use in daily clinical practice.
Methods: A conceptual framework was developed using preliminary literature search and discussions with physicians and patients. Patients with HM were then interviewed to produce a comprehensive item pool reported important by them. The generated items were then discussed in the data definition panel meeting to be included in the prototype version of the HM-PRO. Subsequently, a panel of experts and a panel of patients were asked to rate the items of the prototype HM-PRO for its language clarity, completeness, relevance and scaling followed by cognitive interviews with the patients to pilot test the HM-PRO.
Results: The preliminary literature search revealed that there is no PRO specifically developed for patients with HM for use in daily clinical practice. The conceptual framework comprised of two main themes: QoL (impact); and symptoms. 129 patients (male=76; mean age=61.1 years; SD=15.3; median age =64.9 years; age range =18-88 years; diagnosis –AML, ALL, CML, CLL, MM, ANHL, INHL, HL, MPN, and MDS) with mean duration of the HM of 3.6 years (SD=4.3; and range= 19 days-23 years) from 5 haematology centres were interviewed to identify the issues important to HM patients. A prototype version of HM-PRO was developed after data definition panel meeting with 34 items in impact category (Part A) and 23 items representing disease symptoms (Part B). Nine- member panel of experts and 7-member panel of patients, rated the items and discussed them for its language clarity, completeness, relevance and scaling to reach consensus. 60 patients (male=36; mean age=63.8 years; SD=16.61; median age =69.2 years; and age range =18-91 years) with mean duration of the HM of 4.9 years (SD=6.4; and range= 14 days-26 years) were recruited for the pilot testing where 34 of which were involved in cognitive interviews. 92% of the patients reported that the statements were easy to understand and all issues important to them were covered; 95% stated that they were able to respond spontaneously and expressed their willingness to complete the instrument during their visit to the clinic; 97% reported that the statements were easy to read; 98% did not wish to delete any item; and 88% did not see the need to add any item.
Summary/Conclusions: The findings of the content validation, pretesting and cognitive interviews indicate that HM-PRO possesses a strong content validity in different HMs, includes all the issues important to these patients and the statements are easy to read, understand and respond to spontaneously. HM-PRO will undergo further psychometric testing to support its psychometric properties across different types of HMs.

E1477

OVARIAN TISSUE CRYOPRESERVATION IN PEDIATRIC AND ADOLESCENT PATIENTS UNDERGOING CANCER CHEMOTHERAPY AND/OR HEMATOPOIETIC STEM CELL TRANSPLANTATION

A. Kinoshita[1,*], R. Ooyama[1], D. Keino[1], Y. Matsuoka[1], Y. Koto[1], T. Mori[1], S. Takae[2], N. Suzuki[2]
[1]Pediatric Hematology/Oncology, [2]Department of Obstetrics and Gynecology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Ovarian tissue cryopreservation (OTC) and subsequent reimplantation is the only option available for fertility preservation in prepubertal females, but this approach remains unestablished in pediatric and adolescent patients with cancer. After the experience of OTC for more than 200 patients with primary ovarian failure and more than 50 patients with breast cancer in our center over 5 years, we have started OTC for pediatric and adolescent cancer patients since 2015.
Aims: To define safety and benefits of OTC in pediatric and adolescent patients with undergoing cancer chemotherapy and/or hematopoietic stem cell transplantation.
Methods: From December of 2015 to February of 2017, OTC was performed in 6 girls (median age 14 years, range 11-15): 2 patients with myelodysplastic syndrome, 2 with lymphoma, 1 with acute lymphoblastic leukemia, and 1 with primary immunodeficiency. Indications for OTC were 5 hematopoietic stem cell transplantation and 1 sterilizing chemotherapy. Two patients with myelodysplastic syndrome and 1 with immunodeficiency received no previous chemotherapy and the other 3 had received prior chemotherapy. Laparoscopy was used to collect one of a pair of ovarium that was frozen by vitrification method.
Results: Ovarian tissue was successfully collected from the 6 patients studied without major postoperative complications and this procedure did not delay chemotherapy or hematopoietic stem cell transplantation. Histological analysis of ovarian tissue revealed primordial follicles, even in the patients with previous cancer chemotherapy. No malignant cells were identified. Median post-harvest

follow-up was 9 months (0-14) and all patients were alive. Hormonal results were evaluable for 3 patients: 2 patients were in premature ovarian insufficiency. Re-implantation of ovarian tissue has not yet been performed.
Summary/Conclusions: Although OTC and subsequent re-implantation is experimental, this approach may be the best method for restoration of ovarium function and fertility preservation in pediatric and adolescent cancer patients. A risk of reseeding malignant cells is a problem still to be conquered.

E1478

A MULTI-DISCIPLINARY APPROACH TO CHEMOTHERAPY PRESCRIBING AT NEWCASTLE UPON TYNE HOSPITALS NHS FOUNDATION TRUST
S. Gabriel[1,*], G. Jones[2], C. Cox[2], S. Blakey[2], M. Lannon[2]
[1]Northern Centre for Cancer Care- Pharmacy, [2]Northern Centre for Cancer Care-Haematology, Newcastle upon Tyne Hospitals NHS Trust, Newcastle upon Tyne, United Kingdom

Background: Newcastle Upon Tyne Haematology service has made numerous changes in recent years to provide streamlined care for patients, focusing on reduced wait times & improve quality of care. The original pathway was costly in time, involving several waits for the patient: for urgent venepuncture, physician consultation, prescribing of chemotherapy, specialist pharmacist screening of prescriptions & then a separate trip to pharmacy for dispensing. Patients then returned home & waited for a call from the Clinical Nurse Specialist (CNS) to confirm if blood results were appropriate for chemotherapy administration. If a dose adjustment was required the drug was wasted & patients needed to return to hospital for another prescription. Pharmacy waiting times for oral outpatient chemotherapy or supplementary medications are approximately 30 minutes.
Aims: We introduced a weekly multi-disciplinary chemotherapy prescribing meeting in 2013 with the aims of improving prescribing safety; minimising time spent prescribing in clinic & reducing patient waiting times. Present at each meeting is a Haematology Specialist Pharmacist, Haematology CNS, Consultant & Specialist Registrar. Chemotherapy is planned a week in advance on ChemoCare (an electronic chemotherapy prescribing package). Chemotherapy is prescribed & immediately screened by the pharmacist; oral chemotherapy is collected from pharmacy by a CNS prior to clinic. All prescription queries are resolved during this meeting. Deferred oral chemotherapy can be returned to pharmacy stock, minimising waste. Intravenous chemotherapy is pre-planned with authorisation on the day of treatment if the patient is fit to proceed.
Methods: In the latest update to the care pathway, we focused on delivery of care to myeloma patients receiving oral chemotherapy, including setting up a nurse-led clinic. Data have been collected to assess service impact, particularly on patient satisfaction. The latter was assessed using a patient survey. Between July-Dec 2014, 66 patients received oral chemotherapy in the Myeloma Consultant-led clinic, Lenalidomide based regimens accounted for 86% of the oral regimens prescribed. On average, 7 patients per week were on maintenance therapy. During this period 8% of chemotherapy courses were deferred due to low blood counts or side-effects. Drugs were not wasted due to the pharmacy agreement.
Results: A patient satisfaction survey was undertaken from Jan-June 2015, post-introduction of the nurse-led clinic paired with the MDT chemotherapy prescribing meeting. Patients were asked about a wide-range of quality parameters. Results showed 89% of patients noted a reduction in wait times & 89% felt they spent more time in consultations as a result. All patients noted they spent more time with the nurse specialist & benefited from not attending pharmacy. All patients rated the service as more efficient.
Summary/Conclusions: The MDT approach to prescribing & dispensing oral chemotherapy & supportive medication has streamlined our way of working & led to greater efficiency for both staff & patients. The new model has changed how patients are seen & assessed and minimised drug wastage, an issue incurred in the old system. However, it must be noted that during Jan-June 2015 the cost of wasted drug, due to patients being unfit for treatment on the day, potentially incurred by pre-prescribing was £57,775. It is, therefore, critical to ensure that medication that has not yet been given to patients can be returned to pharmacy if this type of pre-prescribing model is to operate efficiently.

E1479

FINANCIAL TOXICITY OF THE MANAGEMENT OF MULTIPLE MYELOMA
B. Sidi Mohamed El Amine[1,*], H. Asma[1], O. Fouzia[1], S.A. Najet[1], Z. Zahia[1]
[1]Hematology department, Universitary hospital of Sidi Bel Abbés, Sidi Bel Abbes, Algeria

Background: Advances in supportive care and the development of novel treatments have helped to double the life expectancy of patients with newly diagnosed multiple myeloma (MM). Financial toxicity is increasingly recognized as adversely affecting the quality of life and medication adherence, and patients with MM might be particularly vulnerable because of extended treatment duration.
Aims: Our aim was to measure financial toxicity and its effects on patients undergoing treatment for MM.
Methods: Between October 2016, and January 2017, we did a cross-sectional survey of individuals receiving at least 3 months of ongoing treatment for MM at our department. The survey included the 11-item COST measure (financial toxicity score range 0-44). A paper survey was offered to eligible patients on arrival for routine follow-up visits or treatment, and participants were asked to complete the survey before or after their visit or stay in day hospital. The data were postponed by two psychologists. The COST questionnaire was validated with internal consistency (Cronbach's coefficient) and item correlation (Pearson's r coefficient) tests, especially those of Quality of life (EORTC QLQ 30).
Results: Of 47 patients approached for the study, 44 individuals completed the survey and 40 (91%) were insured. Analysis of the internal consistency of the COST questionnaire showed an overall Cronbach's alpha coefficient of 0, 84. According to COST data, 26 (59, 1%) patients have a score<22. Patients with financial difficulties have a negative impact on their quality of life (P=0, 02, r=0, 32), and low scores of physical and role functioning (P<0,001, r >0, 5). 29 (66%) patients feel financially stressed, and 23 (52, 3%) did not control their financial situation. After a logistic regression, lower household income (P=0,009) and Poor response to treatment (P=0, 0037) were associated with higher financial burden as measured with the COST score.
Summary/Conclusions: Despite insurance and free care, financial toxicity is common in many myeloma patients, especially those with lower income and refractory disease. Strengthened collaboration among patients and health-care stakeholders is needed to promote healthcare reforms that promote high value and affordable myeloma care.

E1480

THE IMPLICATIONS OF NON-PROPORTIONAL HAZARDS FOR THE MEASUREMENT OF SURVIVAL BENEFIT IN HEALTH TECHNOLOGY ASSESSMENT: CURRENT APPROACHES AND THE ROLE OF RESTRICTED MEAN SURVIVAL TIME
G. Monnickendam[1,*], J. McKendrick[1], M. Zhu[1], Y. Su[2]
[1]PRMA Consulting, Fleet, United Kingdom, [2]Global Health and Value, Pfizer, New York, United States

Background: Median survival and hazard ratios (HR) calculated from Cox proportional hazard (PH) models for progression-free survival (PFS) and overall survival (OS) are principal survival endpoints in oncology clinical trials. The advent of novel agents, including immuno-oncologics, has seen increasing reports of non-proportional hazards (non-PH). When non-PH are present, it is challenging to evaluate the true clinical significance of survival differences expressed as median and HR since these measures do not represent the comparative benefit over the full period of observed data. In such situations, additional metrics such as restricted mean survival time (RMST) may be valuable.
Aims: To determine current methods used by health technology assessment (HTA) agencies when non-PH are observed in assessments of hematology/oncology drugs, and the extent to which RMST is accepted as an alternative measure of treatment benefit in these circumstances.
Methods: Methodological guidelines published by 10 HTA agencies in 8 major developed countries (Australia, Canada, France, Germany, Italy [Emilia Romanga, Veneto], Spain, Sweden, and the United Kingdom [NICE, SMC]) and by influencing organizations in the US (including the Institute for Clinical and Economic Review, ICER) were reviewed to establish recommended approaches for presenting survival benefit from clinical trials, particularly the use of RMST where non-PH were reported. To determine how these guidelines are implemented in practice, published HTA reports were examined across the 8 countries for 23 oncology agents (including 4 in hematology) approved by the FDA and EMA since 2014, to identify instances where testing for non-PH was conducted and RMST data reported.
Results: Guidelines from only 2 agencies (PBAC in Australia and NICE in the UK) described formal testing for non-PH. Testing was reported in 15 (of 23) NICE assessments and 4 (of 10) PBAC assessments. For the hematology drugs, non-PH testing was conducted in 3 (of 4) NICE assessments; it did not hold in 2 instances. Of the agencies (from France, Germany, Italy and Spain), which focus on comparative clinical benefit, only 1 (GENESIS in Spain) discussed the concept of RMST in their guidelines; 5 (of 45) assessments from these countries included RMST. Of the agencies (from Australia, Canada, Sweden, and the UK) which focus on cost-effectiveness, all except the TLV in Sweden include RMST in their guidelines; RMST was reported in 13 (of 81) HTA assessments from those countries. Of the 3 hematology drugs where non-PH was tested within the NICE process, only one (ofatumumab, where there were PH) reported RMST (utilized during economic model sensitivity analyses). Non-PH is not a widely reported issue in US guidelines; however, the ICER has acknowledged it and PH testing was conducted in both ICER reports in oncology.
Summary/Conclusions: Testing for non-PH is not widely reported in clinical trials or incorporated into assessments by HTA agencies except by UK NICE. RMST as a metric to assess OS has played a role in assessing clinical benefit within the context of HTA assessments, although not consistently within countries (across drugs) or across countries (for the same drug), as was seen with the hematology agents. As treatments for cancer expand to new classes and indications, instances of non-PH will likely increase; alternative survival metrics such as RMST may have an increasingly important role to play in describing survival benefit in such cases.

Sickle cell disease

E1481

DISEASE SEVERITY AND SLOWER PSYCHOMOTOR SPEED IN ADULTS WITH SICKLE CELL DISEASE

E. Novelli[1,*], D. Jorgensen[2], A. Metti[2], M. Butters[2], C. Rosano[2]
[1]Medicine, Vascular Medicine Institute, University of Pittsburgh, BST E1240, 200 Lothrop St., [2]University of Pittsburgh, Pittsburgh, United States

Background: Psychomotor slowing is common in children with sickle cell disease (SCD), but little is known about its severity in adult patients. While the primary risk factor for psychomotor slowing is stroke, there has been mounting evidence that cognitive impairment also occurs in patients without a history of overt or silent stroke. Risk factors for cognitive impairment in patients with SCD without stroke are, however, not completely known, particularly in relationship to the SCD genotype.
Aims: We conducted a cross-sectional study to quantify psychomotor slowing, measured with the Digit Symbol Substitution Test (DSST), a pencil and paper test of executive function, in relationship with disease severity in adult patients with SCD attending an outpatient clinic. We also examined whether demographic, behavioral, physiologic, and pathologic factors that are known to be related to SCD severity and cognitive function in other settings are also related to psychomotor speed in these patients.
Methods: Genotype was used to group patients with SCD (n=88, age: 36.3 years, 33 males) in "severe" (homozygous for the mutated sickle hemoglobin HbS [HbSS], or compound heterozygous with β^0 thalassemia [HbS/β^0]) or "moderate" groups (compound heterozygous for HbS, with either HbC [HbSC], or β^+thalassemia [HbS/β^+]). Standardized DSST scores based on published norms were used to define mild cognitive impairment, defined as ≤1.5 standard deviations (SD) below the DSST T-score (T-scores had a mean of 50 and SD of 10). Data on demographics, hematological parameters, hydroxyurea and opiate intake, stroke (including silent cerebral infarcts (SCI)) and transfusion history were collected concurrently with DSST. Analyses were repeated after exclusion of patients with a history of stroke (n=12). Age-adjusted p-value was calculated with logistic regression for all variables except age (unadjusted) and DSST T-score (already adjusted for age, sex and education in calculation of T-score).
Results: Among our patients, 56 (63%) had a "severe" genotype and 32 (27%) had a "moderate" genotype. Mild cognitive impairment was detectable in both the "severe" and the "moderate" group (30% and 9%, respectively, age-adjusted p=0.15). Compared to the "moderate" group, those in the "severe" group, had significantly lower DSST scores (age, sex and education adjusted p value=0.006), independent of adjustment for factors that differed between groups: hemoglobin, ferritin, hydroxyurea use, blood pressure parameters and stroke history. Results were similar after excluding patients with stroke.

Table 1.

Table 1. Predictor variables of interest

	"Severe"	"Moderate"	P†
Age (years)	33.7 (10.8)	40.9 (12.8)	**0.009**
Male sex*	21 (37.5%)	12 (37.5%)	1.00
Education (years)	13.1 (1.8)	13.2 (1.7)	0.80
Mild Cognitive Impairment*	17 (30.4%)	3 (9.4%)	0.14
DSST T-score	47.6 (14.5)	51.0 (13.4)	**0.006**
O^2 Saturation (%)	97.5 (1.8)	98.1 (1.7)	0.14
WBC count (X 10^9/L)	9.7 (3.8)	9.2 (3.7)	0.87
Hemoglobin (g/dL)	9.2 (1.5)	11.5 (1.5)	**<0.0001**
Platelet count (X 10^9/L)	344.1 (179.8)	263.3 (115.1)	0.16
Reticulocytes (%)	1.7 (4.0)	1.1 (1.9)	0.51
LDH (IU/L)	321.2 (142.3)	269.2 (149.1)	0.18
Ferritin (ng/mL)	1141.6 (1864.4)	403.4 (1042.2)	**0.05**
Creatinine (mg/dL)	0.7 (0.3)	0.8 (0.2)	0.91
SBP (mm/Hg)	111.3 (13.4)	118.9 (13.6)	0.08
DBP (mm/Hg)	68.8 (7.7)	73.5 (9.8)	**0.02**
MAP (mm/Hg)	83.1 (8.4)	88.6 (10.0)	**0.03**
Hydroxyurea use*	32 (57.1%)	10 (31.2%)	**0.04**
Opiate use*	15 (26.8%)	10 (31.2%)	0.57
Transfusion history*	17 (31.5%)	5 (16.1%)	0.15
Stroke history*‡	10 (18.2%)	2 (6.2%)	0.08

* Mean (SD) unless otherwise noted. † Age-adjusted p. ‡ Includes SCI

Summary/Conclusions: Psychomotor slowing in SCD differs in relationship to genotype; this difference appears unrelated to history of stroke or severity of anemia and other risk factors examined cross-sectionally. Although relatively infrequent, mild cognitive impairment was also detectable in patients with a less severe genotype. Longitudinal studies of SCD should include all diseases genotypes, and examine factors that would reduce the risk of cognitive impairment in each subgroup.

E1482

MONITORING OF CHRONIC HEPATIC DAMAGE IN SICKLE CELL DISEASE: LONGITUDINAL OBSERVATION OF A COHORT OF ADULT PATIENTS

V.M. Pinto[1], B. Gianesin[1], M. Balocco[1], P. Carrara[1], G.L. Forni[1,*]
[1]Haematology-Centro Microcitemia Anemie Congenite, Ospedale Galliera Genova, Genova, Italy

Background: Acute vaso-occlusive events (VOCs) in Sickle Cell Disease (SCD) is an important cause of hepatic damage which can result in catastrophic consequences as acute hepatic failure and contribute to early mortality. In addition, sickle hepatopathy may be the consequence of SCD's treatment as liver iron overload or viral hepatitis due multiple blood transfusions that these patients require in their lifetime. Therefore both SCD itself and related therapies may lead liver to fibrosis/cirrhosis.
Aims: We evaluated liver fibrosis using Transient Elastography (TE) in patients with SCD, exploring possible correlation with clinical, laboratory and imaging findings in longitudinal way.
Methods: SCD patients with at least one stiffness evaluation were retrospectively evaluated in the decade 2006-2016 using biochemical markers (liver damage, cholestatis, liver syntetic capacity, iron overload, viral hepatitis and hemolitytic index), TE and liver imaging (ultrasound, MRI-R2*).
Results: 37 adult patients were evaluated: 32% HbSS, 68% HbSβ°, median 39yrs, 46% male, median stiffness 6.6 KPa IQR: 5.1-9.1 KPa (Table). There were not differences of stiffness value for gender, genotype. A positive moderate correlation was observed between TE and serum ferritin values (Rp=0.43, p=0.008), ALT (Rp=0.42, p=0.01), AST (Rp=0.49, p=0.0022), conjugated bilirubin (Rp= 0.59, p<0.001), ALP (Rp=0.51, P=0.002); a positive strong correlation was observed between TE and GGT (Rp=0.79, p< 0,001), negative moderate correlation with the albumin (Rp=-0.47, p=0.0048). We found that the group of patients on eritroexchange programmes had a value of stiffness lower than the group transfused (p=0.007). No significant correlation was found between stiffness and LIC (Rp=0.11, p=0,67). For 24 patients all record were available at time of first observation until last follow up (f.u.): 75% HbSβ°, median age 39.5yrs, male 42%, median f.u. 6 yrs, median stiffness 7.3 KPa IQR: 5.3-11.9 KPa. At the first evaluation we documented a significative positive-moderate correlation of TE with serum ferritin (Rp=0.43, p=0,037), AST (Rp=0.54, p= 0,006), conjugated bilirubin (Rp=0.52 values 0,009) and positive-strong correlation with GGT (Rp=0.68, p<0,001); these parameters except of ferritin (Rp=0.3, p=0.15) and AST (Rp=0.39, p=0.058) have maintained the correlation with last f.u.; albumin and ALP showed a significant strong correlation only at f.u. (albumin Rp=-0.64, p=0.004; ALP Rp=0.7, p=0.0017). To remove factors associated with liver fibrosis we also conducted this analysis in the subset of patients HCV negative without liver iron overload: 26 patients, HbSβ° 73%, median age 40.5yrs, male 50%, median f.u. 6 yrs, median values of stiffness 6.1 KPa IQR: 4.6-7.4 KPa. All significant correlations previously described were confirmed also in this group. Three patients in this cohort presented stiffness value according to F4 METAVIR since their first evaluation: all these patients showed pauci-symptomatic disease in terms of VOCs, however they had a severe hepatic damage due to sickle cell disease.

Table 1.

Table Mean characteristics of the 37 patients

	median	IQR
Age (yrs)	39.0	30-50
BMI (kg/m2)	23.1	20.3-25.7
Hb (g/dL)	10,0	9.3-10.7
AST (IU/L)	35.2	26.8-50.4
ALT (IU/L)	25,0	19-36.3
GGT (IU/L)	27.4	17.8-51.7
Total bilirubin (mg/dL)	1.9	1.4-3.0
Conjugated bilirubin (mg/dL)	0.63	0.5-0.75
Ferritin (ng/mL)	670	320-1146
ALP (IU/L)	87.3	68.3-109.7
Albumin (g/L)	4.2	4.0-4.3
Prothrombin Time Activity %	84.4	79.1-89.9
LDH (IU/L)	617	505-869
Reticulocytes (%)	6.45	3.9-10.9
Hb Fetal (%)	5.6	1.9-13.5
T2* (ms)	8.6	6.7-13.7

Summary/Conclusions: Early identification of chronic hepatic disease sometimes pauci-symptomatic in terms of VOCs but able to lead to advanced stage and progressive fibrosis is crucial for suitable clinical management to avoid cirrhosis in SCD patients. The combination of TE with specific serum markers (GGT, ALP, albumin) is a valid tool to early detection of sickle hepatopathy.

E1483

MICROSTRUCTURAL ANALYSIS OF RETINO-CHOROID LAYERS USING OPTICAL COHERENCE TOMOGRAPHY IN ADULT PATIENTS WITH SICKLE CELL DISEASE

G. Graziadei[1,*], L. Dell'Arti[2], G. Barteselli[3], F. Viola[4], L. Riva[2], E. Carini[5], S. Francomm[3], A. Invernizzi[6], L. Duca[7], M.D. Cappellini[8]

Background: Retinopathy is one of the ophtalmological complications of patients with Sickle cell disease (SCD), due to microvascular occlusions; occasionally, proliferative sickle cell retinopathy (PSR) can lead to severe vision loss.
Aims: a. to analyze macular alterations in patients with Sickle Cell Disease (SCD) by spectral-domain optical coherence tomography (SD-OCT), using the automated software for retinal segmentation; b. to investigate relationship between OCT abnormalities and the severity of proliferative sickle cell retinopathy (PSR); c. to elucidate the role of potentially contributory systemic factors on the development of macular thinning.
Methods: This is a prospective, observational case-control study. Ophthalmological evaluation, fluorescein angiography and SD-OCT were performed. Central and temporal retinal layers were measured by the SD-OCT Automatic Segmentation software. SCD eyes were divided into two groups based on the presence of visible macular thinning areas. Clinical data and blood samples were collected.
Results: Thirty consecutive adult SCD outpatients were studied (median age 38.7±9.89 (M:F 12:18), including 9 patients with Sickle Cell Anemia (SCA), 17 with Sickle Cell β°-Thalassemia and 4 HbS/HbC. One HbS/HbC eye was not considered due to retinal detachment and severe refractive defect. Nineteen out of 59 eyes (32.2%) and 13 out of 30 SCD patients (43%) were noted to have patchy areas of macular thinning on SD-OCT, mostly seen temporally to the fovea. Among these patients, 6 had SCA, 4 had β°-Thalassemia and 3 HbS/HbC. More severe PSR was present in 16/59 eyes (29%); the prevalence of temporal macular thinning was higher (10/16) in eyes with more severe PSR (62.5%). Both inner and outer retinal layers thinning of the foveal region and of the central and temporal macula was found in the overall SCD patients compared with normal controls ($p<0.0001$). SCD eyes with patchy retinal thinning showed a significant reduction of inner nuclear layer (INL) and outer plexiform layer (OPL) in the temporal region. Univariate analysis revealed a significant correlation between patchy areas of severe retinal thinning on OCT and SCD need for transfusions, need for chelation, HbF, ferritin, and transferrin saturation (p-value<0.10). However, the most predictive variables for retinal thinning as assessed after multivariate regression analysis were the need of chelation ($p=0.0187$) and the HbF ($p=0.0775$). More specifically, the odds of retinal thinning is 94.2% lower when chelation is present, and the odds of retinal thinning decreases by 12.9% when HbF increases by 1 unit.
Summary/Conclusions: In this study SCD eyes of all patients showed both inner and outer retinal thinning in the central and temporal macula. Ischemia caused by chronic occlusion of the deep and superficial capillary plexus could explain the different retinal layers' damage and the pattern of thinning. No major statistical differences were found between the three sickle genotypes because of small sample. Because severe retinal thinning affects visual function and can lead to irreversible visual loss, regular ocular checkups are essential for SCD patients.

E1484

NON ABLATIVE TRANSPLANT CONDITIONING WITH TREOSULFAN IS CURATIVE IN A MURINE MODEL OF SICKLE CELL DISEASE

D. Devadasan[1,*], C.-W. Sun[2], T. Townes[2], F. Goldman[3]
[1]Pathobiology and Molecular Medicine theme, Department of Graduate Biomedical Sciences, [2]Department of Biochemistry and Molecular Genetics, [3]Department of Pediatrics, University of Alabama at Birmingham, Birmingham, United States

Background: Hematopoietic stem cell transplantation (HSCT) for patients with sickle cell disease (SCD) is curative, though significant toxicity from myeloablative conditioning is limiting. We have previously developed knock-in mice producing normal (AA) or sickle (SS) human hemoglobin recapitulating severe anemia, hyposthanuria and limited lifespan found in SCD. Reduced-intensity conditioning regimens decrease transplant toxicity and are preferable in non-malignant disorders. Novel approaches have been proposed including targeted depletion of stem cells (ACK2), co-stimulation blockade (anti-CD40L), and combination therapy with less toxic alkylating agents (Treosulfan).
Aims: Optimize non-myeloablative conditioning in a murine model of SCD that allows for sufficient donor RBC chimerism.
Methods: Control (AA) and SCD (SS) animals were treated with varying conditioning regimens (+/- rescue with AA or SS marrow), including Treosulfan (2-5g/kg), ACK2 (100-500ug), anti-CD40L, and low-dose radiation, alone or in combination. Short and long-term toxicities, including survival, were monitored over a 12 month period. Hematologic effects were determined by assaying CBCs, reticulocytes, bone marrow (BM) cellularity and RBC chimerism (isoelectric focusing). Myeloid/lymphoid chimerism was monitored by FACS combined with droplet-digital PCR. Renal tubular function was assessed by measuring urine osmolality, and moribund animals underwent necropsy to assess organ damage.
Results: Erythroid hyperplasia was noted in the BM of SS, relative to AA mice. Treosulfan, in a dose-dependent manner, decreased BM cellularity and induced cytopenia in AA and SS mice. AA mice were able to tolerate Treosulfan at non-myeloablative doses of 6g/kg. In contrast, SS mice were unable to tolerate doses of 3g/kg unless RBC transfused by d+3. At 3g/kg dose, erythroid engraftment was transient in SS transplanted mice and most often absent by 2 months post-transplant, with only 25% of animals having sustained RBC chimerism at one year. In SS mice achieving 50% AA in peripheral blood, fertility was preserved, urine osmolality normalized and organ pathology was comparable to age-matched controls. ACK2, anti-CD40L, or low-dose radiation, in combination with Treosulfan (3g/kg), failed to improve engraftment. In contrast, increasing Treosulfan to 3.6g/kg resulted in donor-erythroid chimerism at 3 months post-transplant in all mice, with improvement in hematologic parameters and normalization of hyposthanuria. These animals are currently being observed for fertility, organ toxicity and survival.
Summary/Conclusions: SCD mice closely mimic human disease in phenotype and ablative conditioning intolerance. Treosulfan, at sub-myeloablative dosing, sustained erythroid chimerism and reversed the SCD phenotype. Our data suggests that pre-transplant conditioning with Treosulfan alone may be permissive for engraftment, in an allogeneic and gene-corrected autologous clinical transplant setting.

E1485

SILENT CEREBRAL ISCHEMIA AND THROMBOEMBOLIC EVENTS IN SICKLE CELL DISEASE: ANALYSIS OF COAGULATION PARAMETERS AND THROMBOELASTOGRAPHY

M. Dimopoulou[1,*], M. Politou[2], K. Stavroula[1], D. Koutsouri[2], P. Tsioutsias[1], P. Flevari[1], E. Voskaridou[1]
[1]Thalassemia and Sickle Cell Disease Center, Laikon General Hospital, [2]Hematology Laboratory, Blood bank, Aretaieion Hospital, Athens, Greece

Background: The complications of Sickle Cell Disease (SCD) include stroke and silent cerebral infarcts (SCI). The increased incidence of thromboembolic events in SCD has only recently been recognized. Apart from red cell sickling other pathogenetic mechanisms have been proposed but they have not been clarified completely. Coagulation factors have been analysed in several studies in SCD but very limited data exist about global coagulation assays such as thromboelastography, which evaluates the contribution of platelets, coagulation factors and cellular elements in clot formation.
Aims: The aim of the present study was to assess the incidence of cerebral ischemia and TEEs in SCD patients and to investigate their pathophysiology with analysis of coagulation parameters, including thromboelastography.
Methods: 61 adult SCD patients were included in the study and underwent brain MRI. Measurements of fibrinogen, D-Dimers, antithrombin III, proteins S and C were performed (SIEMENS BCS) and thromboelastography ROTEM^R was performed in order to analyse NATEM CT(Closure Time), MCF (Maximum Clot Firmness), EXTEM CT, MCF and FIBTEM CT, MCF. Brain imaging as well as all clotting assays were performed in steady state and not during the course of an acute thrombotic or ischemic event
Results: The median age of the patients was 51 yrs (range 27-70), 40 of them were female and 21 male. Abnormal findings were revealed in the brain MRI of 35/61 patients (57.4%). The findings consisted mainly of microischemic lesions. Only 5/35 patients had a previous history of overt stroke, 1/5 TIA. In the remaining 30/35 patients ischemic lesions were considered SCIs, in the abscence of neurologic manifestations. In 3/5 patients with a previous stroke the size of the infarcts in brain MRI was larger (with maximum diameter up to 4,5 cm). 14/61 patients had a previous history of venous TEE (23%), in 7/14 the event was pulmonary embolism and 2/14 had recurrent TEE. 14/61 (23%) of patients had a previous history of acute chest syndrome (ACS). In total 48/61 patients (78.7%) were already on treatment with hydroxyurea when they underwent the analysis. Elevated platelets were found in 22/61 patients (36%), elevated fibrinogen in

4/61 (1.6%), positive D-Dimers in 57/59 (96.6%), decreased protein S in 10/61(16,3%) and decreased protein C σε 13/61 (21,3%). NATEM MCF was increased in 27/61(44,3%) patients while EXTEM MCF was increased in 31/61(50.8%) patients. Patients with a history of TEE had higher mean values of NATEM-MCF and EXTEM–MCF and those differences were statistically signifinact (p=0.023, and p=0.011 respectively). There was a statistically significant association between the presence of ischemic lesions in brain MRI and the history of previous TEE (p=0.01). On the contrary the history of ACS was not correlated with the presence of ischemic lesions in MRI. Chronic Hydroxyurea treatment did not correlate with the abscence of ischemic findings in brain MRI. Among patients with ischemic lesions those who were already on chronic hydroxyurea treatment had a shorter NATEM-CT compared to patients without treatment. In patients with ischemic lesions in MRI and a history of TEE NATEM-MCF and EXTEM MCF were higher (p=0.03, και 0.03, respectively).
Summary/Conclusions: The presence of microischemic encephalopathy is very common in SCD patients and is associated with a history of TEE, which is also frequent in SCD. There seems to be a permanent activation of the coagulation mechanism in SCD. In SCD patients with SCIs and a history of TEE, apart from clotting factors and natural inhibitors there seems to be a contribution of platelets and cellular elements, possibly sickle cells. The impact of chronic hydroxyurea treatment on the pathogenesis of silent infarcts and TEEs needs further evaluation.

INVASIVE BACTERIAL INFECTIONS IN GAMBIAN PATIENTS WITH SICKLE CELL ANEMIA IN AN ERA OF WIDESPREAD PNEUMOCOCCAL AND HAEMOPHILUS INFLUENZA TYPE B VACCINATION

G. Soothill[1,*], S. Darboe[2], G. Bah[2], L. Bolarinde[2], A. Cunnington[3], S. Anderson[2]
[1]Royal Free Hospital, London, United Kingdom, [2]Medical Research Council Unit Gambia, Fajara, Gambia, [3]Imperial College London, London, United Kingdom

Background: Bacterial infections cause significant morbidity and mortality in patients with sickle cell anemia, especially in populations without reliable access to antimicrobial prophylaxis and treatment. The longstanding use of penicillin prophylaxis and vaccination for *Streptococcus pneumoniae* and *Haemophilus influenzae* type b in resource-rich settings has minimised the additional risk of invasive bacterial infections associated with sickle cell anemia. However, these interventions are not routinely implemented in much of Africa, despite this region having the greatest burden of disease, with over 80% of people with sickle cell anemia born on the continent. The Gambia has well established vaccination programmes for pneumococcal and *Haemophilus influenzae* type b, which is rare in the region. There is little data on the identity of bacterial infections in African sickle cell anemia populations, and we believe (until this study) there were no data from countries with comprehensive vaccination programmes against *Streptococcus pneumoniae* and *Haemophilus influenzae* type b.
Aims: Primary: to determine the predominant pathogens causing invasive bacterial infections in a population of sickle cell anemia patients admitted to the Medical Research Council Unit Gambia. Secondary: to review the characteristics of this sickle cell anemia population.
Methods: A retrospective analysis of the clinical and laboratory records relating to 161 admissions of 126 patients with sickle cell anemia admitted to the Medical Research Council Unit Gambia over a five-year period (between April 2010 and April 2015) when there was high coverage of pneumococcal and *Haemophilus influenzae* type b vaccination.
Results: Pathogenic bacteria were cultured from blood in 11 of the 131 admissions which had blood cultures taken (8.4%, 95% CI 4.5-14.1%). The most frequent organism isolated was *Salmonella typhimurium* (6/11; 54.5%), followed by *Staphylococcus aureus* (2/11; 18.2%) and other enteric Gram-negative pathogens (2/11; 18.2%) and there was one case of *Haemophilus influenzae* non-type b bacteremia (1/11; 9.1%). No cases of bacteremia caused by *Streptococcus pneumoniae* or *Haemophilus influenzae* type b were identified. The most common diagnosis causing the admission was vaso-occlusive crisis (53/161; 32.9%), followed by infective complications including pneumonia (16/161; 9.9%) and osteomyelitis (12/161; 7.5%). The median length of admission was five days and the median age of patients was five years (IQR: 2-13 years). A new diagnosis of sickle cell anemia was made during the admission in just under half of patients.

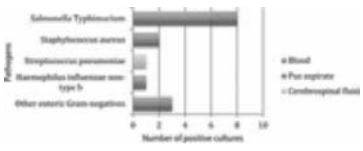

Figure 1.

Summary/Conclusions: The predominance of non-typhoidal *Salmonella* and other enteric Gram-negatives as the causative agents of invasive bacterial infections in our study is striking. Despite its success in resource-rich settings, penicillin may not be the optimal prophylaxis for sickle cell anemia patients already vaccinated for pneumococcal and *Haemophilus influenzae* type b in The Gambia. For sickle cell anemia patients with suspected bacterial sepsis, empirical treatment must be effective against both non-typhoidal *Salmonella* and *Staphylococcus aureus*, and account for local resistance patterns. As other countries in the region adopt pneumococcal and *Haemophilus influenzae* type b vaccination programmes, they may see a change in the spectrum of pathogens found in sickle cell anemia patient populations. Local research may be needed to determine appropriate antimicrobial treatment and prophylaxis regimens for patients with sickle cell anemia.

E1488

THE ASSOCIATION OF IGF-1 AND IGFBP-3 SERUM LEVELS AND GENE EXPRESSION WITH THE PATHOGENESIS OF INFLAMMATION IN SICKLE CELL DISEASE

N. basut[1], F. karahan[2], E. Ak[3], S. Ünal[3,*]
[1]Pediatri, merisin Üniversity Pediatri, [2]Mersin Üniveristy Pediatric Oncology Department, [3]Mersin Üniversity Pediatic Hematology Department, Mersin, Turkey

Background: Sickle cell disease (SCD) is one of the chronic inflammatory diseasesSerum markers of inflammation have provided evidence for a state of chronic inflammation in sickle cell disease (SCD). Inflammation promotes endothelial adherence to sickle erythrocytes.
Aims:. We aimed to investigate the serum insulin-like growth factor 1 (IGF-1) and insulin-like growth factor binding protein 3 (IGFBP-3) levels and gene expression in the pathogenesis of inflammation in sickle cell disease and to determine its role in painful crises.
Methods: A total of 71 patients aged 2 to 18 years, who were followed with the diagnosis of SCD in our department, were included in the study between April 2012 and April 2013. Patients were divided into two groups; Group 1: Patients who had a painful crisis during the study (41 patients, mean age: 11.5 years) and Group 2: Patients who were in steady state during the study (30 patients, mean age: 11 years). Blood samples were taken from the patients for complete blood count, serum levels of C-reactive protein (C-RP), interleukin-1 β (IL-1β), interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), IGF-1, IGFBP-3 and IGF-1, IGFBP-3 gene expression.
Results: When the patients in both groups were compared in terms of serum IGF-1 level; serum IGF-1 levels were normal in all patients (100%) in group 2 and 33 patients (80.5%) in group 1, and the difference was considered to be statistically significant (p <0.001). When the groups were compared in terms of serum IGFBP-3 level; serum IGFBP-3 level in Group 2 was found to be significantly lower in Group 1 (p <0.001). Also, when the patients were examined for IGF-1 and IGFBP-3 gene expression, no significant difference was found between the groups (Table 1). A negative correlation was found between leukocyte level and IGF-1 in group 1, and IGF-1 gene expression and CRP in group 2. Serum IGFBP-3 and IL-6 levels were found to be significantly lower in patients without any painful crisis than those with painful crisis in the last year (p <0.05).

Table 1.

	Group 1 (n:41) Median [min.-max.]	Group 2 (n:40) Median [min.-max.]	P Value
Leukocytes (µ/dL)	14,150 [4,6-33,8]	12,9 [6,9-18,2]	0,376
CRP (mg/L)	4,90 [0,20-159,16]	3,03 [0,36-10,36]	0,067
IL-6 (pg/ml)	11,31 [4,35-160,17]	8,12 [0,10-48,32]	**0,001**
IL-1β (pg/ml)	7,89 [5,71-95,65]	6,84 [5,20-30,76]	**0,018**
TNF-α (pg/ml)	10,75 [4,52-45,28]	7,20 [5,44-11,03]	**0,019**
IGF-1 (ng/ml)	215,07 [37,27-751,82]	231,09 [62,66-550,31]	0,334
IGFBP-3 (ng/ml)	2538,02 [1028,82-5625,40]	1762,11 [124,94-3050,49]	**0,010**
IGF-1 Gene Expression	0,18 [0,00-1,19]	0,27 [0,01-3,71]	0,224

Summary/Conclusions: The clinical manifestations of SCD were thought to be associated only with hemoglobin polymerization for a long time. However, recent studies have shown that SCD is a chronic inflammatory disease. The pro-inflammatory cytokines and IGF are in a state of equilibrium in the human body. It has been reported that IGF-1 plays a major role in the production of NO, which is produced in the endothelium and causes a vasodilatory response, and that it increases antioxidant systems and reduces oxidative stress, thereby decreasing inflammation by reducing pro-inflammatory cytokines. In our study, we found that the serum levels of IGF-1, an important growth factor that has not been studied previously in SCD and has recently been evaluated on the effects of inflammation, decreased in SCD patients with painful crisis compared to patients in steady state. It was also found that the levels of inflammatory cytokines, evaluated during the same period, such as IL-6 and TNF-α increased. In conclusion, IGF-1 was thought to play a role especially in the pathogenesis of acute inflammation in SCD.

E1489

UNIVERSAL NEWBORN SCREENING FOR SICKLE CELL DISEASE: PRELIMINARY RESULTS OF THE FIRST YEAR OF A MULTICENTRIC ITALIAN PILOT PROJECT

M. Martella[1], L. Cattaneo[2], G. Viola[1], S. Azzena[1], A. Cappellari[1], E. Baraldi[3], C. Zorloni[2], N. Masera[2], A. Biondi[2], G. Basso[1], R. Colombatti[1,*], L. Sainati[1]
[1]Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, [2]Pediatric Clinic, Università degli studi Milano-Bicocca-Fondazione MBBM, Monza, [3]Neonatal Intensive Care, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, Italy

Background: Sickle cell disease (SCD) is the most common monogenetic disease worldwide. Although it is most prevalent in Africa, in parts of the eastern Mediterranean and Asia, as a result of migration, the prevalence is also continuously increasing in central and northern Europe. It is established that early detection and appropriate prophylactic measures prevent potentially fatal complications and many European countries have already introduced newborn screening programs for SCD. In Italy it is estimated that 6.5% of the total population is represented by carriers of hemoglobinopathies[1], nevertheless, there isn't a national newborn screening program for SCD nor a plan to establish it. Selective newborn screening programs for SCD are currently active in three regions of Italy, and a pilot universal newborn was terminated due to lack of funding[2]; the benefit of universal newborn screening is still not clear n the Italian context. Since May 2016 a pilot program of universal newborn screening for SCD is active at the birth center of the Department of Women and Child- Health in Padova, which has about 3,500 births a year. In September 2016 the screening program was extended to San Gerardo Hospital in Monza, also located in Northern Italy, with centralization in Padova for samples analyses
Aims: To study the feasibility and efficacy of a universal newborn screening for SCD and to evaluate SCD epidemiology in the areas of Padova and Monza. To identify S gene carriers and affected newborns for a timely taking in charge and to provide genetic counseling for the family. To reduce morbidity and management costs of children with SCD
Methods: Guthrie cards collected after parents' informed consent, from an unselected cohort of newborns, are analyzed by HPLC (Variant Newborn Screening-NBS-BioRad). The abnormal hemoglobin fractions identified by HPLC are confirmed by molecular analysis of the β-globin gene (HBB) by PCR and sequencing of the DNA extracted from the dried blood spot. Genetic counselling is offered to the families of infants carriers of the S gene, after notification of the result; families of all infants with SCD are contacted within two months for enrollment in comprehensive care.
Results: Over a period of nine months and five months 1364 and dried blood spots were collected in Padova and Monza respectively. Two families in Padova and 19 in Monza refused the test. The ethnic origin of newborns was similar in the two sites: 64.08% were children of Italian couples, 8.21% of mixed couples and 27.71% of foreign couples in Padova. And 69.45% were of Italian couples, 9.29% of mixed couples and 21.26% of foreign couples in Monza. None of the collected samples has been excluded from the analysis. The main results are summarized in Table1.

Table 1. Summary of screening results.

PADOVA

Number of newborns	Sex		Hemoglobin pattern						
1364	Male	Female	FA	FAS	FAC	FAE	FAD	FS	FSC
	716	648	1350	**8**	1	0	1	**1**	**1**
	52.50%	47.50%	98.97%	**0.58%**	0.07%	0	0.07%	**0,07%**	**0,07%**

MONZA

Number of newborns	Sex		Hemoglobin pattern					
1077	Male	Female	FA	FAS	FAC	FAE	FAD	FS
	555	522	1060	**1**	4	2	2	**0**
	48.47%	51.53%	98.42%	**0.092%**	0,37%	0.19%	0,19%	**0**

Summary/Conclusions: These preliminary data indicate the feasibility and effectiveness of a multicentric universal newborn screening program in Italy. The incidence of S abnormality is in agreement with the only previous Italian universal newborn screening experience conducted in a single city[2]. Moreover, the results confirm the high incidence of other hemoglobin variants such as HbC, HbD and HbE. The affected children received dedicated medical care from birth. Our preliminary data confirm and support the need for a universal newborn screening that should be extended to the whole country.

EXTENDING ACCESS TO CARE FOR CHILDREN WITH SICKLE CELL DISEASE THROUGH TELEHEALTH

J. Kanter[1,*], J. Mcelligott[1]
[1]Pediatrics, Medical University of South Carolina, Charleston, United States

Background: Sickle Cell Disease (SCD) is the most common inherited blood disorder in the United States and is highly prevalent in South Carolina. Previous work using administrative databases have shown that 25% of affected individuals live in the more rural PeeDee region and seek acute care from community hospitals. As a result, many of these patients have to travel >90 minutes for routine SCD care. Due to the difficulty in travel, many patients from this region were seen less frequently which made more time-intensive interventions difficult. Hydroxyurea, the only drug FDA-approved to modify the course of SCD, requires monthly laboratory assessments in the firstyear and every 3 months in subsequent years. Thus, in addition to concerns with medication side effects, the frequency of visits limits this option for individuals in rural areas with SCD.
Aims: The primary aim of this project was to evaluate the feasibility and acceptability of using a telehealth clinic to provide SCD care for children living in a designated rural area. The secondary aims were to improve the clinic adherence for patients living in the rural PeeDee region, decrease the burden of care and expense of travel for affected families and improve Hydroxyurea acceptance and uptake.
Methods: The Medical University of South Carolina (MUSC) Center for Telehealth agreed to sponsor the necessary equipment including the video communication system, moveable camera and tele-stethoscope. A regional partner was identified in the target area willing to host the telehealth clinic. Nurses and Advanced Practice Providers were trained in using the equipment and also trained in spleen palpation techniques which cannot be performed using the telehealth system. A local hospital was also identified where routine laboratories can be performed for children seen in the local clinic. Pediatric patients currently seen at the central academic center (MUSC) living in this region were contacted to assess their interest in coming to the telehealth clinic.
Results: The pediatric SCD telehealth clinic was initiated in November, 2014 and data reflects the first 16 months of practice. There were originally 21 patients identified from MUSC of whom 4 families declined interest in participating. Two additional children with known SCD were referred from the local pediatric group for the telehealth clinic who had been designated as "lost to follow up (LTFU)." The clinics were originally scheduled monthly however three clinics were cancelled during the first 16 months and a total of 13 clinics were conducted. There were 64 total visits scheduled of which 50 visits were completed. The overall no-show rate was 14% (range 0-34%) and six clinics had a no-show rate of 0%. The scheduling rate was 78% (range 60-100%). The primary aim was to assess the feasibility and acceptability of a telehealth clinic measured by patients' and families' adherence to scheduled appointments. Of the original cohort of 19 patients, 100% (19) have continued participating in clinic (defined as attending more than 3 clinics in the 16-month period). Prior to starting the telehealth clinic, 10 of the 19 patients had only been seen once in the previous calendar year and 5 of those patients had not been seen in >18 months. Three new patients were started on Hydroxyurea. Two additional referrals to the telehealth clinic were made during the first 13 months (young adults with SCD who had been LTFU for over 3 years). These young adults were seen once by telehealth and then referred to MUSC for the young adult clinic.
Summary/Conclusions: The pediatric SCD telehealth clinic met its primary aim and has continued monthly operations. Hydroxyurea initiation has improved and decreased travel has been welcomed by participating families. Challenges have included equipment issues, difficulties in post-clinic care coordination and assuring caregivers received discharge information. Future directions include a tele-transcranial Doppler program from children with SCD at risk for stroke and additional telehealth clinics for adults with SCD that will be utilized for both routine care as well as acute care through the state sickle cell network, (SC)[2]. This approach will both harness the resources of the state to approach SCD and will also use a technology-based approach to increase education of providers.

E1491

EMERGING NEED FOR SICKLE CELL DISEASE NEWBORN SCREENING PROGRAM IN ITALY, A EUROPEAN COUNTRY WITH INTENSE MIGRATION FLUXES

D. Venturelli[1,*], G. Russo[2], L. Sainati[3], L. De Franceschi[4], F. Fagioli[5], G.L. Forni[6], O.T.B.O. SITE-AIEOP [7]

[1]Servizio Immunotrasfusionale, Azienda Ospedaliero Universitaria Policlinico, Modena, [2]UOC Emato-oncologia Pediatrica, Azienda Policlinico Vittorio Emanuele, Catania, [3]UOC Emato-oncologia Pediatrica, Azienda Ospedaliera-Università, Padova, [4]Dipartimento di Medicina Interna, Policlinico, Verona, [5]Pediatric Oncohematology, • A.O. Città della Salute e della Scienza-Ospedale Infantile Regina Margherita, Torino, [6]Haematology-Centro Microcitemia Anemie Congenite, Ospedale Galliera Genova, [7]SITE, Genova, Italy

Background: The incidence of the Sickle Cell Disease (SCD) has increased in Europe because of the high rate of migration from areas in which carriers of the sickle cell allele account for 19-27% of the entire population. Although SCD is endemic in Southern Italy, the recent migration fluxes spread SCD all over Italy with the number of carriers at about 6.5% of the whole population. The distribution of SCD patients has dramatically changed. The large part of resident immigrants are young with an high fertility rate. Neonatal screening combined with timely diagnostic testing, parental education and comprehensive care markedly reduces morbidity and mortality of SCD. Up to now, a national newborn screening program for SCD is not active in Italy and only few pilot studies have been carried out (Ballardini E *et al.* Blood Transfus. 2013 Apr: 11(2): 245-9.;Venturelli D et al.. Blood Transfusion 2014; 12: 346-51.; Rolla R *et al.* Clin Lab 2014; 60 (12): 2089-93).
Aims: To provide recommendation for newborn screening program for SCD in Italy.
Methods: A panel of experts was identified by Italian Society of Thalassemia and Hemoglobinopaties (SITE) and Italian OncoHematology Pediatric Association (AIEOP).The panel has rigorously revised the literature (from 1990 to 2016), the exhisting recommandations/guidelines of other countries where newborn screen for SCD already exhists. The GRADE system (Grading of Recommendations Assessment, Development and Evaluation) was used to score levels and grades of evidence. The working group produced the draft guideline, and the final version has been revised by external (international) reviewers and the national patients association (UNITED).
Results: The recommendations were divided into in five sections according to the newborn screening program as well as: 1) testing of newborns and specific screening methods, 2) evaluation of screening results for a definitive diagnosis, 3) enrollment of affected newborns in comprehensive care programs, 4) evaluations of the efficacy of follow-up and interventions, and assessment of the benefit to the patient, family, and society. The on line access for recommendations will be available for clinicians and healthcare providers.
Summary/Conclusions: The recommendations for SCD newborn screening program will be an important tool (i) in discussion of strategical new born screening panel at national level; (ii) to early identify patients to be treated in comprehensive SCD centers and (iii) to produce epidemiological data required for future design of SCD map in Europe.

E1492

GENETIC HEMOLYTIC MARKER IN SICKLE CELL ANAEMIA

P. Pereira Nascimento[1,*], L. Souza Torres[1], D. Grunig Humberto da Silva [1], J. Viviane Okumura[1], É. Belini Junior[2], C. Lopes de Castro Lobo[3], C. Regina Bonini-Domingos[1]
[1]Departamento de Biologia, Instituto de Biociências, Letras e Ciências Exatas - Ibilce/UNESP - São José do Rio Preto, São José do Rio Preto, [2]Medicina - UFMS/CPTL, Universidade Federal de Mato Grosso do Sul, Três Lagoas, [3]HEMORIO, Instituto de Hematologia Arthur de Siqueira Cavalcanti, Rio de Janeiro, Brazil

Background: The heterogeneity and complexity of the phenotypic profile among individuals with sickle cell anemia (SCA) its one of the principals focus of current research. The SCA, a homozygous condition for Hb S, is a hereditary haemolytic anemia wich severe clinical consequences. The intravascular hemolysis is a chronic clinical subphenotype and has been associated as an independent risk factor related to complications such as pulmonary hypertension, leg ulcer and more recently with progress of vasculopathies. Researches has already shown that the heterogeneity of the hemolytic profile can be due to the presence of different beta S-globin gene cluster haplotypes among the individuals, which suggests the participation of genetic factors in the characterization of this subphenotype. Thus, search for genetic variants has been a promising strategy to assist in the individualization of treatments, and favoring clinical evolution. Recent studies showned that the presence of at least one rs7203560 SNP allele (G) of the NPRL3 gene plays a protective role at hemolysis in individuals with SCA, suggesting this variant as a genetic marker of hemolysis.
Aims: Our objective were to evaluate the association between different genotypes of the SNP rs7203560 and the intravascular hemolysis in patients with SCA.
Methods: We evalueted 76 Brazilian people with SCA, all with a Bantu / Bantu haplotype profile, and in a steady state. The patients were divided into two groups: wich with use or without use of hydroxycarbamide (HC): 22 individuals using (Bantu / Bantu + HC) and 54 without (Bantu / Bantu - HC), respectively. The plasmatic hemoglobin (cell-free hemoglobin - Hb) was measured by enzyme-linked immunosorbent assay (ELISA) to evaluated intravascular hemolysis. The association between categorical variables (with or without use of HC and diferents SNP genotypes) and cell-free Hb levels was performed by univariate covariance analysis (GLM), followed by Fisher's Post Hoc, considering the gender and age covariables. Statistic software was used and assumed p <0.05 as significant
Results: Evaluating the recessive model (GG / GT *versus* TT), we found a significant difference between the different genotypic patterns (p=0.026), and not for HC treatment. Therefore, we performed an analysis to evaluate the participation of SNP in the variation of cell- free Hb levels and hemolysis markers commonly used as hemolysis parameters (relative reticulocytes, the enzymes lactate dehydrogenase and aspartate aminotransferase and unconjugated billirubin), and we found that the individuals genotypic profile was responsible for 50.7% of this variation (Wilk's λ: 0.507; F: 4.08; p-value <0.001), suggesting that the SNP may play a role in characterizing the hemolytic profile of our patients with SCA.
Summary/Conclusions: The SNP here studied is located in the intronic region of the NPRL3 gene, where the main regulatory elements of the alpha globin gene cluster (HS-48, HS-30 and HS-33) are also found. Studies have already suggested that the protective effect of the G allele of the SNP on the hemolytic profile may be probably related to the role of this genetic variant in the expression of the alpha globin genes. Its promissing that aditional analyzes in other ethnic groups and models of hemolytic anemias, such as those of an acquired character are realized. This is one of our next step in the attempt to suggest this variant as a genetic marker capable of assisting in the characterization of the hemolytic and prognostic profile of people with SCA.

E1493

ASSESSMENT OF INTERNATIONAL DAY HOSPITALS/INFUSION UNITS FOR THE EVALUATION AND TREATMENT OF SICKLE CELL DISEASE

L. De Castro[1,*], J. Jonassaint[2]
[1]Internal Medicine, University of Pittsburgh Medical Center, [2]Internal Medicine, UPMC, Pittsburgh, United States

Background: A Sickle Cell Disease (SCD) Day Hospital is defined as a "dedicated facility for the treatment of SCD uncomplicated painful crises, operating on principle-based pain management". SCD Day Hospital/Infusion Units (SCD-DH/IU) play a positive role in improving pain management, preventing emergency room visits, hospitalizations, and readmissions. No study to date has systematically surveyed the availability, organization, diagnostic tools/therapy provided, and number of SCD patients treated at these facilities as well as compared these facilities' practices based on location
Aims: To evaluated and compare availability and characteristics of key SCD-DH/IU components with the overarching goal of enhancing and standardizing across facilities, guidelines and standard of care and help supporting the development of alike outpatient-care units at other health care institutions and countries.
Methods: A Web-based survey was developed and link to the survey sent via email in September 2016 and January 2017, to 120 health care providers (80 in the USA and 40 in other countries) identified via the Global Sickle Cell Disease Network as caring for individuals with SCD. Responses were collected between September 4 and February 10, 2017. Data was analyzed by descriptive statistics and T tests using Graphpad.
Results: Fifty seven surveys were completed (41% response rate) from 51 unique institutions. Responders from the USA sites, 27 (53%) were, mostly, from long-standing sickle cell institutions in the East, West, and South. Non USA sites, 15 (29%) included Canada, Oman, France, Kuwait, and England. Location of nine sites (18%) was not available. Data from only 42 sites showed: 34 (80%) sites reported having a SCD-DH/IU facility. Thirty-one (73%) sites care for 200 or more individuals with SCD, including 17(40%) caring for more than 400 SCD patients. Self-standing units accounted for 30% of SCD-DH/IU, while most (63%) were part of a multi-specialty unit. Only three site operated 24 hours/day, 7 days/week, while 50% of the sites functioned Monday-Friday, 8am-5pm. Half of the SCD-DH/IU sites treat 1-3 SCD patients, 34% treat 4-6 and only 8% treat more than 10 daily. Treatments a vailable at SCD-DH/IU varied among sites. All performed blood tests, but not all were able to provide IV hydration, IV pain management, and blood transfusions. SCD-DH/IU data such as utilization, therapy outcomes, and admissions/readmissions were tracked by 74% of the sites. Only 44% have standard post-discharge/follow-up procedures, ¾ of those were Non-USA sites. Most (69%) sites provide individualized care plans for pain management. Only 29% use Patient Controlled Analgesia (PCA). Most 85% allowed direct hospital admissiol for patients initially evaluated in the SCD-DH/IU. Seven (19%) sites do not have a dedicated provider (MD/PA/NP) available to triage SCD patients presenting to the SCD-DH/IU. Twelve SCD-DH/IU sites have both a SW and a psychologist on site to address patients' psychosocial issues, 21 sites have only a SW, one has only a psychologist, and six neither available. When presented with three different clinical scenarios, sites significantly differed in services availability. Data analyzed based on geographical location, *i.e.* USA *vs* Non-USA showed similar results independently of location; trends for higher protocols use and data tracking in the USA sites; but higher availability of triage medical staff in Non-USA sites. Notably, 50% of Non USA sites, only treated patients 18 years and younger, p=.003.

Table 1.

* Location of nine (9) sites not available, thus not included in this analysis
‡ 3/5 Non USA sites that use individualized pain plans also use PCAs
§ 5/17 USA sites that use individualized pain plans also use PCAs

Summary/Conclusions: This is the first study highlighting key healthcare practice data for the small but significant number of SCD Day Hospital/Infusion Units around the globe. Our data suggest that among institutions with SCD-DH/IU there is no consensus regarding clinical practice or data collection. We conclude that there is a significant need to further evaluate SCD DH/IU patient-based value, and to develop operational standards / benchmarks to ensure dissemination, adaptability, and sustainability of these alternative care models

E1494

REDUCED SERUM HAEMOPEXIN LEVELS IN HAEMOGLOBIN SC DISEASE OCCUR INDEPENDENTLY FROM THE DEGREE OF HAEMOLYSIS

F. Vendrame[1,*], L. Marani[1], S. Saad[1], F. Costa[1], K. Fertrin[1]
[1]Hematology and Hemotherapy Center, Unicamp, Campinas, Brazil

Background: In intravascular haemolysis, saturation of haptoglobin leads to haemoglobin oxidation and the release of free haem, whose main scavenger is haemopexin. In sickle cell mice, excess free haem has been shown to cause vaso-occlusion that can be reversed by haemopexin, implicating that knowledge on how haemolysis changes haemopexin production may influence the applicability of clinical use of haemopexin for sickle cell disease and other haemolytic states. Recent studies have reported reduced haemopexin levels in children with sickle cell disease (Santiago et al., 2016) and adults with beta thalassemia (Vinchi et al., 2016) in association with elevated haem levels, thus suggesting haemopexin decreases due to chronic haemolysis. No data are available in adults with milder sickling disorder haemoglobin SC (HbSC) disease.
Aims: In this study, we examined haemolytic markers, haem, and haemopexin levels in samples from HbSC patients with varying degrees of haemolysis in comparison with healthy subjects with no abnormal haemoglobins (HbAA group).
Methods: Forty HbSC patients (age range 25-68 years, 15 men) and forty HbAA controls (age range 18-66 years, 28 men) participated in this study. Exclusion criteria were pregnancy, other cause of haemolysis, history of blood transfusion or sickle cell pain crisis in the past 3 months. Venous blood samples were collected for complete blood counts (Advia 2120, Siemens) and measurement of lactate dehydrogenase (LDH), bilirubin (Roche Hitachi), haem (Bioassay Systems), and haemopexin (Abcam) levels. Statistical analysis was performed with GraphPad Prism v.5 and data are expressed as mean±standard deviation.
Results: As expected, serum LDH, total and indirect bilirubin, and reticulocyte counts were increased in HbSC patients (*P*=0.0001). Despite this, no significant difference in total circulating haem was found between HbSC and HbAA (39±2.6 *vs* 35±1.8 μM, respectively, *P*=0.30), but haemopexin was surprisingly elevated in HbSC patients when compared to HbAA (15,080±488 *vs* 8,407±684 ng/mL, *P*= 0.0001), contrary to what has been reported in other haemolytic diseases. Haemoglobin (Hb) was higher in the HbAA group when compared to the HbSC group (15±0.2 *vs* 12±0.3 g/dL), and considering World Health Organization definitions of anaemia for men (Hb below 13g/dL) and women (Hb below 12g/dL), 20 (50%) patients in our HbSC cohort were not anaemic, thus fulfilling criteria for compensated haemolysis. HbSC patients with compensated haemolysis were not significantly different from their anaemic counterparts, with similar reticulocyte counts, LDH, bilirubin, haemopexin (9,836±948 *vs* 7,739±813 ng/dL, *P*= 0.10), and total haem levels (33.92±2.4 *vs* 37.55±2.9 μM, *P*=0.30). We also found an unexpected negative correlation between haemoglobin and haemopexin, r=-0.42 (Pearson), *P*=0.007).
Summary/Conclusions: Despite the putative importance of reduced haemopexin in the pathophysiology of sickle cell disease, HbSC patients do not always present with haemopexin deficiency, regardless of the intensity of the haemolytic state, and possibly to due to a lesser importance of intravascular haemolysis. Our data support that non-anaemic HbSC patients may be equally affected by haemolysis, but intravascular haemolysis does not predominantly regulate haemopexin production. We suggest that excessive free haem and low haemopexin probably represent a lesser contribution to the pathophysiology of complications found in this subgroup of sickling disorders.

E1495

ASSOCIATION OF TOLL-LIKE RECEPTOR 2 GENE POLYMORPHISM WITH THE INCIDENCE OF BACTERIAL INFECTIONS IN SICKLE CELL DISEASE

K. Tozatto-Maio[1,2,3,*], R. Girot[4], C. Mariaselvam[5,6], M. Bennabi[5,6], A. Ruggeri[1,2], B. Cappelli[1,2], R. Krishnamoorty[5], B. Pinto Simões[3], I. Diagne[7], E. ,Gluckman[1], R. Tamouza[56]
[1]Eurocord, Université Paris 7, Paris, France, [2]Monacord, International Observatory on Sickle Cell Disease, Centre Scientifique de Monaco, Monaco, Monaco, [3]Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil, [4]Hôpital Tenon, [5]Inserm U1160, Université Paris 7, Paris, [6]Hôpital Henri Mondor, Créteil, France, [7]Pediatrics Unit, Centre Hospitalier National d'Enfants Albert Royer, Dakar, Senegal

Background: Despite antimicrobial prophylaxis and immunization, bacterial infection remains a leading cause of morbidity and mortality in sickle cell disease (SCD) patients. Functional hyposplenia/asplenia partially explains their susceptibility, since even young SCD children with functional spleen are at raised infectious risk. Toll-like receptors (TLR), that recognize pathogen molecular patterns, are at the forefront of immune protection. The interaction between TLR and infectious diseases in SCD patients has never been explored.
Aims: To evaluate if functional polymorphisms in TLR confer susceptibility/resistance to infections in SCD.
Methods: 160 SCD patients followed either in France (n=104) or Senegal (n=56) with recorded history of infections were tested for SNPs in TLR-1, TLR-2, TLR-4, TLR-6 and TLR-10 by TaqMan 5'-nuclease assay for their association with infectious history. Comparisons between groups were evaluated by x^2 or Fisher exact T-test with Bonferroni corrections of P-value (Pc); associations were measured by odds ratio (OR).
Results: 76 patients were positive for at least one bacterial infectious episode (IP) and 84 had no infection (NIP). Eleven IP had more than one episode of infection. Median age was 25 years (range 4-49) for IP and 23 years (range 3-52) for NIP with no distribution bias in gender (p=0.24). All patients had vaccinations against *Streptococcus pneumoniae* and *Haemophilus influenza B,* and patients under 10 years had received penicillin prophylaxis. Etiological agent was identified in 58 cases with encapsulated bacteria (EB) occurring in 35; the most common agents consisted of *Mycobacterium tuberculosis*, *Streptococcus pneumoniae*, *Salmonella spp*, *Escherichia coli* and *Klebsiella pneumoniae*. Sites of infection included respiratory tract (n=24), bone and joints (n=21), blood stream (n=17), urinary tract (n=11), central nervous system (n=8) and abdominal (n=5). TLR-2 *rs*4696480 TA genotype was less represented in IP than in NIP [45% *vs* 98%, OR=0.02, 95%CI=0.01-0.09, Pc<0.003] and in particular TLR-2 *rs*4696480 TA genotype was significantly less frequent in the group of patients infected by EB as compared to NIP+IP with other known etiological agents [51% *vs* 85%, OR=0.19, 95%CI=0.08-0.44, Pc<0.003]. Other TLR SNPs, genotype and haplotype showed no significant difference between groups.
Summary/Conclusions: *rs*4696480 TA genotype apparently confers protection against infections especially for EB. Given the previously demonstrated association of AA genotype with exacerbated expression of inflammatory cytokines as well as association of T allele with lower expression of cytokines it is tempting to postulate that TA genotype can be considered as a compromise between deleterious effects of over inflammatory response (TLR-2 AA genotype) and under response (TLR-2 TT genotype) to infectious agents. Such balanced selection effect is probably reflected by the observed deviation from HWE.

Stem cell transplantation - Clinical

E1496

HIGH PROGNOSTIC VALUE OF PRE-SCT MOLECULAR MINIMAL RESIDUAL DISEASE ASSESSMENT BY WT1 GENE EXPRESSION IN AML TRANSPLANTED IN CYTOLOGIC COMPLETE REMISSION

A. Candoni[1,*], M.E. Zannier[1], E. Bertoli[1], F. De Marchi[1], E. Simeone[1], C. Fili'[1], D. Lazzarotto[1], G. Ventura[1], E. Toffoletti[1], N. Rabassi[1], C. D'Odorico[1], C. Comuzzi[1], R. Fanin[1]
[1]Division of Hematology and SCT, University Hospital, Udine, Udine, Italy

Aims: We analyzed the outcome of allogeneic Stem Cell Transplantation (allo-SCT) in AML patients according to molecular Minimal Residual Disease (MRD) at the pre transplantation (pre-SCT) workup, assessed by the quantitative expression evaluation of the panleukemic marker Wilms' tumor gene (WT1), according to LeukemiaNET validated method.
Methods: 122 consecutive AML patients received allo-SCT while in cytologic Complete Remission (cCR), between 2005 and 2016, at our Center. The median age at SCT was 53 years (18-70). The quantitative analysis of the WT1 gene expression (bone marrow samples) was available in 100% cases, both at diagnosis (100% overexpressing WT1 with a mean of 8607±8187 copies/10^4 Abelson) and before allo-SCT (81/122-66% MRD-WT1-negative and 41/122-44% MRD-WT1 positive cases at the pre-SCT workup). We evaluated post-SCT Overall Survival (OS), Disease Free Survival (DFS) and Relapse Rate, according to MRD-WT1 pre-SCT status.
Results: Both post-allo-SCT OS and DFS were significantly better in patients who were MRD-WT1 negative (WT1<250 copies) at the time of SCT compared with those who were MRD-WT1 positive (WT1>250 copies), with a median OS and DFS not reached in the MRD-WT1 negative group and 9 and 8 months, respectively, in the MRD-WT1 positive group (OS log-rank p<0.0001; hazard ratio [HR]=3.9, 95% confidence interval [95% CI]=2.0-7.38; DFS log-rank p<0.0001; HR=3.73, 95% CI=2.0-6.72). The relapse rate after allo-SCT was 15% (12/81) in pre-SCT MRD-WT1 negative cases and 44% (18/41) in MRD-WT1 positive cases (p=0.00073). At univariate analysis, MRD-WT1 negativity before allo-SCT and grade <2 acute GVHD were significant prognostic factors for improved OS and DFS. However, at multivariate analysis, MRD-WT1 negativity before allo-SCT was the only independent prognostic factors for improved OS and DFS.
Summary/Conclusions: These data show that pre-allo-SCT molecular MRD evaluation through WT1 expression is a powerful predictor of post-SCT outcome (OS, DFS, relapse rate). Patients with both cCR and a MRD-WT1 negativity before allo-SCT have a very good outcome with a very low relapse rate and better survival. The pre-SCT MRD-WT1 stratification in AML is a valuable tool to identify patients, transplanted in cCR, who are at high risk of relapse and who could be considered for conditioning regimen intensification and/or for post-SCT preemptive strategies (donor lymphocyte infusion, tapering of immunosuppression, azacitidine or new target drugs).

E1497

GOOD IMMUNOLOGICAL RECONSTITUTION IN ADULTS WITH ACUTE LEUKEMIA AFTER ALFA-BETA TCR/CD19+ DEPLETED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT)

L. Prezioso[1,*], S. Bonomini[1], C. Schifano[1], A. Monti[1], I. Manfra[1], A. Spolzino[1], G. Sammarelli[1], L. Craviotto[1], M. Sassi[2], M. Soli[2], F. Aversa[1]
[1]Hematology and BMT Unit, [2]Immunohematology and Transfusion Unit, Parma, Italy

Background: Haplo-HSCT based on the infusion of high numbers of T cell depleted (TCD) hematopoietic progenitor cells and no post-transplant immunosuppression controls both graft rejection and GvHD in patients with acute leukemia. One major remaining issue is the delay in the post-transplant immunological reconstitution because of the minimal residual T lymphocytes in the graft and *in vivo* ATG-linked T cell depletion. Current studies are focussing on rebuilding posttransplant immunity to improve clinical outcomes separating GvHD from favourable donor immune responses. Selective elimination of αβ+ T cells retains in the graft NK, dendritic cells, monocytes and γδT lymphocytes. Under this approach, a rapid immunological reconstitution and very promising outcome have been reported in pediatric patients.
Aims: With the aims of confirming these results in adults, we tested this approach in adults with acute leukemia.
Methods: Thirty-two patients, median age 51 years (range 19-74), with AML (n=27) or ALL (n=5) entered to study. Twenty were in CR (12 CR1; 8 CR≥2), 12 in advanced-stage disease at transplant. Conditioning consisted of ATG 1,5mg/kg from day -13 to -10, Treosulfan 12 gr/sqm from -9 to –7, Fludarabine 30mg/sqm from -6 to -2 and Thiotepa 5mg/Kg on days -5 and -4. PBPCs from haplo-donor (3 mothers, 9 siblings, 13 sons/daughters and 7 cousins) underwent αβTCR/CD19+ depletion by CliniMACS. No post-transplantation immunosuppression was given. Ganciclovir was given over the conditioning regimen in the 22 patients who were CMV seropositive; L-AmB was used as anti-mold active prophylaxis over the neutropenic phase
Results: Grafts contained a median of $11x10^6$/kg (range 5-19) CD34+ cells, $4.3x10^6$ $CD3^+$Tcells/kg (range 1-36), $4.9x10^4$/kg (range 0.4-62) $\alpha\beta^+$T cells, $4x10^6\gamma\delta^+$Tcells/kg(range 1-34), $5x10^4$B cells/kg (range 1.5-32) and $22x10^6CD56^+$NKcells/kg (range 5-91). All patient achieved a full donor sustained engraftment. Median time to reach 500 neutrophils and 20,000 platelets was 13 (range 10-18) and 11 days (range 6-30), respectively. Two patients developed and died from severe acute GVHD. One of them had received the highest dose of αβ+T cells ($3.7x10^5$/kg) and the second one affected by 6GPDH deficiency experienced a late onset hepatic GVHD. Eight patients had skin limited grade II aGVHD that required short course steroids. Only two patients have so far developed mild cGvHD that recovered completely after steroid and cyclosporin treatment. Tending to confirm our working hypothesis, there was a rapid, sustained increase in peripheral blood T-cell subpopulations (Fig. 1). Naïve and memory T-cell subsets increased significantly over the first year after transplantation. B-cell reconstitution was rapid and sustained and immunoglobulin serum levels normalized within 3 months. CMV reactivation occurred in 9 of the 30 patients who were at risk (only 3 had 2 or more CMV reactivations). One with unfavorable serology (donor negative into recipient positive) developed and died of CMV disease 8 months after transplant. Relapse was the main cause of failure (8/12 in relapse, 3/20 in CR). NRM was 15% (4/12 in relapse, 4/20 in CR), 13 patients survive at a median follow-up of 29 months (range 5-53).

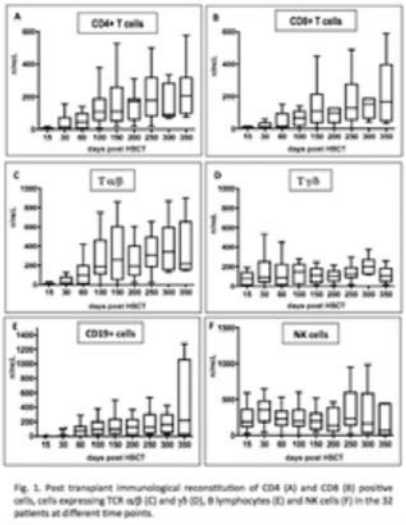

Fig. 1. Post transplant immunological reconstitution of CD4 (A) and CD8 (B) positive cells, cells expressing TCR αβ (C) and γδ (D), B lymphocytes (E) and NK cells (F) in the 32 patients at different time points.

Figure 1.

Summary/Conclusions: The infusion of αβ/CD19-depleted grafts confirmed a fast immunological reconstitution also in adults. Relapse is still a major concern in patients already in relapse at transplantation.

E1498

UNMANIPULATED HAPLOIDENTICAL TRANSPLANTATION CONDITIONING WITH BUSULFAN, CYCLOPHOSPHAMIDE AND ANTI-THYMOGLOBULIN FOR ADULT SEVERE APLASTIC ANEMIA: GOOD OUTCOME AND PROGNOSIS ANALYSIS

Z. Xu[1], L. Xu[1,*], F. Wang[1], X. Mo[1], T. Han[1], W. Han[1], Y. Chen[1], Y. Zhang[1], J. Wang[1], Y. Wang[1], C. Yan[1], Y. Sun[1], F. Tang[1], X. Zhang[1], X. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China, Beijing, China

Background: Severe aplastic anemia (SAA) is a life-threatening disorder for which allogeneic hematopoietic stem cell transplantation (HSCT) is the available curative approach. Recently, more and more studies have focused on the feasibility of haplo-identical transplantation in SAA patients because of donor availability.
Aims: To evaluate the outcomes and prognosis of haploidentical hematopoietic stem cell transplantation (HSCT) in adult patients with acquired severe aplastic anemia (SAA), we conducted a retrospective analysis.
Methods: A total of 49 SAA adults received haplo-identical transplantation without *in vitro* T-cell depletion between May 2011 and December 2016. Patients were administered busulfan (BU), cyclophosphamide (CY) and anti-thymoglobulin (ATG) as conditioning regimens and then bone marrow plus peripheral blood transplantation.
Results: The patients' median age was 25 years (ranging from 18 to 45). All of 47 cases surviving for more than 28 days achieved donor myeloid engraftment. The median time for myeloid engraftment was 13 (range, 10-21) days and for platelet was 17.5 (range, 7-101) days with the cumulative incidence of 93.88±0.17%. The cumulative incidence of grade II-IV and III-IV acute graft-versus-host disease (aGVHD) were 20.89±0.35% and 4.17±0.08%, respec-

tively. For patients who survived more than 100 days, the incidence of chronic graft-versus-host disease (cGVHD) were 14.94±0.40% and 27.40±0.77%, and that of extensive cGVHD were 2.57±0.07% and 7.18±0.27% at 1 year and 3 year. With a median follow up of 20.1 (2.1-70.1) months for alive patients, 3-year estimated overall survival (OS) and failure-free survival (FFS) were both 82.5±5.7%. Multivariate analysis showed hematopoietic cell transplantation-specific comorbidity index (HCT-CI) score of ≥3 was significantly associated a worse 3-year survival outcome (86.0% *vs* 50.0%, *P*=0.035, Hazard ratio [95% Confidence interval]: 6.266 [1.139-34.463]).
Summary/Conclusions: Haplo-identical transplantation without *in vitro* T-cell depletion conditioning including BU/CY+ATG is a feasible strategy for adult SAA patients, with successful engraftment, acceptable GVHD, and inspiring survival outcomes. HCT-CI might be an outcome predictor in these patients.

E1499

PLERIXAFOR EFFICIENTLY AND SAFELY MOBILIZES PERIPHERAL BLOOD STEM CELLS: HOVON-107 RESULTS IN HLA-IDENTICAL SIBLING DONORS AND TRANSPLANTED RECIPIENTS

G. De Greef[1,*], B. van der Holt[1], E. Braakman[1], J. Janssen[2], E. Petersen[3], V. Vucinic[4], N. Thuss[1], M. Grootes[1], J. Cornelissen[1]
[1]Hematology, Erasmus Cancer Institute Rotterdam, Rotterdam, [2]Hematology, Vu University Hospital, Amsterdam, [3]Hematology, UMCU, Utrecht, Netherlands, [4]Hematology, University of Leipzig, Leipzig, Germany

Background: Plerixafor (PFX) is a reversible inhibitor of stem cell-stroma cell interactions, by interrupting SDF-1 binding to CXCR4. A single subcutaneous (sc) injection results in direct release of hematopoietic stem and progenitor cells (HSPC) with limited side effects and therefore could be of advantage for allogeneic stem cell donors.
Aims: We set out to address the feasibility of sc PFX in family donors and their recipients. Feasibility was defined by the percentage of HLA-matched sibling donors in whom at least 2x 10^6/kg CD34+ cells/kg recipient weight could be harvested after 1 or 2 gifts of PFX (320µg/kg).
Methods: Currently, data of 23 donors and 23 transplanted patients are available, All donors (16 male; 7 female, median age: 47, range: 24-60) received PFX sc 9-11 hours before stem cell collection. The median age in patients was 50 (21-64), diagnoses included: AML/MDS RAEB (n-9), ALL(n-3), MM (n=4), Hodgkin/NHL (n=3), CLL (n=2), other (n=2).Transplant conditioning regimen was non-myeloablative in 17 patients and myeloablative in 6. Grafts obtained after the first gift PFX were analyzed for the total number of CD34+ cells, CD34 subsets: CD34+/CD45RA-/CD90+ and 90- cells, T-cells and distinct CD4+ T cell subsets including regulatory T cells (Treg), Th1, Th2, and Th17 cells. Median cell numbers assessed in 10 G-CSF-mobilized grafts were used as controls.
Results: Criteria for feasibility were met as in 22 out of 23 donors ≥2x 10^6kg CD34+ cells were collected. PFX was administered twice in 10 donors. Side effects CTC grade 2 occurred in 39% of donors and included gastrointestinal (17%), headache or tingling (17%), fatigue/myalgia (17%). CTC grade 3 fatigue was observed in 1 donor; in 2 donors grade 3 clotting occurred occurred during the leukapheresis procedure. All side effects resolved. The median number of CD34+ cells in the graft was 189 x 106 (range:106-548) after PFX *versus* 438 x 106 (range:360-840) with G-CSF. Within the CD34+ cells, 31% CD34+/45-/90+ cells were present after PFX *vs* 14% after G-CSF. With PFX the median number of CD3+ cells in the graft was 22.4 (11-57) x10^9 *versus* 12.8 (7.6-21) x10^9 after G-CSF. CD4/CD8 ratios were similar. The percentages of T-reg within the CD4+ cells were 6.3% (2.7-10.4) after PFX and 5.8% (2.6-10.9) after G-CSF. The Th1 cells within the PFX grafts were 24.2% (3-40.7) *vs* 16.6% (2.5-27.5) with G-CSF. The Th2 and Th17 cells after PFX and G-CSF were, respectively, 2.5% (0.4-7.5) *versus* 2.3% (0.5-4.4) and 1.3% (0.2-25.9) *versus* 1.4% (0.2-5). The unmanipulated grafts were infused according to local protocol and contained a median of 3.5x 106/kg CD34+ cells (range:1.9-6.5). All patients engrafted with prompt recovery of granulocytes >0.5x 10^9L at a median of 19 days (0-27) and platelet recovery >50 x 10^9L at day 13 (0-23). Acute graft *versus* host disease (GVHD) grade 1-4 was observed in 6 out of 23 patients, including 2 with grade 3 and no grade 4. Chronic extensive GVHD was observed in 9 patients.
Summary/Conclusions: Stem cell mobilization by sc PFX is feasible in HLA identical sibling donors with limited side effects and results in sufficient numbers of CD34+ cells for transplantation. While absolute numbers of CD34+ cells were higher after G-CSF mobilization, the subset of phenotypic stem cells was similar after both types of mobilization. No graft failures were observed and all 23 patients showed prompt recovery of neutrophils and platelets. So far, despite the infusion of higher numbers of T-cells, no increase of GVHD was apparent.

A FEASIBILITY STUDY OF THE FULL OUTPATIENT CONDUCT OF HEMATOPOIETIC TRANSPLANTS IN PERSONS WITH MULTIPLE SCLEROSIS EMPLOYING AUTOLOGOUS NON-CRYOPRESERVED PERIPHERAL BLOOD STEM CELLS

G.J. Ruiz Argüelles[1,*], A. Leon Peña[1], M. Leon Gonzalez[1], A.K. Nuñez Cortés[1], J.C. Olivares Gazca[1], J. Vargas Espinosa[1], E. Medina Ceballos[1], Y. Cantero Fortiz[1], J.A. Arizaga Berber[1], M.S. Torres Priego[1], A. Ruiz Arguelles[1], M. Ruiz Arguelles[1], R. Ruiz Delgado[1], G. Ruiz Reyes[1], M. Priesca Marin[1], G. Ruiz Delgado[1]
[1]Hematologia, Centro de Hematologia y Medicina Interna, Puebla, Mexico

Background: With the goal of immune system reset, autologous hematopoietic stem cell transplantations have been done in patients with multiple sclerosis (MS).
Aims: With the goal of immune system reset, autologous hematopoietic stem cell transplantations have been done in patients with multiple sclerosis (MS).
Methods: 131 consecutive patients with MS were autografted in a single center using non-frozen peripheral blood stem cells, on an outpatient basis and conditioning with cyclophosphamide (Cy) and rituximab. The protocol was registered in ClinicalTrials.gov identifier NCT02674217. The PBSC mobilization schedule was done with Cy and Filgrastim (G-CSF). Intravenous Cy (50mg/Kg) was delivered on days -11 and -10. Sucutaneous G-CSF (10ug/Kg/BID) was delivered on days -9 to -1. The apheresis procedure was performed on day -2. The apheresis objective was to reach at least 1 x 106 viable CD34+ cells/Kg. As outpatients and after collecting the PBSC, intravenous Cy (50mg/kg) was delivered over a 120 minute period, on days -2 and -1 followed by MESNA (1000mg/m^2 over a 180 minute period). After the intravenous Cy, oral ondasetron, oral cotrimoxazole, oral fluconazole and oral acyclovir were used in all patients until granulocytes were greater than 0.5x109/L. After the recovery of the granulocytes, patients were given rituximab (375mg/m^2 over a 3 h period) and subsequently rituximab (100mg) every two months over a 12-month period. The cumulative dose of Cy is 200mg/Kg.
Results: 80 females and 51 males were included; median age was 47 years. 28 have PPMS, 42 RRMS, and 61 SPMS. All procedures were started on an outpatient basis and two persons were admitted to the hospital during the procedure. In order to obtain at least 1x106/Kg viable CD34 cells, one to four apheresis were performed (median 1). Total number of viable CD34+ cells infused ranged between 1 and 9.6x106/Kg (median 2.2). Patients recovered above 0.5 x109/L absolute granulocytes on median day 9 (range 6 to 12). Two individuals needed red blood cells but none needed platelet transfusions. There were no transplant related deaths and the 125 month overall survival of the patients is 100%. In a subset of 78 persons followed for 3 months or more the EDSS (Expended Disability Status Scale) was assessed three months after the graft and means diminished from 5.2 to 4.9. The EDSS score improved in 33 patients (42.3%), remained stable in 29 (37.17%) and worsened in 16 (20.51%). Best results of EDSS were found in Relapsing Remitting (82%) and Primary Progressive (80%) type of MS compared to Secondary Progressive (71.4%).

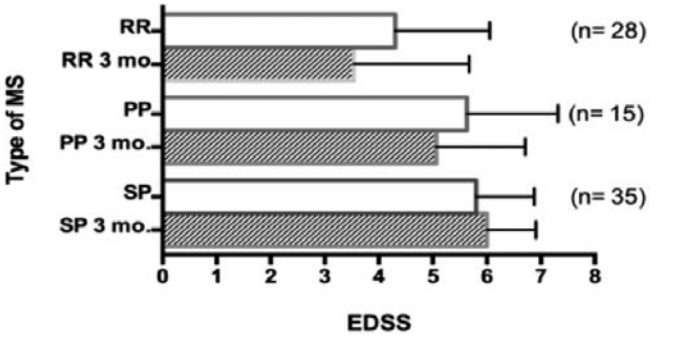

Figure 1.

Summary/Conclusions: It is possible to conduct autotrasplants for patients with MS employing non-frozen peripheral blood stem cells and outpatient conduction. Additional information is needed to assess the efficacy of these procedures in the treatment of patients with MS.

VEDOLIZUMAB IN STEROID REFRACTORY INTESTINAL GRAFT-VERSUS-HOST DISEASE

A.E. Myhre[1,*], J.D. Kristiansen[1], K.E.A. Lundin[2], L.T.N. Osnes[3], D.J. Warren[4], G.E. Tjønnfjord[1], T. Gedde-Dahl[1], Y. Fløisand[1]
[1]Hematology, [2]Gastroenterology, [3]Immunology, [4]Medical Biochemistry, Oslo University Hospital, Oslo, Norway

Background: Steroid refractory intestinal graft-versus-host-disease (GvHD) is a serious complication after allogeneic stem cell transplantation (allo-SCT), and treatment options are limited. We have previously described successful treatment of this condition with the antibody vedolizumab, targeting the homing of allogeneic T-cells to the intestinal mucosa by inhibiting the binding of T-cell integrin α4β7 to mucosal addressin MadCAM-1.
Aims: Explore outcome of all patients treated with vedolizumab in our department.
Methods: Prospective case series of 13 patients with steroid refractory gastrointestinal GvHD. Patients received 300mg of intravenous vedolizumab at weeks 0, 2 and 6, followed by infusions every 8 weeks if deemed necessary.

Patients were endoscopically evaluated at time of GvHD diagnosis and follow-up. Treatment characteristics are provided in table 1.

Results: All 13 patients experienced clinical responses, which were confirmed by endoscopies and in mucosal biopsies. 10 patients (77%) achieved a clinical response within 28 days, and half of these were complete responses. At last follow-up 10 patients (77%) had achieved sustained complete responses, 2 patients (15%) had responded partially and 1 patient (8%) suffered disease progression. 7 patients (54%) were alive after a median follow up of 35 weeks. The causes of death were transplantation related toxicity, GvHD in other target organs and infectious complications. Increased relative counts of CD25++ CD127low regulatory T-cells prior to treatment were observed in peripheral blood of 7 of 9 evaluable patients, and the relative counts decreased in all 7 patients during follow-up.

Table 1.

Table 1.

Age, median (range)	50 (18-67)
Time from allo-SCT to intestinal GvHD, median (range)	36 days (9-97)
Time from diagnosis to vedo, median (range)	14 days (6-374)
Intestinal GvHD clinical grade prior to vedo, mean (range)	2.7 (1-4)
Histological GvHD grade prior to vedo, mean (range)	2.9 (1-4)
Doses of vedo, median (range)	3 (1-21)
Observation time, median (range)	35 weeks (9-120)

Summary/Conclusions: Our results indicate that vedolizumab may effectively treat steroid refractory cases of intestinal GvHD and is well tolerated. The mechanism of action is believed to be inhibition of allo-reactive T-cells interacting with intestinal endothelial cells. It is unclear why regulatory T-cells were initially increased in our steroid refractory GvHD patients and subsequently normalized. This might initialle reflect a response to the alloreactive inflammation and subsequent redistribution to affected tissues and/or its resolution after successful treatment.

E1502

RISK FACTORS, OUTCOMES AND CHARACTERIZATION OF 'AUTOLOGOUS GRAFT *VERSUS* HOST DISEASE': THE MAYO CLINIC EXPERIENCE

T. Anagnostou[1,*], J. Paludo[1], M.M. Patnaik[1], M.R. Litzow[1], D.A. Gastineau[1], N. Duma[1], F.K. Buadi[1], L.F. Porrata[1], W.J. Hogan[1], G. Goyal[1], J.S. Lehman[1], S.K. Hashmi[1], S.S. Kenderian[1]
[1]Hematology/Medical Oncology, Mayo Clinic, Rochester, United States

Background: Graft *versus* Host Disease (GVHD) is a common complication of allogeneic stem cell transplantation (SCT) which is caused by the recognition of recipient antigens by the donor T lymphocytes. Acute GVHD remains a major cause of morbidity and mortality and half of the cases are refractory to steroids. The development of GVHD after autologous SCT (ASCT) is a poorly understood phenomenon. While some experts suggest that such an entity does not exist, some ASCT recipients develop clinical and histo-pathological changes similar to GVHD after allogeneic SCT.

Aims: In this analysis, we aimed to elucidate the factors that affect the outcomes of patients with autologous GVHD.

Methods: This is a retrospective analysis of patients that received ASCT at Mayo Clinic between January 2006 and December 2015. Autologous GVHD was defined as the development of clinical and histo-pathological findings indicative of GVHD in ASCT recipients, as determined by pathology review. Survival was estimated and compared using the Kaplan Meier and Log Rank tests. The study was approved by the institutional review board.

Results: Between 2006 and 2015, 3,891 consecutive patients underwent ASCT. Of these, 35 patients (0.9%) developed symptoms suggestive of GVHD warranting biopsies. In 19 of these 35 patients (54%), the histopathological changes were consistent with GVHD. The most common underlying disease in patients who developed GVHD was multiple myeloma (14 patients, 73.7%) and the most common conditioning regimen used was melphalan (16 patients, 84.2%). The median age at ASCT was 61.9 (range 49.2-72.6) years and the median time from disease diagnosis to ASCT was 3.1 (0.3-9.6) years. The median number of prior therapeutic regimens was 2 (range 1-7). GVHD manifested with gut involvement in all 19 patients, skin involvement in 8 patients (42.1%) and liver involvement in 2 patients (10.5%). The median time to symptom onset was 11 (range 3-80) days and the median time to GVHD diagnosis was 12 (range 2-162) days. Most patients (14, 73.7%) had grade 3 or 4 GVHD and the clinical grading correlated with the histopathologic grading in all patients. All but one patient received steroids with an average dose of 0.6-2.2mg/kg prednisone equivalents. The median time to symptom resolution was 15 (range 3-162) days and 14 patients (73.7%) achieved a complete resolution of symptoms. The median overall survival (OS) from the time of ASCT was not reached and 53% of patients were alive 3 years after ASCT. Of the 19 patients diagnosed with autologous GVHD, 5 (26.3%) died due to complications of GVHD or its treatment. Delay in initiation of steroids beyond 1 week was associated with lower response rates to treatment (30.8% *vs* 69.2%, p=0.03), longer duration of symptoms of GVHD (median 28 *vs* 4 days, p=0.02), and a trend towards worse 1-year OS (64.5% *vs* 83.3%, p=0.1). Higher steroid doses (>1mg/kg) were associated with a trend towards better complete response rates (76.9% *vs* 23.1%, p=0.5), although this difference did not reach statistical significance.

Table 1.

Table 1 – Baseline Characteristics and Outcomes

	Total (n=19)
Age at ASCT	
Median, y (range)	61.9 (49.2-72.6)
Gender, n (%)	
Male	11 (57.9)
Underlying disease, n (%)	
Multiple myeloma	2 (10.5)
Diffuse Large B-cell Lymphoma	14 (73.7)

Liver	2 (10.5)
GVHD grading, n (%)	
1	2 (10.5)
2	3 (15.8)
3	8 (42.1)
4	6 (31.6)
GVHD treatment, n (%)	
Steroids	18 (94.7)
Tacrolimus	1 (5.3)
Response to steroids, n (%)	
Yes	14 (73.8)
Time to event, Median, d (range)	
Time to GVHD symptoms onset from ASCT	11 (3-80)
Time to GVHD diagnosis from ASCT	12 (2-164)
Time to steroid initiation from symptoms onset	7 (0-47)
Time to GVHD symptoms resolution from steroid initiation	15 (3-162)
Outcomes	
OS, Median, y (95% CI)	NR (4.6-NR)
12-month OS, %	70%

Summary/Conclusions: Our findings suggest that autologous GVHD is associated with significant mortality and early initiation of treatment with steroids results in improved outcomes. Further studies into the mechanisms of the disease are warranted.

E1503

CNS DEMYELINATION AFTER HAPLO-HSCT AND ITS ASSOCIATION WITH THE IGG INTRATHECAL SYNTHESIS INDEX AND ANTI-MYELIN OLIGODENDROCYTE GLYCOPROTEIN ANTIBODY IN CEREBROSPINAL FLUID

X. Zhao[1], Q. Wang[1], J. Zhang[1], X. Zhu[1], Y. He[1], L. Xu[1], W. Han[1], H. Chen[1], Y. Chen[1], F. Wang[1], J. Wang[1], Y. Zhang[1], X. Mo[1], Y. Chen[1], Y. Wang[1], Y. Chang[1], L. Xu[1], K. Liu[1], X. Huang[1], X. Zhang[1,*]
[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Haploidentical haemopoietic stem cell transplant (haplo-HSCT) is an upfront and effective therapy for haematological patients, but it usually has many complications such as neurological complications. As one of the neurological complications following haplo-HSCT, immune-mediated demyelinating diseases of the central nervous system (CNS) seriously affect the patient quality of life. However, the incidence, risk factors and pathogenesis of CNS demyelination are not very well understood.

Aims: To analyse the incidence, risk factors, and prognosis of CNS demyelination after haplo-HSCT.

Methods: A study was conducted in 1,526 patients who underwent haplo-HSCT between January 2013 and June 2016. The definition of CNS demyelination during haplo-HSCT was confirmed by neurologic signs, MRI abnormality corresponding to the neurologic signs, abnormal CSF studies and the presence of systemic GVHD or the response to immunosuppressive therapy (Grauer O *et al. Brain*. 2010; 133(10): 2852-2865, *Chronic graft versus host disease*.

Page 243-51, 2009, *Thomas' Hematopoietic Cell Transplantation*. Page 766-75, Fifth Editon, 2016, Polman C H *et al. Ann Neurol*. 2011; 69(2): 292-302). Patients who did not meet these criteria and were determined to have CNS infection (bacterial, fungus, and viruses), neurotoxicity or malignancy relapse, based on clinical and laboratory findings, were excluded. The CSF immunoglobulin index includes BBB permeability, the IgG index, the CSF IgG intrathecal synthesis index, CSF and blood myelin basic protein, CSF and blood anti-myelin basic protein antibody, CSF and blood anti-myelin oligodendrocyte glycoprotein antibody.

Results: Thirty patients developed CNS demyelination after haplo-HSCT. The cumulative incidences of the diseases at 100 days, 1 year and 2 years post transplantation were 0.6%, 1.6% and 2.3%, respectively. The mean age at the time of presentation was 26.5 years (range, 10-52 years), and the mean time from transplant to the onset of neurologic symptoms was 216 days (range, 17-844 days). Nineteen patients received a corticosteroid pulse, five patients received immunoglobulin, and six patients received supportive treatment and an increase in immunosuppressive therapy. The symptoms improved in all patients. The mean duration from the time of improvement to deterioration was 5 days (±4). In univariate analysis, we found that BBB permeability and the CSF IgG intrathecal synthesis index were related to the occurrence of CNS demyelination ($p<0.1$). In multivariate analysis, the CSF IgG intrathecal synthesis index (OR=1.017, 95% CI: 1.003-1.031, p=0.019) and CSF myelin oligodendrocyte antibody (OR=12.059, 95% CI: 1.141-127.458, p=0.038) were independently associated with the onset of CNS demyelination. We also studied the possible pathogenesis of CNS demyelination. Immune reconstitution (the cell proportion of CD19+B cells, CD3+T cells, CD4+T cells), the count of leucocytes, lymphocytes, monocytes and platelets, as well as the level of immunoglobulins A, G and M +30 days, +60 days, and +90 days after HSCT showed no significant differences between CNS demyelination and no demyelination ($P>0.05$). The probabilities of overall survival showed no significant differences between patients with and without demyelination.

Summary/Conclusions: The CSF IgG intrathecal synthesis index and CSF anti-myelin oligodendrocyte glycoprotein antibody are independently risk factors for the onset of CNS demyelination after haplo-HSCT and have no influence on long-term survival. Immune reconstitution may not be pathogenesis of CNS demyelination.

E1504

BASELINE CREATININE CLEARANCE AND ALBUMIN ARE POWERFUL RISK FACTORS FOR ALLOGENEIC TRANSPLANTATION RELATED MORTALITY

R. Shouval[1,*], N. de Jong[2], J. Fein[1], E. Braakman[2], A. Broers[2], J. Kuipers[2], N. Shem-Tov[1], I. Danylesko[1], R. Yerushalmi[1], A. Shimoni[1], A. Nagler[1], J. Cornelissen[2]

[1]Hematology Division, Chaim Sheba Medical Center, Tel-HaShomer, Ramat-Gan, Israel, [2]Department of Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: The course following allogeneic hematopoietic stem cell transplantation (HSCT) varies between individuals. Baseline comorbidities, commonly scored by the Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), are important determinants of transplant risk. However, their prognostic utility varies and only partially accounts for transplantation-related mortality (TRM). Standard pre-HSCT laboratory carries objective physiologic information which can be used for TRM risk estimation.

Aims: Determine the value of pre-HSCT estimated creatinine clearance (CrCl), albumin, and alkaline phosphatase (Alk-p) for TRM prediction.

Methods: The study population included 1,217 patients from two European centers. Indications for transplantation and conditioning regimens were diverse. Donors were either HLA-matched sibling donors (54%), matched unrelated donors (30%), or 9/10 HLA-mismatched unrelated donors (15%).The impact of CrCl, albumin, and Alk-p on TRM was evaluated in a univariate and multivariate analysis, adjusted for age, HCT-CI, disease status, donor-recipient sex mismatch, donor type, cytomegalovirus serostatus, and conditioning intensity. Relapse was considered a competing event for TRM. The predictive benefit of adding the laboratory markers to the HCT-CI score was estimated by calculating the area under the receiver operating curves (AUC) of TRM prediction models, with and without the markers.

Results: Patients had a median age of 55 years and HCT-CI scores of 0 (24%), 1-2 (39%), and >=3 (37%). A cut-off of CrCl<60 ml/min, albumin<3.5 g/dl, and Alk-p>180 IU/l corresponded with 8.8%, 8.3%, and 6.5% of the population, respectively. CrCl and albumin were associated with increased risk and higher cumulative incidence of day-100, 1-year, and 2-year TRM, regardless of whether they were continuous or categorized (Figure-panel a). A similar pattern was observed with Alk-p, except for day-100 TRM. In a multivariate analysis, a CrCl<60 ml/min and albumin <3.5 g/dl were consistently among the top risk factors for early and late term TRM. Hazard ratios for 2-year TRM of CrCl<60 ml/min and Albumin <3.5 g/dl were 2.00 (1.37-2.95) and 2.329 (1.58-3.43). Interestingly, age did not meet statistical significance in models incorporating these biomarkers, suggesting they strongly reflect patients' physiological status. Alk-p was dropped out in the multivariate analysis. Prediction models for day-100 and 2-years TRM, based only on HCT-CI, had AUCs of 56.4 and 58.6, respectively. The introduction of both albumin and CrCl, separately or combined, resulted in incremental improvement in AUC, topping at 66.1 (+17% increase) and 63.2 (+8% increase), for day-100 and 2-years TRM, respectively (Figure-panel b). The improvement was maintained in all conditioning and donor subgroups.

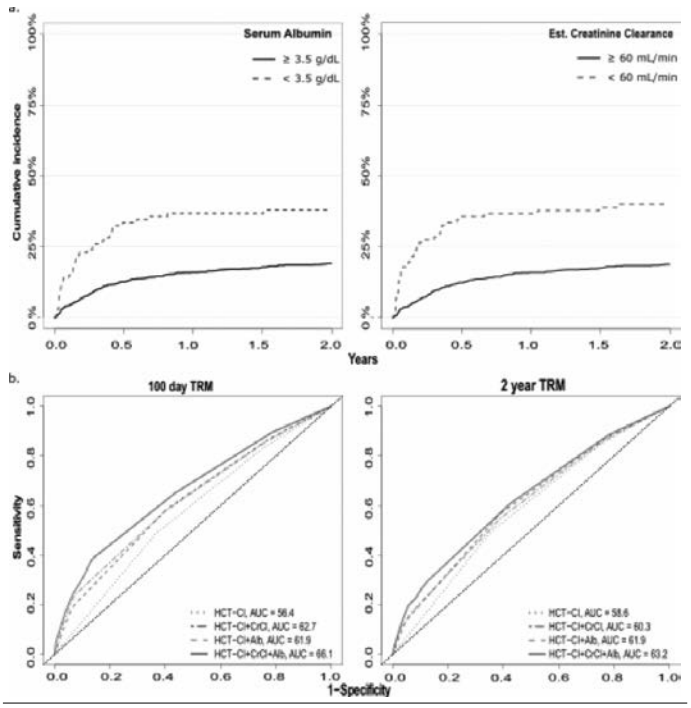

Figure 1.

Summary/Conclusions: Pre-transplantation CrCl and albumin are powerful risk factors for TRM. Deviations from normal ranges were frequent in our cohort, making them useful prognostic markers. We report for the first time the role of CrCl in HSCT prognostication, rather than the traditional HCT-CI cut-off of Creatinine >2mg/dL, which is rare in HSCT population (<1% in our cohort). We also corroborate albumin's important prognostic role. Incorporation of these simple biomarkers can improve pre-transplant risk stratification and potentially be used as a tool for treatment personalization.

E1505

CYTOGENETIC AND MOLECULAR RISK FACTORS AT DIAGNOSIS ARE OVERCOME BY WT1 AND FLOW CYTOMETRY-BASED PRE TRANSPLANT MINIMAL RESIDUAL DISEASE ASSESSMENT IN ADVANCED ACUTE MYELOID LEUKEMIA PATIENTS

[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Division of Hematology and Bone Marrow Transplantation, IRCCS AOU San Martino-IST, Genova, Italy

Background: Allogeneic bone marrow transplantation (BMT) offers the only chance of cure for patients with advanced acute myeloid leukemia (AML). High levels of pre BMT minimal residual disease (MRD) have been reported to predict relapse risk in patient transplanted in first complete remission (CR). WT1 expression levels and multicolor flow cytometry (MFC) are the most common tools to evaluate MRD.

Aims: Here, we analyzed the role of pre-BMT MRD assessment as predictor for the post-transplant relapse risk in patient transplanted beyond first CR.

Methods: We retrospectively analyzed the outcome of 92 consecutive AML patients receiving allo-BMT in 2nd (CR2) or 3rdCR (CR3). Pre-BMT MRD was evaluated by WT1 expression and MFC. Median age at transplant was 45 years. Disease phase was CR2 in 63 patients (68%) and CR3 in 29 (32%). Risk group according to European Leukemia Net (ELN) at diagnosis was low in 28 patients (30%), intermediate in 44 (48%) and high in 20 (22%). Sixty-six patients (71%) received myeloablative conditioning, whereas 26 (29%) were conditioned with reduced intensity regimen. Stem cell source was HLA-identical sibling in 18 (20%), haploidentical (HAPLO) in 24 (26%) and alternative donor in 50 (54%). Median follow-up was 64 months (95% CI 39.8-88.2 months). A positive MFC MRD was defined by the presence of at least $1x10^{-3}$ residual leukemic cells at four or eight (since 2011) color flow-cytometry. WT1 copy

number/Abl copy number 250x10^4 was used as cut-off value for abnormal WT1 expression.
Results: Relapse occurred in 30 patients (33%) and two years non-relapse mortality was 29%. Three-year estimate of OS was 47.9% (median19 months). The survival probability was significantly affected by donor source (better for HAPLO, p<0.05), ELN risk at diagnosis (better for ELN low risk, p<0.01), MRD status before BMT measured with any method (p <0.01 for WT1-based MRD, p<0.03 for MFC based MRD) and CR status at BMT (better for CR2, p<0.05). Specifically patients transplanted in a MRD negative status had comparable OS irrespectively of ELN risk at diagnosis (2-years OS of 62.2% and 52.7% among MFC MRD negative patient with ELN risk low or intermediate/high, respectively, Fig.1). The predictive value of MRD resulted independent from all other analyzed variables, although patients with positive MRD undergoing HAPLO BMT had a slightly better outcome. Multivariate OS analysis revealed that MRD status (evaluated by any method) was the only independent predictor of OS (p <0.05 for both). Pre BMT MRD was also a strong predictor of cumulative incidence (CI) of relapse in competitive risk analysis (p<0.01 and p<0.03, respectively, for WT1 and MFC MRD). Multivariate CI of relapse analysis showed that donor source and MRD significantly influenced relapse risk (p <0.05 and <0.01, respectively).

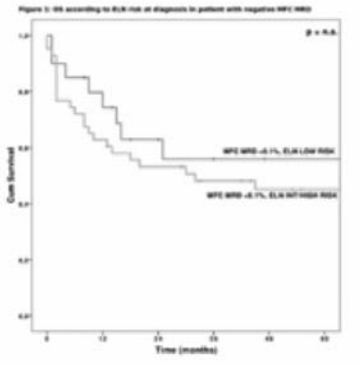

Figure 1.

Summary/Conclusions: Pre transplant MRD evaluated by both WT1 and MFC on bone marrow samples is a reliable predictor of relapse risk and OS which can overcome the ELN risk stratification at diagnosis. Pre BMT MRD negative patients had a significantly better OS, compared with MRD positive ones. MRD positive patients showed an increased risk of relapse, irrespectively of having a low ELN risk at diagnosis. In patients undergoing BMT beyond CR1 pre-BMT MRD status confirms its prognostic relevance and may help in selecting stem cell source. Pre-BMT MRD evaluation may also help in choosing pre-emptive therapeutic strategies.

E1506

IMPACT OF ALLELE SPECIFIC PATIENT:DONOR HLA DISPARITY ON OUTCOME OF REDUCED INTENSITY TRANSPLANTS PERFORMED USING HLA MISMATCHED UNRELATED DONORS: ON BEHALF OF THE ALWP OF THE EBMT

C. Craddock[1,*], M. Labopin[2], D. Niederwieser[3], J. Cornelissen[4], B. Afanasyev[5], P. Jindra[6], J. Maertens[7], D. Blaise[8], P. Ljungman[9], M. Gramatzki[10], A. Ganser[11], B. Savani[12], M. Mohty[13], A. Nagler[14]

Background: Allogeneic stem cell transplantation (allo-SCT) represents an increasingly important curative treatment strategy in adults with acute myeloid leukaemia (AML), consequent upon both the increased availability of unrelated donors and the advent of reduced intensity conditioning (RIC) regimens. Although optimal outcomes are achieved in patients transplanted using an unrelated donor matched at 10/10 HLA A, B, C, DRB1, DQ alleles it remains the case that many undergo transplantation using a donor matched at only 9/10 HLA alleles.

Aims: There are limited data concerning the impact of specific HLA mismatches on patient outcome and we therefore interrogated the EBMT database in order to characterize the impact of mismatch on transplant outcome
Methods: 937 patients with AML in CR1 or CR 2 underwent transplantation utilizing a RIC regimen using a 9/10 mismatched unrelated donor between 2001-2015. Of these 264 were transplanted using a donor mismatched at HLA-A, 127 were mismatched at HLA-B, 292 mismatched at HLA-C, 180 mismatched at HLA-DQ and 74 mismatched at HLA- DRb1. 85% of patients received *in vivo* T cell depletion.
Results: The 2 year leukaemia free survival (LFS) for the whole cohort was 45% and the 2 year overall survival (OS) was 50%. The corresponding non-relapse mortality was 26% and relapse incidence 29%. 30% of patients developed Grade 2-4 acute GVHD and 14% chronic extensive GVHD. In Cox analysis age, adverse karyotype and patient CMV seropositivity were correlated with decreased LFS and OS. There was no significant difference in LFS or OS between patients transplanted from donors mismatched at HLA-A, B, C, DRB1 or DRQ respectively. Of note mismatch at HLA-C was correlated with a lower incidence of acute GVHD but this did not translate into a survival difference. Patient:donor CMV mismatch was associated with a marked increase in transplant related mortality and concomitant reduction in LFS and OS in all groups studied.
Summary/Conclusions: To our knowledge this is the largest to date studying the impact of specific HLA mismatch on the outcome of adults undergoing a RIC allograft from an adult unrelated donor. Recipients of HLA-A, B, C, DRB1 and DQ mismatched allografts demonstrated equivalent outcomes. Patient:donor CMV disparity is an important adverse prognostic factor in HLA mismatched transplants. These data have the potential to inform donor selection in allo-mandatory adults with AML undergoing a RIC allograft who lack a 10/10 matched donor.

E1507

PRE-EMPTIVE THERAPY WITH IFN-A-2B FOR ACUTE LEUKEMIA PATIENTS WITH HIGH RISK OF RELAPSING TENDENCY POST ALLO-HSCT

X. Lin[1], A. Wang[1], F. Chen[1], X. Ma[1], A. Sun[1], X. Zhu[1], H. Qiu[1], Z. Jin[1], S. Xue[1], D. Wu[1,2], X. Tang[1,2,*]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Relapse still remains the most frequent cause of treatment failure and mortality. According to the data of CIBMTR, relapse has become the leading cause of death following allo-HSCT. The high risk patients with more advanced disease, have a relapse rate of 40–80%.Therefore, prevention and treatment of relapse post allo-HSCT is the most likely approach to improve survival of these patients. It is well known that IFN-α had been widely used in the field of antitumor. Recently it is shown that IFN-α also play an important role in immune modulation to enhance the effect of GVL.
Aims: To determine the efficacy and safety of IFN-α-2b pre-emptive therapy for acute leukemia(AL) patients with relapsing tendencies after allogeneic hematopoietic stem cell transplantation (allo-HSCT).
Methods: Retrospectively analyzed 986 acute leukemia patients undergoing allo-HSCT from Jan ,2006 to Mar ,2014 in our hospital. After allo-HSCT, 986 AL patients were periodically monitored the minimal residual disease(MRD) including: bone marrow smear, leukemia-associated immunophenotype (LAIP), leukemia specific or related fusion genes, and donor chimerism through multi-parameter detection to evaluate disease status. Patients were given IFN- a -2b 3 million units / day by subcutaneous injection for preemptive treatment once a relapse tendency was detected, such as: increasing proportion of blast in bone marrow between 3–5%, or MRD>1.0×10^{-3}, or leukemia specific fusion gene transfrom negative to positive, or dynamic incressing copy number of WT1 more than 200 copies/10^4 abl, or decreasing of donor chimerism(≤ 90%). There were 98 patients who presented increasing tendency of MRD and were enrolled in this study. Among them, 31 patients received IFN-α-2b pre-emptive therapy, and 67 patients received non-IFN-α-2b therapy such as: withdraw immunosupressant, traditional DLI or DC-CIK immunotherapy.
Results: There were no significant differences in disease characteristics between two groups. For the 31 patients who received IFN-α-2b pre-emptive therapy(IFN group), the median time of IFN-atreatment was 60 days (range: 5–720 days), Twenty five patients had responsed to the treatment without progressing to hematological relapse (response rate 80.6%). 2 patients developed to hematological relapse again after temporary response; 3 patients had no response and eventually progressed to hematological relapse. Regarding 67patients who received non-IFN-α-2b therapy(non IFN group), 22 patients responsed to the treatment (RR 32.8%), 45 patients failed to the treatment and progressed to hematological relapse at a median time of 35 (range: 6–940) days, There was significant difference of RR between two group(P=0.000). 31 patients of IFN group tolerate well and no patient terminated therapy due to side effects. During the treatment of IFN, 18 patients(58.1%) developed GVHD: 6 patients 19.4% with aGVHD and 14-45.2% with limited cGVHD. The median follow-up time was 21-4.5-78.5 months. 22 of 31 cases of IFN group maintained disease-free survival. The 5-year overall survival rate (OS) and the leukemia-

free survival rate (LFS) of IFN group were 47.0%±13.9% and 38.7%±13.1% respectively. However, the 5-yr OS and LFS of non IFN group were 14.5%±10.7% and12.5%±9.4% respectively.The difference were significantly (P=0.000,P=0.002 respectively). Patients with GVHD had significantly better response than patients without GVHD (88.9% *vs* 53.8%, P=0.043, P <0.05).
Summary/Conclusions: IFN-α-2b pre-emptive therapy can effectively prevent high-risk patients with relapsing tendencies for disease progression post allo-HSCT. Further large-scale investigation is warranted.

E1508

PREDICTING SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION. THE GATMO SCORE

Shaw[12], G. Kusminsky[1]
[1]Hematology, Transplant Unit, Hospital Universitario Austral, Derqui, [2]Hematology, Transplant Unit, Hospital Italiano de Buenos Aires, [3]Hematology, Transplant Unit, Instituto Alexandre Fleming, [4]Hematology, Transplant Unit, Fundacion Favaloro, [5]Hematology, Transplant Unit, Hospital Aleman, Buenos Aires, [6]Hematology, Transplant Unit, Hospiital Italiano de La Plata, La Plata, [7]Hematology, Transplant Unit, FUNDALEU, Buenos Aires, [8]Hematology, Transplant Unit, Hospital Privado de Cordoba, Cordoba, [9]Hematology, Transplant Unit, Sanatorio Anchorena, [10]Hematology, Transplant Unit, Hospital Britanico, Buenos Aires, [11]Clinica Medica, Hospital Universitario Austral, Derqui, Argentina, [12]CIBMTR, Department of Medicine, Medical College of Wisconsin, Milwaukee, United States

Background: Several attempts to predict mortality after autologous stem cell transplantation (ASCT) have been made, like Hematopoietic Stem Cell Transplant Comorbidity Index (HCT-CI) score, originally described by Sorror for allogeneic HSCT. There is no score applicable to the clinical practice that integrates comorbidities with other patient characteristics.
Aims: To describe a comprehensive score that combines comorbidities with other factors and analyse the impact of this score in OS and NRM after ASCT in a cohort of patients transplanted in Argentina.
Methods: We retrospectively reviewed a cohort of 1453 medical records of adult patients who received an ASCT in our centres between October 2002 and August 2016, for Multiple Myeloma or Lymphoma. We compared NRM and Relapse with CI, OS with KM and long term MVA with fine-Gray or Cox regression. We included in the score all the factors that remained significant after MVA for NRM, and assigned a score of 1 if the Hazard ratio (HR) was around 2 (1.5-2.5) and 2 if it was around 3 (2.6-3.5).
Results: Mean age was 50.7 years (range 15-74); 57% were male, 52% had Multiple Myeloma, 29% Non Hodgkin Lymphoma and 19% Hodgkin Lymphoma. Forty-seven percent were in CR, 50% in PR and 3% SD/PD; 14% received three or more chemotherapy lines before transplant (heavily pre-treated). Regarding comorbidities, 62% had low HCT-CI score (score 0), 26% intermediate risk (1-2) and 12% high risk (≥3). Median follow up was 1.1 years (range 100 days-12 years). Early NRM (day 100) was 2.8%, long term NRM (1-3 years) was 4.3-5.8% and OS (1-5 years) was 89-67%. On multivariate analysis risk factors that showed an independent significant impact with NRM and were included in the score were: male patients (1 point), age ≥55 years (1 point), heavily pre-treated (1 point), HCT-CI ≥3 (1 point) and Non Hodgkin Lymphoma (2 points). One hundred and seventy eight patients (12%) had a score of 0, 469 (32%) 1, 381 (26%) 2, 241 (17%) 3, 137 (9.5%) 4 and 47 (3.5%) ≥5. The hazard ratio for NRM increased proportionally with the score (1 2.2, 2 3.5, 3 4.6, 4 10.1 and ≥5 32.3). Patients were grouped as low risk (LR) with a score 0 (12%), intermediate risk (IR) score 1-3 (75%) and high risk (HR) >3 (13%). The score was significantly associated with early NRM (day 100: 1.1% *vs* 1.9% *vs* 9.2 for LR, IR and HR respectively), long term NRM (1-3 years 1.1-1.1% *vs* 2.9-4.1% *vs* 15-20%, respectively, p<0.001) (figure 1) and OS (1-5 years 93-78% *vs* 91-67% *vs* 73-50% respectively, p<0.001) (figure 2). No significant association was observed with relapse rate.

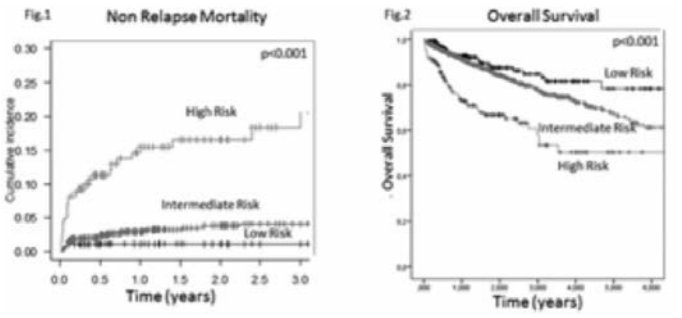

Figure 1.

Summary/Conclusions: We found that GATMO score had a significant association with long term OS due to an increase in NRM. All end-point risks increased proportionally with the score. This observation should be confirmed in larger series.

E1509

A RETROSPECTIVE ANALYSIS OF PATIENT CHARACTERISTICS AND RISK FACTORS FOR ADMISSION TO THE INTENSIVE CARE UNIT (ICU) FOLLOWING HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANT (HDC-ASCT)

L. Jeyaraj Nallathambi[1,*], T. Freeman[1], S. Williams[1], V. Potter[1], R. Benjamin[1], K. Cuthill[1], S. Devereux[1], P. Patten[1], D. Yallop[1], S. kassam[1]
[1]Haematology, Kings college hospital, London, United Kingdom

Background: HDC-ASCT is a standard treatment modality for patients with myeloma and lymphoma. It carries a low, but significant risk of morbidity and mortality. Given that the upper age limit for patient selection continues to increase, it is important to have an objective way of assessing patient suitability for HDC-ASCT. Admission to the ICU is an ominous clinical event post HDC-ASCT and carries a high risk of mortality. There are currently no standard assessment tools to predict the risk of morbidity and mortality.
Aims: To review the incidence and cause of ICU admission in patients receiving HDC-ASCT and identify pre-transplant factors that may be predictive of transplant morbidity and mortality.

Table 1.

Patient characteristics	N=169 (%)
Sex, Male/Female	96/73
Median age, Years (Range)	58 (23-74)
Diagnosis	
Plasma cell neoplasm	122 (72)
Non Hodgkin lymphoma	38 (22)
Hodgkin lymphoma	9 (5)
Conditioning regimen

≥ 50	155 (91)
30-50	6 (3.5)
≤ 30	8 (4.7)

Methods: All patients receiving HDC-ASCT for myeloma and lymphoma at King's College Hospital, London between July 2015 and December 2016 were included. Data cut off was 1st February 2017. Electronic patient records were used to collect data on baseline patient characteristics, comorbidities and performance status. The Charlson comorbidity index (CCI) and haematopoietic cell transplantation comorbidity index (HCTCI) were calculated. Univariate analysis of variables was performed using Graph Pad Prism version 5.03. A p value <0.05 was considered significant.
Results: 169 patients received HDC-ASCT. The median age was 58 years (23-74). Patient characteristics are shown in the table (See Image). Thirteen patients (7.6%) required ICU admission at a median of 14 days post cell infusion (range 5-85), with all patients having a neutrophil count <1x10^9/l. The reasons for ICU admission included sepsis (n=12), severe mucositis/colitis (n=11), renal failure (n=7), hypotension and arrhythmias (n=7), respiratory distress (n=4), liver failure (n=1). The median number of days spent in ICU was 9 (range 2-16). Five patients required single organ support (non-invasive ventilation, 2; inotrope support, 2; haemofiltration; 1) and 2 required only management of

fluid balance. Six patients required multi-organ support (non invasive ventilation/intubation, haemofiltraion and inotropic support) and all died. Four patients died within 30 days of HDC-ASCT and had not engrafted neutrophils at the time of death. Two patients died late at day +120 and day +93 post HDC-ASCT. The latter had both successfully engrafted neutrophils but subsequently became neutropenic. Causes of death were neutropenic sepsis (3), cerebrovascular event (1), hepatitis E (1) and autologous graft *versus* host disease (1). By univariate analysis none of the baseline parameters, comorbidities or conditioning regimens were predictive of ICU admission. The only parameter for which there was a trend for significance was baseline cardiac ejection fraction (EF) <50% (p=0.05). Three patients that required ICU has an EF <50% and 2 were on heart failure medications prior to HDC-ASCT. Two of these 3 patients died.

Summary/Conclusions: In this retrospective series, the risk for ICU admission and death following HDC-ASCT was 7.6% and 3.5% respectively. All patients requiring more than one organ support died. The only predictor of ICU admission may be baseline ejection fraction but this would need confirmation in a larger series. Patient selection remains challenging with no definite tool to predict ICU admission or death.

E1510

AUTOLOGOUS STEM CELL TRANSPLANTATION WITH BENDA-EAM (BENDAMUSTINE, ETOPOSIDE, CYTARABINE, MELPHALAN) IN AGGRESSIVE NON HODGKIN AND HODGKIN´S LYMPHOMA

T. Noesslinger[1], R. Simanek[1,*], M. Panny[1], E. Koller[1], M. Moestl[1], F. Keil[1]
[1]Hematology and Oncology, Hanusch Krankenhaus, Vienna, Austria

Background: Autologous Stem Cell Transplantation (ASCT) is standard of care in relapsed diffuse large B-cell lymphoma (DLBCL) and other lymphoproliferative disorders (relapsed Hodgkin´s disease, 1st line mantle cell lymphoma (MCL) or T-cell lymphoma). BCNU, Etoposide, Ara-C, Melphalan (BEAM) is a standard conditioning regimen, but BCNU is known to be associated with interstitial pneumonia (range 2 to 20%) and an increased risk of death compared with other regimens.
Aims: Therefore a less toxic conditioning protocol might improve the results in lymphoma patients. Bendamustine showed promising results in B- and T-cell lymphoma and dose escalation is safe and feasible. Here we report promising results with bendamustine replacing BCNU in the BEAM regimen described as Benda-EAM, previously published in a phase two dose finding study (Visani, Blood 2011).
Methods: Fourty-one patients with Hodgkin's (HL)(n=9) or Non-Hodgkin (n=32) lymphoma were consecutively treated with Benda-EAM (bendamustine on two consecutive days at a dose of 200mg/m^2 per day). Eleven patients were diagnosed with DLBCL, ten patients with MCL, six patients with follicular lymphoma (FL), three patients with T-cell lymphoma (TCL) and two patients with greyzone lymphoma (GZL). Twenty-seven patients were male and fourteen female with a median age of 52 years (range 22-71) and 25% were above the age of sixty. The median lines of previous therapies were 2 (range:1-4).

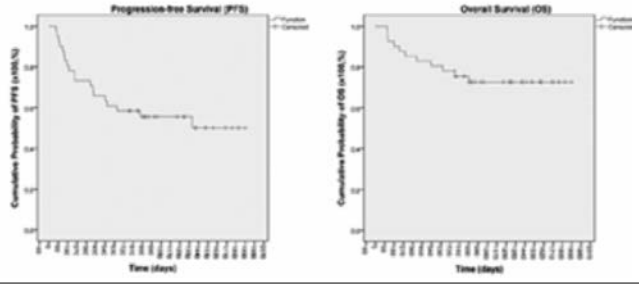

Figure 1.

Results: All patients had chemosensitive disease and before transplantation, 34 patients (83%) were in complete (CR) and 7 (17%) in partial remission (PR). A median number of 4,20*10^{6}CD34+ cells/kg (range: 1,60-13,30) were infused. All patients showed engraftment with a median time to achieve an absolute neutrophil count >1*10^9/L of 10 days (range 8-13) and to platelets >20*10^9/L of 12 days (range 7-110). The median time of fever was 5 days (range: 0-15). The median number of days on G-CSF was 7 (range 4-15) and in median 2 units of red blood cells and 5 units of platelets had to be transfused. The median duration of hospitalization was 25 days.The most common grade 3 and 4 toxicity during the whole treatment period were diarrhea (n=10), mucositis (n=7), infections (n=9) and febrile neutropenia (n=6), followedby nausea (n=4) and cardiologic toxicities (n=3). No severe pulmonary or renal toxicities were observed and no transplant related mortality occurred. After a median follow-up of 43 months 22 patients (56%) are still in CR, while 19 patients (44%) showed progression after a median time of 7 months after transplantation (range 2-29 months). Until today nine patients received an additional allogeneic transplantation. Eleven patients (27%) have died (3 DLBCL, 3 HL, 2 MCL, 1 GZL, 1 TCL and 1 FL), all due to lymphoma progression. Thus the 1- and 2-year PFS are 73.2% and 57.9% and the 1- and 2-year OVS 85.4% and 79.4%, respectively.
Summary/Conclusions: In conclusion Benda-EAM is feasible with a quite promising outcome. Currently an international randomized phase II trial comparing Benda-EAM with BEAM is recruiting. So far fifty-five of 110 planned patients are randomized and first results are expected for 2018.

E1511

THROMBOTIC MICROANGIOPATHY WITH CONCOMITANT AGVHD AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: RISK FACTORS, SEVERE OUTCOME AND TREATMENT EXPERIENCE

X. Liu[1], Q. Wang[1], Y. He[1], X. Zhu[1], J. Zhang[1], L. Xu[1], W. Han[1], H. Chen[1], Y. Chen[1], F. Wang[1], J. Wang[1], Y. Zhang[1], X. Mo[1], Y. Chen[1], Y. Wang[1], Y. Chang[1], L. Xu[1], K. Liu[1], X. Huang[1], X. Zhang[1,*]
[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT)-associated thrombotic microangiopathy (TA-TMA) is a significant complication after allo-HSCT. acute graft-versus-host disease (aGVHD) is one of the risk factors for the occurrence of TA-TMA, and some patients may develop both. Although there has been sufficient information available on aGVHD and TA-TMA, TMA with concomitant aGVHD after allo-HSCT remains not well understood.
Aims: To explore the possible risk factors for the occurrence and mortality of TMA with concomitant aGVHD and to investigate outcomes and treatments of this disorder after allo-HSCT.
Methods: This study was based on patients who underwent allo-HSCT at Peking University People's Hospital from January 2008 to December 2016. We included patients who showed refractory diarrhea and underwent enteroscopy and biopsy. The diagnosis of TA-TMA and aGVHD were mainly made based on the probable-TMA criteria (Byung-Sik Cho *et al.* Transplantation 2010;90:918-926) and endoscopic appearance and histologic findings (Thomas' Hematopoietic Cell Transplantation, Fifth Edition, 2016), respectively. The potential factors affecting TMA with concomitant aGVHD occurrence and markers associated with the death of these patients were identified using univariate and multivariate Cox analysis. The cumulative incidence of relapse, non-relapse mortality (NRM), overall survival (OS) and disease-free survival (DFS) were estimated using the Kaplan-Meier method and were compared by the log-rank test.
Results: Among all 3,992 allo-HSCT recipients, 276 patients showed refractory diarrhea and underwent enteroscopy; of these patients, 50 (1.93%) were diagnosed with TMA with concomitant aGVHD and were enrolled in the case group, and 150 (5.80%) were enrolled in the control group. The two groups matched well with regard to baseline characteristics. Based on the nested case-based control study, grade III-IV aGVHD (P=0.000), AKI (P=0.033) and hypertension (P=0.028) were significant independent risk factors associated with the occurrence of TMA with concomitant aGVHD. Considering the case group only, our data suggested that a haptoglobin level below normal (P=0.013), a maximum volume of diarrhea □2500 ml/d (P=0.015) and bloody diarrhea (P=0.049) were significant markers for death in both univariate and multivariate analysis. Among the case group and control group, the 9-year OS rates were 52% and 81% (P=0.001), respectively; the 9-year DFS rates were 50% and 65% (P=0.345), respectively; the 9-year cumulative incidence rates of NRM were 44% and 16% (P=0.001), and those of relapse were 6% and 19% (P=0.010), respectively. To further study the treatments of patients with TMA and aGVHD, we calculated the OS and found that plasma exchange (PE) use (PE=0, 62.5%; PE 0, 38.9%; P=0.156) had no significant influence on the patient outcome.
Summary/Conclusions: This study demonstrated that patients diagnosed with TMA with concomitant aGVHD after allo-HSCT had a significantly lower OS, higher NRM, and a lower incidence of relapse. The risk factors associated with the occurrence and mortality of TMA with concomitant aGVHD may help us assess the prognosis of patients. The findings also suggested that PE use may be ineffective to these patients.

E1512

SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE MONITORING BY QUANTITATIVE RT-PCR IN CORE BINDING FACTOR AML ON TRANSPLANTATION OUTCOMES

B. Oran[1,*], K. Patel [2], D. Marin[1], Q. Bashir[1], S. Ahmed[1], A. Alousi[1], S. Ciurea[1], J. Chen[1], K. Rezvani[1], U. Popat[1], E. Shpall[1], R. Champlin[1]
[1]Stem Cell Transplantation and Cellular Therapy, [2]Hematopathology, The University of Texas MDACC, Houston, United States

Background: Despite the well-defined role of minimal residual disease (MRD) monitoring in core binding factor (CBF)-AML after intensive chemotherapy, there has been, to date, a paucity of data assessing the clinical utility of MRD monitoring before allogeneic stem cell transplantation (HSCT).
Aims: We investigated the prognostic impact of MRD monitoring by real-time quantitative polymerase chain reaction (RT-PCR) for *RUNX1/RUNX1T1* and

CBFB-MYH11 transcript levels at HSCT on transplant outcomes in AML patients with CBF abnormalities.
Methods: We included 61 AML patients with CBF at diagnosis that underwent their first HSCT in complete remission (CR) from January 2007 through May 2016. Of 61, 19 (31%) had t(8;21) chromosomal translocation and 42 (69%) inv(16)/t(16;16). Diseae status at HSCT was CR1 in 19 (31%) and CR2 in 42 (69%) patients. Hematopoietic stem cell sources were peripheral blood (n=32), bone marrow (n=22) and cord blood (n=7). Conditioning regimen was myeloablative in 38 (62%) and reduced intensity in 23 (38%) patients. Donors were matched related (MR) in 24 (38%), matched unrelated (MUD) in 26 (43%), and haploidentical in 4 (7%). Quantitative real-time PCR analysis was performed on reverse-transcribed RNA for the *CBFB-MYH11(Type A)* and *RUNX1/RUNX1T1* fusion transcripts. Fusion (*RUNX1/RUNX1T1* and *CBFB-MYH11)* and internal control (*ABL1)* transcript levels were detected simultaneously and quantitative results were expressed as the percent ratio of fusion to *ABL1* transcript levels ([fusion/*ABL1*]×100).

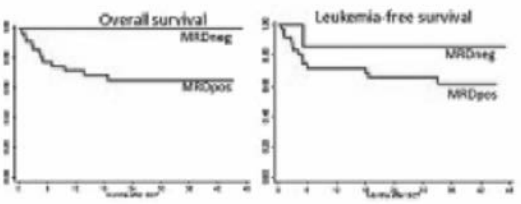

Figure 1.

Results: MRD by RT-PCR at HSCT was evaluable in 43 patients (70%) and 36 of 44 (84%) had evidence of MRD (MRDpos). RT-PCR was <0.1% in 22 patients, ≥0.1% and <1% in 7 and ≥1% in 8 patients. Overall survival (OS) and leukemia free survival (LFS) at 4-years was 100% and 85.7% in 7 MRDneg and 65.4% and 61.6% in 37 MRDpos patients respectively (p=0.09 and p=0.3). The incidence of disease progression was comparable between MRDneg and MRDpos patients, 15% *vs* 16% at 4 years. There was no increase in the risk of progression with higher levels of MRD by RT-PCR (p=0.6). None of the other variables were prognostic for OS, LFS and disease progression.There was no transplant-related mortality observed in MRDneg group while the incidence was 22.6% at 2 years in MRDpos group.
Summary/Conclusions: Durable complete remissions can be achieved in CBF AML patients with HSCT even if they are MRDpos at HSCT.

E1513

LONG-TERM OUTCOME OF ALLOGENEIC STEM CELL TRANSPLANTATION IN ADULT SEVERE APLASTIC ANEMIA WITH ABNORMAL CYTOGENETICS AT DIAGNOSIS

S.-E. Lee[1,*], S. S. Park[1], Y.-W. Jeon[1], J.-H. Yoon[1], B.-S. Cho[1], K.-S. Eom[1], Y.-J. Kim[1], S. Lee[1], C.-K. Min[1], H.-J. Kim[1], S.-G. Cho[1], D.-W. Kim[1], W.-S. Min[1], J. W. Lee[1]
[1]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Cytogenetic abnormalities (CAs) have been reported at the time of diagnosis of acquired aplastic anemia (AA), up to approximately 4-15%. Considering evolution into clonal hematologic disorders and difficulty between AA and hypoplastic MDS, clinical implications of CAs in AA is important.
Aims: In this study, we investigated long-term outcome of allogeneic stem cell transplantation (SCT) in adult severe AA (SAA) patients with abnormal CAs at diagnosis.
Methods: Total of 19 patients with abnormal CAs at diagnosis who underwent allogeneic SCT at our institution between 2003 and 2015. Morphologically hypoplastic bone marrow with dysplastic cells was considered as hypoplastic MDS and excluded. Clonal CAs were defined as 2 or more cells showing the same chromosomal gain or structural abnormality, or 3 or more cells with the same chromosomal loss.
Results: The most frequent abnormality was trisomy 8 (n=11), followed by inversion 9 (n=2). Other CAs included t(3;3), t(5;18), t(1;11), t(1;8), t(1;19), -Y, +Y, -7, +9. Two patients had two or more CAs. Seven male and 12 female patients with a median age of 41 years (range, 20-59 years) were included. Patients had received SCT from HLA-matched sibling (n=12), unrelated (n=5), or haplo-identical donor (n=2). After a median follow-up of 66.3 months (range 12.3-156.3), the 5-year estimated OS rates were 94.7±5.1%. One patient died of acute GVHD. All patients engrafted and three patients developed delayed graft-failure. The incidence of acute GVHD (≥grade II) and chronic GVHD occurred in 4 (21%) and 2 (11%) patients, respectively. Among 16 patients with available follow-up data of cytogenetics after transplantation, 14 patients disappeared CAs with donor-type normal chromosome. However, in two patients, same CAs was observed after transplantation; in one patient with three CAs [+8, +9, and t(1;19)], same CAs was sustained at the most recent follow-up of 23.1 months without morphologically dysplastic cells. In another patient with t(5;18), CA did not detected at 39.2 months but reappeared at 67.5 months, and this CA had disappeared again at 79.6 months. None of patients developed MDS or AML after SCT.
Summary/Conclusions: This study showed that long-term transplant outcomes in SAA patients with CAs at diagnosis were excellent. Moreover, CAs at diagnosis did not affect the clinical outcome including clonal evolution to other hematologic malignancies after SCT in adult SAA.

E1514

PROGNOSTIC VALUE OF PET/CT PRIOR TO AUTOLOGOUS HCT IN RELAPSED / REFRACTORY LYMPHOMA

M. Damlaj[1,2,*], G. Syed[3], G. Gmati[1], H. Salama[1], K. Abuelgasim[1], M. Al-Zahrani[1], S. Ghazi[3], A. Hejazi[3], A. Alaskar[1]
[1]Oncology, King Abdulaziz Medical City, [2]King Abdullah International Medical Research Center (KAIMRC), [3]King Abdulaziz Medical City, Riyadh, Saudi Arabia

Background: Positron Emission Tomography /Computed Tomography (PET/CT) is emerging as a powerful prognostic tool in the management of Hodgkin Lymphoma (HL) and Non-Hodgkin Lymphoma (NHL). A number of retrospective single center cohorts have reported that a positive PET/CT prior to autologous Hematopoietic Stem Cell Transplantation (HCT) is an adverse factor associated with higher relapse risk. However, important heterogeneity is noted in these studies due to differences in timing of PET/CT prior to HCT as well as different metabolic activity threshold (*i.e.* Deauville ≤2 *vs* ≤3). At our institution, we perform PET/CT within 4 weeks prior to HCT and after all intended salvage therapy is administered.
Aims: We sought to further investigate the prognostic value of PET/CT in relapsed / refractory lymphoma patients prior to HCT.
Methods: After due IRB approval, patients who received autologous HCT at our institution for relapsed / refractory lymphoma between 2010 - 2016 were identified. All variables were retrospectively extracted. PET/CT reports were reviewed and metabolic activity was assigned per Deauville criteria. Patients with primary CNS lymphoma were excluded. Refractory disease indicates disease progression prior to completing planned first line therapy. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log ranks. Competing events were computed using Grey's method considering non relapse mortality as a competing event for relapse. Analysis was computed using JMP software, version 11.

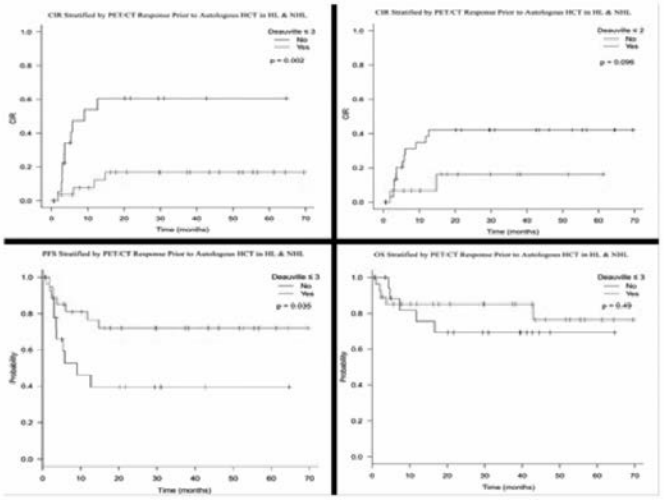

Figure 1.

Results: A total of 53 patients underwent HCT for relapsed / refractory lymphoma with 80% of the cohort having HL. Median follow up of the entire cohort was 26.8 months (0.6-70.5). Cumulative incidence of relapse (CIR), progression free survival (PFS) and overall survival (OS) at 2 years was 37.9%, 56.1% and 74.8%, respectively. A. PET/CT status pre-HCT: A total of 47 patients had pre-HCT PET/CT and were evaluable for further analysis. Median time from PET to HCT was 17 days (6-59). There were no significant differences between the cohorts based on age at HCT, gender, underlying diagnosis, relapsed/refractory status, time to relapse, number of salvage regimens, number of salvage cycles, use of immunotherapy as part of salvage and post HCT immunotherapy use as maintenance. Considering Deauville ≤3 as complete metabolic response (CMR), 2-year CIR was 16.7% *vs* 60.5% for PET negative *vs* PET positive patients (p=0.0021). 2-year PFS was significantly higher in PET negative *vs* PET positive patients at 72% *vs* 39.5%, respectively (p=0.035). 2-year OS was similar irrespective of PET status (p=0.49). Considering Deauville ≤2 as CMR, there was only a trend towards decreased CIR for metabolically negative scans (p=0.096). Significance of these results remained unchanged after excluding NHL cases. B. Relapse post HCT: Median time to relapse post HCT for patients

was 109 days (55-395) *vs* 271 days (55-449) for PET positive *vs* PET negative patients, respectively. Mortality post relapse was 50% with the remaining patients achieving long term disease control with immunotherapy alone (57%), allogeneic HCT (29%) and combination chemotherapy (14%). Median follow up of patients with long term disease control was 1093 days (177-1271). Causes of death post HCT relapse was progression of disease in all cases.
Summary/Conclusions: Despite inherent limitations of this analysis, we present a number of important observations: 1. Deauville score ≤3 is an appropriate cutoff for metabolic activity pre-HCT and is associated with significantly decreased relapse and improved PFS. 2. PET positive status will better identify patients who may benefit from maintenance strategies post HCT. 3. Time to relapse in PET positive patients is significantly shorter highlighting the need for early initiation of pre-emptive maintenance therapy. 4. Long term disease control is possible in a high proportion of patients despite relapse post HCT. These important observations require further study.

E1515

COMPARISON OF OUTCOMES AFTER DONOR LYMPHOCYTE INFUSION WITH OR WITHOUT PRIOR CHEMOTHERAPY FOR MINIMAL RESIDUAL DISEASE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo[1,*], X.-H. Zhang[1], L.-P. Xu[1], Y. Wang[1], C.-H. Yan[1], H. Chen[1], Y.-H. Chen[1], W. Han[1], F.-R. Wang[1], J.-Z. Wang[1], K.-Y. Liu[1], X.-J. Huang[1]
[1]Peking University People's Hospital, Institute of Hematology, Beijing, China

Background: Minimal residual disease (MRD) can predict impeding relapse after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Thus, MRD-directed immunotherapy may be a reasonable option for relapse prophylaxis. Chemotherapy prior to donor lymphocyte infusion (Chemo-DLI) can further decrease the tumor burden, and immunotherapy should preferably be started in patients with leukemia with relatively low tumor burden. However, some patients who are MRD-positive may refuse or are unable to receive chemotherapy prior to DLI. Few studies have compared the clinical outcomes of Chemo-DLI and DLI alone in patients who were MRD-positive after allo-HSCT.
Aims: The efficacy of DLI without chemotherapy was investigated and compared with that of Chemo-DLI in patients who were MRD-positive after allo-HSCT.
Methods: We enrolled 115 consecutive patients who received either DLI (n=20) or Chemo-DLI (n=95) during the same period. For each DLI recipient, three recipients matched for age at the HSCT, underlying diseases, and the year of the HSCT were randomly selected from the Chemo-DLI cohort (n=60).
Results: The 2-year cumulative incidence of severe acute graft-versus-host disease (GVHD) and chronic GVHD was comparable between the groups. Fifteen (75.0%) and 47 (78.3%) patients in the DLI and Chemo-DLI groups turned MRD negative, respectively. The 2-year cumulative incidences of relapse and non-relapse mortality after intervention were 30.7% *versus* 39.6% (*P*=0.582) and 10.3% *versus* 6.0% (*P*=0.508) in the DLI and Chemo-DLI groups, respectively. The 2-year probabilities of disease-free, overall, and GVHD-free/relapse-free survival after preemptive intervention were 58.9% *versus* 54.3% (*P*=0.862), 69.3% *versus* 78.1% (*P*=0.361), and 44.4% *versus* 35.1% (*P*=0.489) in the DLI and Chemo-DLI groups, respectively. In multivariate analysis, the intervention method did not significantly influence the clinical outcomes.
Summary/Conclusions: In summary, preemptive DLI alone may be effective for patients who are MRD-positive and may be a potential alternative for patients who refuse or are unable to receive Chemo-DLI after HSCT.

E1516

DIFFERENTIAL PROGNOSTIC IMPACT OF HEMATOPOIETIC CELL TRANSPLANTATION SPECIFIC COMORBIDITY INDEX (HCT-CI) ON TRANSPLANT OUTCOMES BY STEM CELL SOURCES

Y. Adachi[1,*], K. Sagou[1], Y. Yamaga[1], N. Fukushima[1], K. Ozeki[1], A. Kohno[1]
[1]Department of Hematology and Oncology, Konan Kosei Hospital, Konan, Japan

Background: The hematopoietic cell transplantation specific comorbidity index (HCT-CI) has been proposed to predict the probability of nonrelapse mortality (NRM) and overall survival (OS) in allogeneic hematopoietic stem cell transplantation (HSCT). However, the impact of HCT-CI on clinical outcomes in single unit umbilical cord blood transplantation (UCBT) has not been investigated extensively.
Aims: The purpose of this single-center retrospective study was to investigate the validity of HCT-CI in UCBT.
Methods: We retrospectively analyzed a cohort of 144 consecutive adult patients who received first allogeneic HSCT between July 2008 and December 2016 in our hospital. One patient was excluded from this analysis due to inadequate data regarding comorbidities before HSCT. Patients were divided into the UCBT group (n=90) or the non-UCBT group (n=53). Two-year OS and 1-year NRM were defined as the primary endpoints.
Results: Pre-transplant parameters, such as gender, diagnosis, and the phase of disease, were comparable between the two groups. The median follow-up durations were 562 days and 627 days for the non-UCBT group and the UCBT group, respectively. The most frequent comorbidity was mild hepatic comorbidity (22%), followed by mild or severe pulmonary comorbidities and active infections (16%). For the non-UCBT group, 2-year OS rates for HCT-CI scores of 0, 1-2 and ≥3 were 70% (n=43), 63% (n=30), and 31% (n=17), respectively (P=0.014). For the non-UCBT group, 1-year NRM rates for HCT-CI scores of 0, 1-2 and ≥3 were 10%, 17%, and 35%, respectively (P=0.026). For the UCBT group, 2-year OS rates for HCT-CI scores of 0, 1-2 and ≥3 were 78% (n=26), 46% (n=13), and 69% (n=14), respectively (P=0.38). For the UCBT group, 1-year NRM rates for HCT-CI scores of 0, 1-2 and ≥3 were 9.0%, 15%, and 7.1%, respectively (P=0.75). In multivariate analysis, the HCT-CI score of ≥3 was significantly associated with lower OS (p=0.005; hazard ratio=2.8) and higher NRM (p=0.015; hazard ratio=3.1) for the non-UCBT group, but not for the UCBT group. There was no significant difference in the cumulative incidences of grade 2 to 4 acute GVHD between the non-UCBT group (41%) and the UCBT group (33%, P=0.51). Similarly, there was no significant difference in the cumulative incidences of grade 3 to 4 acute GVHD between the non-UCBT group (6.8%) and the UCBT group (6.1%, P=0.80). The cumulative incidence of extensive chronic GVHD was significantly higher in the non-UCBT group compared with the UCBT group. (38% *vs* 3.8%, P<0.001) Although not significant, patients in the non-UCBT group were more likely to have the systemic steroid therapy compared with those in the UCBT group. (54% *vs* 34%, P=0.064).

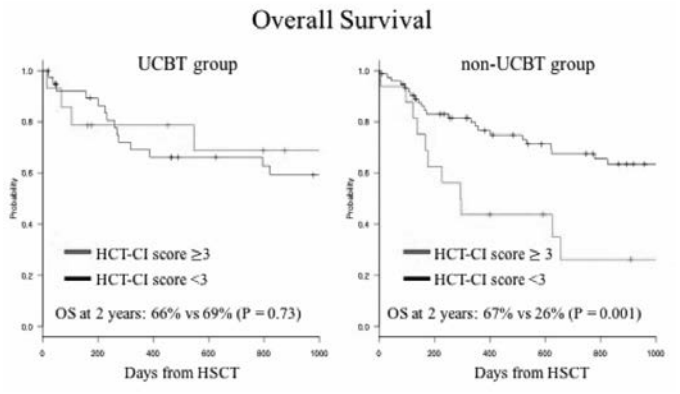

Figure 1.

Summary/Conclusions: UCBT showed good OS with the low incidence of NRM even in patients with high HCT-CI scores. These results indicate that a single unit umbilical cord blood might be a promising stem cell source for patients with multiple comorbidities. Further studies are needed in order to validate these results.

E1517

LOW DOSE POSTTRANSPLANTATION CYCLOPHOSPHAMIDE CAN ENHANCE THE PROTECTIVE EFFECT OF ATG /G-CSF ON GVHD: RESULTS OF A PHASE II PROSPECTIVE TRIAL

Y. Wang[1,*], Y.-J. chang[1], X.-J. huang[1]
[1]Peking university people's hospital, beijing, China

Background: Anti-thymocyte globulin (ATG)/granulocyte colony-stimulating factor (G-CSF)-represented regimen produces essentially universal engraftment with limited relapse and favorable survival, albeit with relatively high rates of graft-versus-host disease (GVHD), especially after HCT from maternal donor or collateral relatives. While use of high-dose, post-transplant cyclophosphamide (PT/Cy) results in low rates of GVHD and favorable immune reconstitution, although with higher rates of relapse and somewhat high rates of graft failure. Thus, novel strategies are needed to refine each approach: under Beijing protocol including ATG and G-CSF, reducing GVHD without abrogating GVL effect is a major priority.
Aims: In order to benefit patients at high risk of developing GVHD without abrogating engraftment and GVL effects, we sought to develop a novel procedure in TCR haplo-HCT with intensified conditioning containing ATG and G-CSF followed by lower-dose of PT/Cy. In addition, the current study attempt to establish a murine model and focus on Treg cells to clarify the immunological mechanisms for GVHD prevention by the new strategy.
Methods: We performed a prospective pilot study of HLA haploidentical cell transplantation (HCT) from maternal or collateral donors with intensified conditioning including G-CSF and ATG, followed by two lower doses of PT/Cy (14.5mg/kgx2 doses; designated as Group A). Outcomes were compared with those of 160 controls from matched-pair analysis who undergone haploidentical HCT from other donors than mother or collateral relatives at the same time period (Group B) as well as with those of 46 historical controls who undergone HCT from mother or collateral relatives at earlier time period (Group C). In addition, the current study attempt to establish a murine model and focus on Treg cells to clarify the immunological mechanisms for GVHD prevention by

the new strategy. Trial registration: The study is registered at www.clinicaltrial.gov as NCT02412423.
Results: We found that low dose PT/Cy combined with ATG could alleviate GVHD in mice and could increase the number of Treg cells while have no effects on CD4+ or CD8+ T cells. A total of 40 patients with myelodysplastic syndrome (MDS) and leukemia undergoing haploidentical HCT from maternal or collateral donors were enrolled in the study. The cumulative, 100-day incidence of acute GVHD, grades II-IV, in Group A (17%; 95% CI, 5%>29%) was significantly lower than both that in Group B (33%; CI, 25%>41%; P=0.04) and that in Group C (56%; CI, 42%>70%; P<0.001). The 1-year probabilities of NRM (5%; CI, 0%>12%), OS (84%; CI, 68%>100%), and LFS (83%; CI, 70%>96%) in Group A were similar to that in Group B, but was significantly lower than that of Group C (28%; CI, 15%>41%; *P*=0.006; 65%; CI, 51%>79%; *P*=0.02; and 65%; CI, 51%>79%; *P*=0.04; respectively).
Summary/Conclusions: Low dose PT/Cy can enhance the protective effect of ATG /G-CSF on GVHD. Conditioning with ATG/G-CSF and low-dose PT/Cy might be a feasible option for patients undergoing HLA haploidentical, T-cell replete HCT, in particular for those with high GVHD risk.

E1518

HEPATITIS B REACTIVATION IN HEMATOPOIETIC STEM CELL TRANSPLANTED PATIENTS: 22 YEARS EXPERIENCE OF A SINGLE CENTRE
A. Murt[1], T. Elverdi[2], A. Salihoglu[2], A.E. Eskazan[2], M.C. Ar[2], S. Ongoren Aydin[2], Z. Baslar[2], T. Soysal[2,*]
[1]Internal Medicine, [2]Hematology, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Reactivation of inactive viruses is an important complication of haematopoetic stem cell transplantation (HSCT). Suggestion of strategies to combat this problem will probably decrease transplant related mortality and morbidity.
Aims: Aim of this study is to evaluate the clinical progress and risk factors for reactivation in HSCT patients who were infected with hepatitis B virus (HBV) with the prospect of developing recommendations for a better clinical care.
Methods: Patient files and electronic records of 561 patients who received HSCT between 1994 and 2015 at the Bone Marrow Transplantation Centre of Cerrahpaşa Medical Faculty were retrospectively evaluated. A total of 66 patients with HBsAg (n=15; 12 autologous, 3 allogeneic) and anti HBc IgG positivity (n=51; 29 autologous, 22 allogeneic) were included in the study. Cases were grouped according to transplant types (allogeneic or autologous) and anti-HBS antibody positivity (anti-HBs positive or negative) to calculate relative risks and cumulative incidences of HBV reactivation.
Results: Four (%26) of the 15 patients with HBsAg positivity showed HBV reactivation in an average of 13 months following HSCT. While cumulative incidence of reactivation was 7% at day 60, it went up to 16% and 44% at days 270 and 730 following HSCT, respectively. In Anti HBc IgG positive group, allogeneic HSCT (n=22) was a higher risk factor for reactivation (31.8%) than autologous HSCT (n=29, 6.8%). Relative risk of reactivation in the allo-transplanted patients who were anti-HBc IgG positive and anti-HBs negative was 6,8 when compared to anti-HBs positive patients (n=9, 55% *vs* n=13, 15%) (95% CI: 1,3-46,5). Cumulative incidence of reactivation in anti-HBc IgG positive anti-HBs negative patients (isolated anti HBc IgG positivity) was 11% at day 10 day, 33% at day 133, 50% at day 400 and going up as high as 75% at day 940.
Summary/Conclusions: The results of our study indicate that HBsAg positive patients undergoing autologous or allogeneic HSCT should receive antiviral prophylaxis at least one year posttransplant. Anti-HBc IgG positive patients carry the risk of reverse seroconversion, with receivers of allogeneic HSCT having higher risk than those of autologous HSCT. Patients who are anti-HBc IgG positive and anti-HBs negative should receive prophylaxis for HBV if allogeneic HSCT is to be performed. However, close follow-up seems to be acceptable rather than a prophylactic treatment for anti-HBc IgG positive patients undergoing autologous HSCT.

E1519

ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION FROM HAPLOIDENTICAL DONOR WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE WAS RELATED TO LESS INPATIENT COST COMPARED TO CORD BLOOD TRANSPLANTATION
N. Kurita[1,*], Y. Yokoyama[1], T. Kato[1], H. Nishikii[1], M. Sakata-Yanagimoto[1], N. Obara[1], Y. Hasegawa[1], S. Chiba[1]
[1]Department of Hematology, University of Tsukuba, Tsukuba, Japan

Background: The number of allogeneic HSCT from alternative donors such as cord blood (CB) and haploidentical donor (haplo) is increasing especially after introduction of post-transplant cyclophosphamide (PT/CY) as GvHD prophylaxis for haplo. Although comparison of the survival benefit between CB and haplo with PT/CY has been made by several groups, there is little information about the medical cost and the hospitalization period of HSCT from alternative donors.
Aims: We evaluated the medical costs and the hospitalization period related to allogeneic HSCT in order to clarify the impact of donor sources and other clinical factors on these outcomes.
Methods: Patients (n=134) with hematological malignancies who underwent allogeneic HSCT between January 2013 and December 2016 in University of Tsukuba Hospital were included. The days of the initial hospitalization (from the beginning of the conditioning regimens to discharge), the whole initial inpatient costs and the costs of transfusion during the initial hospitalization was retrospectively analyzed.
Results: The median age of the patients was 46 (range, 16-67) years. The diagnoses were AML (n=66), ALL (n=31), MDS (n=17), lymphoma (n=11), and others (n=9). Twenty-seven patients were transplanted from MRD, 37 from MUD, 22 from haplo with PT/CY, and 48 with single-unit CB. The median initial inpatient cost was €49179 (IQR, 37030-66923), the median transfusion cost was €11500 (IQR, 9500-15250), and the median length of initial hospitalization was 55 (IQR, 44-75) days. CB showed significantly higher inpatient cost (median, €66852) than haplo (median, €49085, *P*=0.008 *vs* CB), MRD (median, €36998, *P*<0.001 *vs* CB), and MUD (median, €39262, *P*<0.001 *vs* CB) (Figure). Also, the transfusion cost was highest in CB (median, €22750) compared with haplo (median, €12866, *P*<0.001 *vs* CB), MRD (median, €12699, *P*<0.001 *vs* CB), and MUD (median, €13118, *P*<0.001 *vs* CB). The median hospitalization days were 67 in CB, 61 in haplo (*P*=1.0 *vs* CB), 46 in MRD (*P*=0.001 *vs* CB), and 49 in MUD (*P*=0.01 *vs* CB). Among the clinical variables such as diagnoses (acute leukemia or others), refined disease-risk index (low/int or high/very high), donor source (MRD, MUD, haplo, or CB), age, first or second HSCT, intensity of conditioning (RIC or MAC), with or without comorbidity, graft failure, GvHD III-IV, and admission to the intensive care unit (ICU), multiple regression models revealed CB (*P*<0.001), haplo (*P*=0.003), graft failure (*P*<0.001), admission to ICU (*P*<0.001), and MAC (*P*=0.05) were the factors that increased the initial inpatient cost. The transfusion cost was increased by CB (*P*<0.001), graft failure (*P*<0.001), admission to ICU (*P*<0.001), and MAC (*P*<0.001). CB (*P*<0.001), haplo (*P*=0.003), and GvHD III-IV (*P*=0.01) were selected as factors associated with longer hospitalization period.

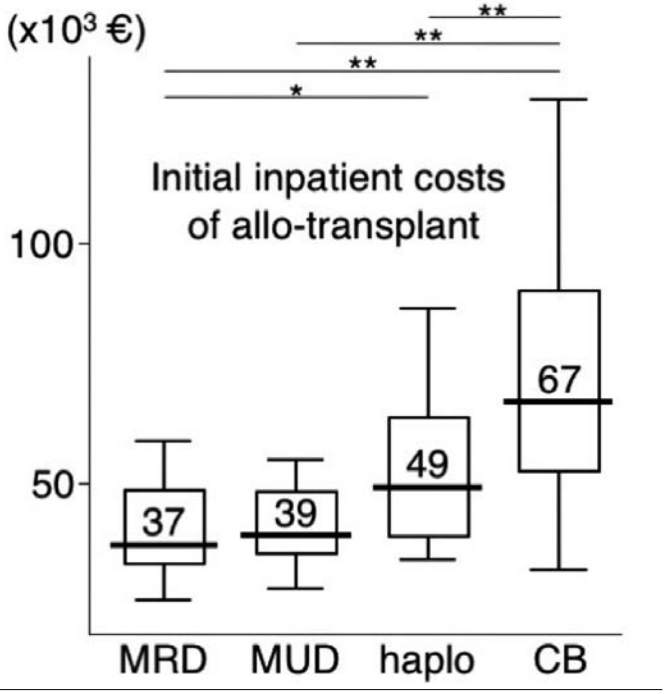

Figure 1.

Summary/Conclusions: Although HSCT from alternative donors was related to the higher initial inpatient cost and longer hospitalization, the impact on those outcomes was more significant in CB than haplo with PT/CY. The higher inpatient cost of CB was partly attributed to delayed hematological recovery which lead to its larger demand for transfusion. The strategy to improve hematological recovery will be needed to reduce the medical cost especially in CB. The larger scale investigation is necessary for better cost-effectiveness in HSCT.

E1520

THE ROLE OF PPARΓ EXPRESSION IN PATIENTS WITH AGVHD FOLLOWING ALLO-HSCT
X. Wu[12,*], J. Zhang[1], S. Ma[1], Y. Ji[1], J. Xu[1], Y. Xie[1], Y. Han[1], X. Tang[1], C. Fu[1], D. Wu[12]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: The acute graft *versus* host disease (aGVHD) is the main com-

plication after allogenic hematopoietic stem cell transplantation (allo-HSCT). Peroxisome proliferator-activated receptor (PPAR)-gamma (γ), a potent anti-inflammatory agent□is a transcription factor belonging to the nuclear hormone receptor super family which may be participating in aGVHD.
Aims: To explore the role of PPARγin aGVHD after allo-HSCT.
Methods: 65 patients under allo-HSCT and 10 healthy controls were enrolled in study. Peripheral blood (PB) of patients was collected at 15 days, 30 days, 60 days, and 90 days after allo-HSCT. The mRNA expression of PPARγ, IFNγ, T-bet was detected by the real-time PCR. Furthermore, we conducted mixed lymphocyte reaction (MLR) to detect the proliferation of active lymphocytes under different concentration of PPARγ agonist.
Results: Among 65 patients after HSCT, aGVHD occurred in 45 patients. Expression of PPARγ mRNA in healthy controls were significant lower than that in patients after allo-HSCT within 90 days (P<0.05). The expression of PPARγ mRNA hold steady in non-GVHD patients within 90 days after allo-HSCT, and was significantly lower in GVHD group than in non-GVHD group (P<0.05). PPARγ expression in severe aGVHD (grade 3 to 4) was lower than mild aGVHD (grade 1 to 2) patients (P<0.05). The expression of IFNγ and T-bet increased in aGVHD patients and were negatively correlated with PPARγ mRNA expression (P<0.05). The experiment of MLR shows that PPARγ agonist rosiglitazone above concentration of 25μM had dose-dependent inhibition effect to proliferation of lymphocytes.
Summary/Conclusions: Low expression of PPARγ is associated with aGVHD occurrence and degree. PPARγ agonist can inhibit the proliferation of lymphocytes, which may be a new way to treat aGVHD.

E1521

HAPLOIDENTICAL TRANSPLANTATION WITH MYELOABLATIVE CONDITIONING REGIMEN COULD SERVE AS AN OPTIONAL SALVAGE THERAPY FOR YOUNGER PATIENTS WITH REFRACTORY OR RELAPSED NON-HODGKIN LYMPHOMA

H. Huang[1,*], X. Xiao[1], Z. Jin[1], D. Wu[1]
[1]Soochow University, Suzhou, China

Background: Allogeneic hematopoietic stem-cell transplantation (allo-HSCT) has a well-established role in the treatment of refractory or relapsed (R/R) aggressive non-Hodgkin lymphoma (NHL). However, whether patients with R/R aggressive NHL, in the absence of appropriate HLA-matched donors, can benefit from haploidentical hematopoietic stem cell transplantation (haplo-HSCT) is yet to be elucidated. Herein, we evaluated clinical outcomes of haplo-HSCT in patients with R/R aggressive NHL.
Aims: To evaluated clinical outcomes of haplo-HSCT in patients with R/R aggressive NHL.

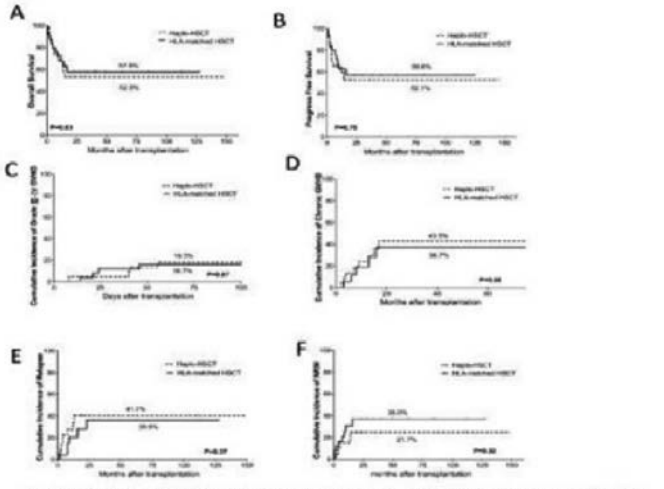

Figure legend: Comparison of outcomes after haplo-SCT and HLA-matched SCT. (a) Overall survival, (b) Progression-free survival, (c) Cumulative incidences of grade III-IV acute GVHD, (d) cumulative incidences of chronic GVHD, (e) cumulative incidences of relapse, (f) cumulative incidences of non-relapse mortality.

Figure 1.

Methods: 23 patients with R/R aggressive NHL who had undergone haplo-HSCT in our center between January 2004 and December 2015 were included, and data were retrospectively analyzed. 25 patients with R/R aggressive NHL who received HLA-matched HSCT during the same period constituted the control group for this analysis. All patients received myeloablative conditioning (MAC) regimen. Antithymocyte globulin (ATG) was administered to prevent graft-versus-host disease (GVHD). The median age of patients who underwent allo-HSCT was 33 years (range, 16-58). Twenty-three patients had received transplant from haploidentical donors, while twenty-five patients received transplant from HLA-matched donors, of which included 13 ISD and 12 MUD. Chemoresistant disease at transplantation was more common in the haplo-HSCT group as compared to that in the HLA-matched HSCT cohort (*P*= 0.005). No significant between-group differences were observed with respect to distribution of age and sex, histological subtype, bone marrow involvement, aaIPI score, chemotherapy regimen and relapse after ASCT.
Results: Median age of patients at allo-HSCT was 33 years (16-58). Over a median follow-up of 23 months, 27 out of the 48 patients (56%) were alive. Progression free survival (PFS) rate at 2-years in the haplo-HSCT and HLA-matched HSCT groups was 52.1% and 56.6%, respectively (P=.75); 2-year-overall survival (OS) rate was 52.8% and 57.8%, respectively (P=.83). Cumulative incidence of relapse (RI) was 41.7% and 35.5% (P=.37), while non-relapse-mortality (NRM) was 21.7% and 35.0%, respectively (P=.32). Collectively, these results showed no significant difference with respect to major allo-HSCT endpoints between the haplo-HSCT and HLA-matched-HSCT groups. On multivariate analyses, older age (> 45 years), primary chemorefractory disease, and occurrence of grade III-IV aGVHD were associated with poor prognosis in both groups. Likewise, the most important factors that influenced the overall survival rate in the haplo-HSCT group were age and occurrence of grade III-IV aGVHD.
Summary/Conclusions: Haplo-HSCT with MAC regimen could serve as an optional salvage therapy, with outcomes comparable to those of HLA-matched HSCT, particularly in younger patients with R/R NHL without appropriate donors.

E1522

OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA HARBORING INV(3)/(Q21;Q26.2)/T(3;3)(Q21;Q26.2)

J. Aoki[1,*], K. Ishiyama [2], N. Uchida[3], T. Fukuda[4], K. Ohashi[5], M. Hidaka[6], N. Kobayashi[7], T. Sakura[8], N. Aotsuka[9], H. Okumura[10], T. Ichinohe[11], J. Tanaka[12], Y. Atsuta[13,14], S. Yano[15]

Background: Acute myeloid leukemia (AML) with inv(3)/(q21;q26.2)/t(3;3)(q21;q26.2) [inv(3)/t(3;3)] is categorized as AML with recurrent genetic abnormality in the WHO classification, accounts for approximately 1%-2% of AML, and is characterized by resistance to chemotherapy and poor outcomes. Therefore, the presence of this chromosomal abnormality in AML is an indication for allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, outcomes of AML with inv(3)/t(3;3) remain unclear.
Aims: We retrospectively examined the impact of inv(3)/t(3;3) on the outcomes of allo-HSCT in patients with AML.
Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. We selected patients with AML harboring inv(3) /t(3;3), who were aged ≥16 years and underwent their first transplantation between January 2000 and December 2014. We analyzed outcomes such as overall survival (OS), relapse, and nonrelapse mortality (NRM) for the patients underwent allo-HSCT. OS was estimated using the Kaplan-Meier method and compared using the log-rank test. Relapse and NRM were considered as competing risk and were compared using the Gray's test. In a multivariate analysis, the Cox proportional hazard model was used to analyze OS, using the following variables: age, sex, disease status at allo-HSCT, time taken for allo-HSCT from diagnosis, donor source, conditioning regimen, additional monosomy of chromosome 7 or partial depletion of long arm of chromosome 7 and type of 3q abnormality.
Results: Of 15025 patients with AML who were aged ≥16 years and who underwent their first transplantation, inv(3)/(q21;q26.2)/t(3;3)(q21;q26.2) was identified in 66 patients. The median age was 46 years (range, 16-72 years). Of the 66 patients, 10 (15.2%) were in first complete remission (CR1) at allo-HSCT, 54 (81.8%) were in non-CR, and the disease status of two patients was unknown. The probabilities of 2-year OS, relapse, and NRM were 27.8% (95% CI, 16.8-40.0), 64.2% (50.4–75.0), and 21.1% (11.8-32.3), respectively. Multivariate analysis revealed that an age of ≥50 years (HR, 2.05; 95% CI, 1.06-3.99; P =0.03) was significant risk factors for poor OS. Non-CR at transplantation (HR, 2.55; 95% CI, 0.94-6.93; P=0.07), and reduced conditioning intensity

(HR, 2.03; 95% CI, 0.99-4.14; P=0.05) were risk factor with marginal significance for poor OS.
Summary/Conclusions: These findings revealed that AML with inv(3)/t(3;3) had dismal outcome even after allo-HSCT. Multivariate analysis suggested that a myeloablative conditioning regimen might improve the transplantation outcome.

E1523

PHARMACOKINETICS (PK) OF PROPYLENE GLYCOL-FREE MELPHALAN HCL (PG-FREE MEL) IN MULTIPLE MYELOMA (MM) PATIENTS UNDERGOING AUTOLOGOUS TRANSPLANTATION (AHCT)

P. Hari[1,*], B. Dhakal[1], A. D'souza[1], R. Thompson[1], M. Hamadani[1], M. Pasquini[1], S. Chhabra[1]
[1]Medical College of Wisconsin, Milwaukee, United States

Background: Melphalan (MEL) is the most commonly used conditioning agent in AHCT for MM and exhibits a dose response relationship (Nath CE Br J Clin Pharmacol. 2010 May; 69(5):484). PG-free MEL (Evomela^{TM}) has longer stability in solution, results in a slightly higher systemic exposure compared with standard MEL and eliminates propylene glycol administration during high dose melphalan-based conditioning. This agent was shown to be bioequivalent to conventional melphalan leading to successful myeloablation and engraftment in MM pts receiving AHCT with no transplant related mortality or unexpected toxicity leading to its FDA approval (Hari P Biol Blood Marrow Transplant. 2015 Dec; 21(12):2100). Published studies thus far have used PG-free MEL in 2 consecutive daily doses of 100mg/m^2/day while a single daily conditioning dose of 200mg/m^2 (MEL200) is most commonly used in clinical practice.
Aims: Determine the safety and PK variability of high dose PG-free MEL 200mg/m^2 in patients undergoing AHCT for MM
Methods: Open-label phase II study in which 10 serial blood samples at specific time points for the PK evaluation of melphalan were collected immediately prior to and after receiving single 200mg/m^2 dose of PG-free MEL on day -2 as a 2mg/ml solution. The primary objective was a descriptive analysis of melphalan PK while secondary objectives included the response rates, engraftment and the toxicity and safety profile of PG-free MEL conditioning.
Results: As of Feb 2017, a total of 24 pts. were enrolled (63% male) with a median age of 67 years (range 46-72), including 23 (96%) who received upfront AHCT and 1 (4%) after relapse (Figure 1). High-risk cytogenetics was present in 6(25%) pts 25% were in ISS stage 3. Disease status at transplant was complete remission (CR) in 4 (17%), very good partial remission (VGPR) in 12 (50%) and PR in 8 (33%). AHCT was performed entirely as outpatient in 25%. PK data are available for the first 12 pts at this time. Wide variability in MEL exposure was noted with maximum plasma concentration (Cmax) of 10,100 ng/ml, median Cmax 7750ng/ml (range, 5220-10,100) and median area under the concentration- time curve (AUC) of 561500 ng.min/ml (range, 771000-254000). Mean AUC was 549000 (±155000). No grade 4 non-hematologic toxicities or gastrointestinal toxicities were observed including in patients with Cmax >10,000 (upper quartile of distribution) or AUC>625000. All patients are alive and post-transplant responses in those with at least 100 days of follow up indicate sCR/CR in 60% and VGPR in 30%.

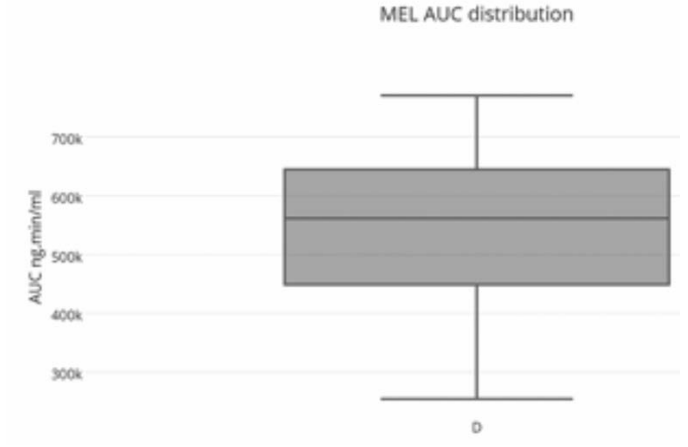

Figure 1.

Summary/Conclusions: PG-Free MEL can be safely administered as a single 200mg/m^2 in conditioning with a favorable toxicity profile. Considerable variability in the PK parameters of high dose MEL indicate that PK directed MEL dosing could be used to optimize MEL exposure. The safety profile of PG-free MEL indicates no increase in mucosal toxicity or adverse events seen even in subjects with highest levels of MEL exposure. For patients in the lowest quartile of AUC, increased PG-free MEL doses up to 20 to 40% over 200mg/m^2 may be safely attempted without additional toxicity if PK directed dosing is used to ensure adequate MEL exposure and utilize the dose response effect of MEL.

E1524

IMPAIRED LYMPHOCYTE RECONSTITUTION AFTER AUTOLOGOUS TRANSPLANT IS ASSOCIATED WITH APOPTOSIS OF CD8+ T CELLS AND PREDICTS ADVERSE CLINICAL OUTCOME

U. Rozovski[1,2,*], B. Tartakovsky[3], S. Frank[4], E. Zigman-Hofman[4], M. Yeshurun[5], S. Trestman[3], E. Naparstek[6]
[1]Hematology, Davidof Cancer Center, Beilinson Campus, Petah Tikva, [2]Tel Aviv University, [3]Hematology, Tel Aviv Sourasky Medical Center, Tel Aviv, [4]Shneider Hospital, Beilinson Campus, [5]Hematology, Davidof Cancer Center, Beilinson Campus, Petah Tikva, Petah Tikva, [6]Hematology, Assuta Medical Centers, Tel Aviv, Israel

Background: In patients undergoing autologous stem cell transplantation (ASCT), faster recovery of the lymphocyte counts has been associated with longer disease-free survival (DFS) and longer overall survival (OS). We noticed that the post-transplant lymphocyte counts fluctuated significantly during the first post-transplant weeks and wondered what the clinical significance of this observation is, and what dictates the lymphocyte counts over time.
Aims: Describe the kinetics of post-ASCT lymphocyte reconstitution in a single patient and across patients. Determine whether activation of anti-apoptotic pathways are associated with faster recovery of the lymphocyte counts.
Methods: We reviewed the medical records of 105 consecutive patients with lymphoma (Non-Hodgkin's' lymphoma and Hodgkin disease) or multiple myeloma who underwent ASCT at Tel-Aviv Sourasky Medical Center and were alive 24 weeks after the transplant. In each patient we documented the absolute lymphocyte counts (ALC) starting 2 weeks after the transplant until the 24th post-transplant week. We used flow cytometry to characterize the lymphocyte sub-populations in lymphocytes derived from 20 randomly selected patients, assayed apoptosis by DiO6 binding and used fluorescence anti-MO2 monoclonal antibody to detect the MO2 epitope by flow cytometry. The probability of OS and of DFS was estimated by the Kaplan-Meier method. The log-rank test was used to compare survival distributions.
Results: The ALC was recorded at least once-weekly between the 2nd and 24th post-transplant weeks for each of the 105 study participants. The median ALC during the first 2- 16 weeks was 1.4 X10^3/μL (range: 0.3 to 4.1) and varied considerably in a single patient. After the 16th week, the ALC stabilized and divided the cohort into those with high (n=54, median =1.9 x10^3/μL, range: 1.3 to 3.1) and low (n=51, median=0.9 x10^3/μL, range 0.15 to 1.25) ALCs. Patients with low ALCs were slightly younger, but in all other patient or disease characteristics there were no differences between the two groups. Remarkably, the CD4+ subpopulation was low across all patients, and the difference in ALCs was primarily in the CD8+ subpopulation which remained low in half of the patients and normal or above normal in others. Interestingly, patients with prolonged lymphopenia had higher rates of apoptosis in freshly obtained lymphocytes and the expression levels of MO2, a CD14-derived epitope that protects the cells from apoptosis correlated with lymphocyte counts. Patients with high ALCs during 16-24 post-transplant weeks had longer DFS (P=.07) and OS (P=.04) compared to patients with low ALCs. In a multivariable analysis low ALC at 16 to 24 post-transplant weeks was the strongest predictor for shorter OS.

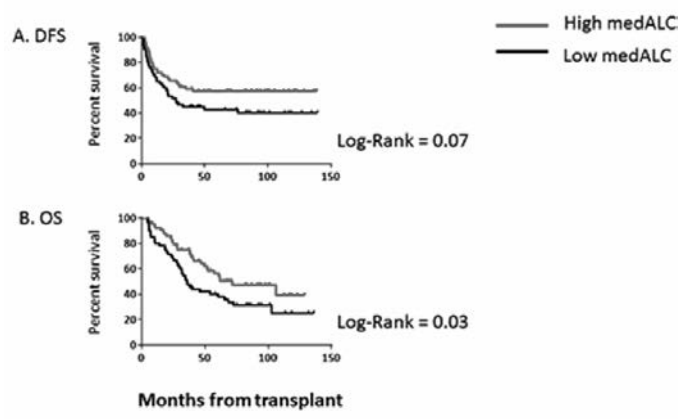

Figure 1.

Summary/Conclusions: The analysis of post-ASCT lymphocyte counts revealed a unique pattern. It fluctuates during the first 4 post-transplant months and stabilizes thereafter, dichotomizing the patients into two groups. In all patients the CD4 subpopulation remained low for at least 6 post-transplant months. However, in half of the patients upregulation of intracellular anti-apoptotic signals was associated with recovery of the CD8+ subpopulation. In the

remaining, both CD4+ and CD8+ subpopulations remained low and these patients were prone to develop relapse. These findings underscore a putative function of CD8+ T-cells in eliminating post-transplant residual disease and maintaining the patients disease free.

E1525

COMPARISON OF TECAM AND BEAM HIGH-DOSE CHEMOTHERAPY FOLLOWED BY AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN LYMPHOMA: EFFICACY AND TOXICITY

F. Sahin[1,*], P. Patir[1], N. Akad Soyer[1], R. Durusoy[2], G. Saydam[1], M. Tobu[1], M. Tombuloglu[1], F. Vural[1]
[1]Hematology, Ege University Hospital Internal Medicine, [2]Public Health, Ege Univeristy, Bornova, Turkey

Background: High-dose chemotherapy conditioning regimens followed by autologous hematopoetic stem cell transplantation (AHSCT) generally provide good results in relapsed and refractory lymphomas.
Aims: Limited data are available to guide the choice of conditioning regimen before AHSCT for patients with lymphoma. We evaluated the efficacy and safety of TECAM and BEAM regimens as conditioning with autologous stem cell support in patients with relapsed/refractory lymphomas.
Methods: From July 2011 to October 2016, 64 pathologically confirmed lymphoma patients underwent AHSCT with BEAM (n=32) or TECAM (n=32) regimens in Hematology Division of Ege University Faculty of Medicine. Patients considered as high risk at diagnosis or with relapsed or refractory diseases were eligible for AHSCT. The two groups were well matched in terms of age, gender, histology. Patients were conditioned with TECAM (thiotepa [40mg/m^2 x four days], etoposide [200mg/m^2 x four days], cyclophosphamide [60mg/kg x one day], cytarabine [200mg/m^2 x four days] and melphalan [60mg/m^2 x two days]) or BEAM (carmustine [300mg/m^2 x one day], etoposide [200mg/m^2 x four days], cytarabine [200mg/m^2 x four days], melphalan [140mg/m^2 x one day]) regimens.
Results: The estimated 22-months overall survival for the TECAM and BEAM groups were 53% and 63%, respectively (p=0.41). The estimated 22-months progression-free survival in the BEAM group (59%) was relatively inferior to the TECAM (74%) group, but the differences were not significant (p=0.98). Cardiotoxicities were relatively more common in the BEAM group. No differences were observed in the time to hematopoietic recovery, the duration of hospitalization, hematological and nonhematological toxicities.
Summary/Conclusions: We conducted a single-center retrospective on lymphoma patients undergoing AHSCT, comparing efficacy and toxicity of TECAM and BEAM conditioning regimens. These two regimens are all optional high-dose chemotherapy with favorable efficacy and acceptable toxicity.

E1526

GENETIC MARKERS OF THE NEUTROPENIA DURATION AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

E. Nazarova[1,*], M. Horobryh[2], V. Shardakov[1], V. Dem'janova[1], N. Zorina[2], N. Minaeva[3], I. Paramonov[3]
[1]Laboratory of Immunology of Leukemia, [2]Department of chemotherapy and bone marrow transplantation, [3]Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: The successes achieved in the treatment of multiple myeloma (MM) in the past few years, associated with the use of high-dose chemotherapy, and with the use of new drugs. Using high-regimes with subsequent autologous hematopoietic stem cells (auto-HSCT) has increased both overall and progression-free survival of patients with MM, as well as improved quality of life. In most cases, patients in the early post-transplant period have severe toxic and infectious complications of varying severity that requires resource-intensive supportive care. The duration of the period of hematopoiesis hypoplasia is dependent on many factors, and an average of 14-16 days. In turn, the attachment of infectious complications in some cases adversely affect the duration of neutropenia.
Aims: To evaluate the possible association of the immune response genes mutation status to the duration of neutropenia after autologous transplantation of peripheral blood stem cells in patients with multiple myeloma.
Methods: The study included 19 patients with multiple myeloma at the age of 32 to 67 years (median - 52 years) who underwent autologous transplantation of hematopoietic stem cells after conditioning regimen with high-dose melphalan. Among surveyed: 8 men and 11 women. In accordance with staging for Durie-Salmon (DSS) system in patients following stages of MM were installed: stage 1A in one patient (5.2%), stage 2A - in 12 patients (63.2%), stage 2B - in two patients (10.5%) and stage 3A - in four patients (21.1%). In the pre-transplantation period partial remission of the disease was achieved in seven patients (36.8%), very good partial remission - in eight patients (42.1%) and complete response in four patients (21.1%). Genotyping of polymorphisms of the innate immune response genes *TLR2* (rs5743708), *TLR3* (rs3775291), *TLR6* (rs5743810), *TLR9* (rs5743836), *IL1β* (rs2856841), *IL2* (rs2069762), *IL4* (rs2243250), *IL6* (rs1800795), *IL10* (rs1800871), *IL17A* (rs2275913), *CD14* (rs34424920), *TNFα* (rs1800629), *FCGR2A* (rs1801274) was performed by polymerase chain reaction with allele-specific primers (Liteh, Russia) at the time of diagnosis.
Results: Depending on the duration of the neutropenia period all examined are divided into two groups. The first group included 10 patients with MM who have early observed recovery (within the first 13 days, 11-13 days), the number of leukocytes ≥1000 cells per ml after auto-HSCT. The second group consisted of nine patients with agranulocytosis held more than two weeks (≥14 days, 14-19 days). When comparing the genotyping data found that a longer period of neutropenia after autologous HSCT was significantly associated with the presence in genotype of MM patients homozygous wild-type allele A gene *IL17A* at position -197 (OR 13.15, 95%CI: 0.60-288.34, *p*=0.03) and with a predominance of heterozygous mutant allele C of the gene *IL1β* at position -31 (OR 8.17, 95%CI: 1.03-67.94, *p*=0.04).
Summary/Conclusions: Our findings point to immune response genes involved in the rate of recovery of hematopoiesis in MM patients after autologous HSCT. Identification of the wild-type allele in intron gene *IL17A (G-197A)* and mutant allele in intron gene *IL1β* (T-31C) will predict the risk of prolonging the period of agranulocytosis and, consequently, the risk of post-transplant complications, and develop a personalized strategy of managing them.

E1527

SUCCESSFUL TREATMENT WITH GRANULOCYTE TRANSFUSION AND EARLY NEUTROPHIL ENGRAFTMENT IN ALLOGENEIC TRANSPLANT PATIENTS WITH FEBRILE NEUTROPENIA

A. Ünal[1,*], L. Kaynar[1], N. Keni[1], A. Birekul[1], E.E. Turak[1], S. Sivgin[1], B. Eser[1], M. Çetin[1]
[1]Erciyes University Medical School, Kayseri, Kayseri, Turkey

Background: Febrile Neutropenia is very severe and urgent early complication after bone marrow transplantation before engraftment. Infection delays engraftments. In this study we retrospectively evaluated the effect and outcome of Granulocyte transfusion on febrile neutropenia and neutrophil engraftment in patients receiving allogeneic transplantation.
Aims: Between 2015-2016, five patients receiving allogeneic bone marrow transplantation (BMT) were treated with granulocyte transfusion at the time of febrile neutropenia before engraftment. The reasons for the use of the granulocyte transfusion were prolonged febrile neutropenia episode.

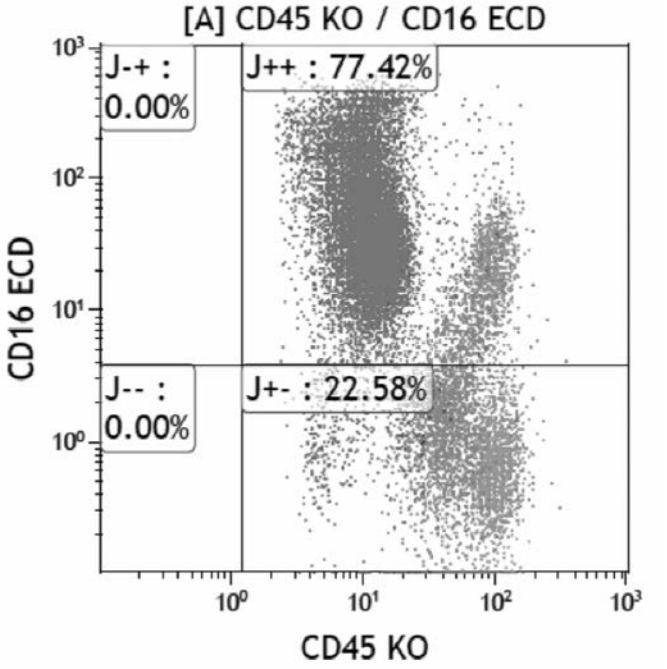

Figure 1.

Methods: Five AML patients underwent allogeneic transplantation. Three of them transplanted from match sibling donors, one from unrelated donor, and one from (7/10) mismatch mother (haploidentic transplant). They had febrile neutropenia after transplantation, before engraftment. They were given antibiotics. Before the granulocyte transfusion, on the 13th-18th days of transplantation, their neutrophil counts were 0.03-0.08x10^3/dl.
Results: We started Granulocyte transfusion for three days. Granulocyte was collected from unrelated and same blood groups donors. Mean infused gran-

ulocyte counts were 3.6x10^10 (1.3-4.6x10^10)/day. Twenty-four hours after granulocyte transfusion, mean neutrophil counts were 0.6x10^3/dl (0.4-0.8x10^3/dl). Neutrophil counts were 2.6 x 10^3/dl, (1.7-2.6x10^3/dl), after 48 hour. After 72 hours, neutrophil counts were 3.4x10^3/dl. (2.1-4.5x10^3/dl). After 4th days of granulocyte transfusion, neutrophil counts were normal levels (>0.5x10^3/dl.).
Summary/Conclusions: Granulocyte transfusions during the febrile neutropenia, helped to better-overcome febrile neutropenia periods in allogeneic transplant patients before engraftment. In addition, granulocytes transfusion also may help early neutrophil engraftments.

E1528

DEFIBROTIDE FOR THE PREVENTION AND TREATMENT OF HEPATIC VENO-OCCLUSIVE DISEASE AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION; A SINGLE CENTER EXPERIENCE

B. Antmen[1,*], I. Sasmaz[1,2], B. Karagun[1], M. Serbest[1]
[1]Pediatric Bone Marrow Transplantation Unit, Department of Pediatric Hematology, Adana Acibadem Hospital, [2]Pediatric Hematology, Cukurova University, Adana, Turkey

Background: Hepatic veno-occlusive disease (VOD) is a common and serious complication of hemotopoietic stem cell transplantation (HSCT) in children. We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.
Aims: We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.
Methods: In this study, 113 patients who underwent HSCT were given defibrotide prophylaxis as 25mg/kg per day in four divided intravenous infusions over 2h, starting on the same day as the pretransplantation conditioning regimen. The mean duration of use of defibrotide is 25 days as a prophylaxis.
Results: In this study, 113 patients were recruited, 66 male patients and 47 female patients, with the average of 9.1 years, range 1-20; 8% infants, 55% children and 37% adolescent. There were 50 patients with thalassemia major, 41 patients with leukemia, 11 patients with aplastic anemia, one patient with Diamond Blackfan anemia, two patients with congenitale dyserythropoetic anemia, one patient with osteopetrosis, four patients with famial hemophagocytic lymphohistiocytosis, two patienrs with severe immune deficiency and one patient with Kostman syndrome. All transplants were allogeneic. No serious side effects were seen. In eight patients developed clinical VOD (Seattle criteria). In these patients, defibrotide dose was increased to a treatment dose of 40-60mg/kg per day. One infant patient with Kostman syndrome died due to hepatic and pulmonary veno-occlusive disease. After 36 months of follow up, 7 patients who developed VOD are being well and no patient have transplant related complications.
Summary/Conclusions: Hepatic veno-occlusive disease, which is caused by hepatocyte and sinusoidal vessel endothelium damage, can ocur early after HSCT, and in its severe form, may lead tol iver faillure, hepatorenal syndrom, portal hypertension, and eventually death from multiorgan faillure. In this prospective study, we demonstrated that the use of defibrotide is safe and effective in preventing and treating VOD in pediatric patients at high risk.

E1529

ACUTE RENAL IMPAIRMENT IN ALLOGENEIC STEM CELL TRANSPLANT RECIPIENTS, A PREDICTOR OF MORTALITY

A.J. Mahdi[1,*], D. Foxwell[2], G. Scott[1], D. Davies[1], K. Wilson[1], W. Ingram[1]
[1]Department of Haematology, [2]Department of Nephrology, University Hospital of Wales, Cardiff, United Kingdom

Background: Allogeneic stem cell transplant (ASCT) remains the only curative option in many malignant and non-malignant conditions. There remains however a risk of significant morbidity and mortality. One risk, acute kidney injury (AKI), can result from drug toxicity and/or haemodynamic instability from sepsis and/or graft *vs* host disease (GvHD). Existing reports on the impact of AKI have concentrated on patients undergoing mainly myeloablative (MA) conditioning alone, whilst those undergoing reduced intensity conditioning (RIC) transplants have reported outcomes from limited patient numbers.
Aims: To investigate the incidence, causes and consequences of AKI in patients undergoing ASCT, including survival.
Methods: The prospectively maintained database of the South Wales Blood and Marrow Transplant programme which serves 77% of the Welsh population, was interrogated to identify patients undergoing ASCT from January 2010 to December 2015. Patients received ciclosporin as GvHD prophylaxis to 100 days post ASCT and weaned thereafter in the absence of GvHD. Serum creatinine and derived estimated glomerular filtration rate (eGFR) acted as the main assessment of renal function. The Acute Kidney Injury Network classification was used to grade AKI. Causes of AKI were assigned after independent review of clinical notes and relevant laboratory data. Patients undergoing second ASCT were excluded. Statistical analysis was carried out using SPSS, version 23 including COX regression and Kaplan-Meier survival analysis.
Results: A total of 229 patients were identified (MA-n=35, 15%; RIC-n=194, 85%). Acute myeloid leukaemia was the most common indication (n=103, 45%). Mean age at ASCT was 51 years (18-72 years). Median follow up after ASCT was 2.19 years (range 9 days-6.6 years). Overall survival to 100 and 365 days was 93% and 74% respectively. Pre-existing renal impairment was uncommon (mean eGFR 92ml/min, range 45-143ml/min). During the first 100 days, no difference was seen in mean eGFR in survival *vs* non-survival groups (75 and 80ml/min respectively, p=0.23). Amongst all patients, AKI incidence in the first 100 days was greater in the non-survival group (93.2% *vs* 80.6%, p=0.02). On multivariate analysis, AKI event in the first 100 days and HLA mismatch (<8/8) were independent factors predicting mortality (p=0.02 and p=0.04 respectively). Recipient age and gender, ASCT indication, history of hypertension, CMV status, donor sex, stem cell source and conditioning regimen (MA *vs* RIC) were not statistically significant (p>0.05). Within the first year of ASCT, pre-terminal AKI was noted in 29% (n=23) of all patients dying (n=59) with sepsis accounting for the major non-relapse cause of death (n=15). Of the patients alive, only 11 (8%) had chronic renal impairment. Chronic GvHD was associated with these patients (73%) one of whom was dialysis dependent.
Summary/Conclusions: AKI is very common post ASCT. Chronic renal failure is uncommon in long-term survivors. AKI is however a prominent event preceding death. Consistent with other reports AKI and HLA mismatch conferred inferior outcomes. Poor survival from AKI probably reflects physiological strain from other complications (e.g. sepsis and GvHD). Early recognition and treatment of AKI are important measures in the supportive care of patients with AKI.

E1530

PREDICTIVE INDEXES FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION, A SINGLE-CENTER EXPERIENCE

J. Zanabili Al-Sibai[1,*], M.P. Palomo Moraleda[1], A.J. González Huerta[1], T. Arias Fernández[1], L.R. Morais Bras[1], L.F. Ávila Idrovo[1], C. Castañón Fernández[1], A. Solé Magdalena[1], S. González Muñiz[1], A.P. González Rodríguez[1]
[1]Hematology, HUCA, Oviedo, Spain

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is often associated with complications such as graft-versus-host disease (GVHD), resulting in poor outcome, relapse and death. Introduction of reduced intensity conditioning (RIC) regimens and improvements in supportive care, have allowed offering allo-HSCT to more and older patients (pts). A balanced risk-benefit approach of candidates for allo-HSCT is the key for maximized chances of cure with acceptable quality of life.
Aims: Compare the potential utility of two pretransplant predictive models: PAM (pretransplant assessment of mortality; Parimon et al, AIM 2006) and HCT-CI (HCT comorbidity index; Sorror et at, Blood 2005), in our cohort of pts.
Methods: We retrospectively studied 154 pts, 86 (55.8%) were males with a median age of 51 years (range: 15-68), who underwent allo-HSCT in our center between May 2005 and December 2014. Patients' baseline diseases were: acute myeloblastic leukemia (24%), multiple myeloma (22.7%), non Hodgkin lymphoma (11.7%), acute lymphoblastic leukemia (11%), myelodisplasic syndrome (9.1%), chronic lymphocytic leukemia (5.2%), Hodgkin lymphoma (3.9%), aplastic anemia (3.9%), myelofibrosis (3.9%), chronic myeloid leukemia (1.3%), Waldenström macroglobulinemia (1.3%) and others (1.9%). Eighty (51.9%) pts received cells frommatched siblings, seventy (45.5%) from unrelated donor and the remainder haploidentical-HSCT (2.6%). Only 43 (27.9%) pts received RIC regimens. Stem cell source were: peripheral blood (n=86), bone marrow (n=63) and umbilical cord (n=5). Median and maximum follow-up were 31 and 228 months, respectively.

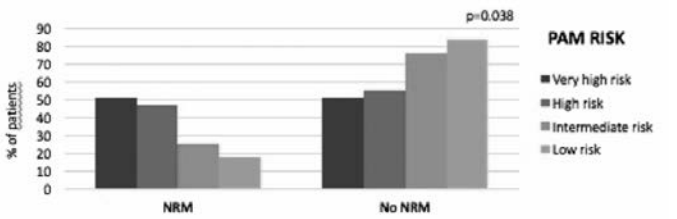

Figure 1.

Results: After allografting, 57.1% pts had complications, the most frequent were: infections (45.5%), followed by nephrotoxicity (25.3%), hepatotoxicity (12.3%), pulmonary toxicityes (9.7%) and cardiotoxicity (3.9%). Eighty-two pertent of pts with high/very high risk group of PAM score presented complications *versus* 46% of pts included in low/intermediate risk (p<0.001). Regarding GVHD, 41.6% and 31.2% of pts developed aGVHD (grades II to IV) and cGVHD, respectively. PAM score was a good predictor for aGVHD risk: 38.1% of pts with low/intermediate risk had aGVHD *versus* 59.3% of pts with high/very high risk (p=0.043). Non-relapse mortality (NRM) was 26%. Causes of NRM included infections (45.8%), hemorrhage (10%), pulmonary toxicities (16%), second neoplasia (14.6%), GVHD (6.25%), cardiotoxicity (2%) and hepatic toxicity (2%). PAM score effectively risk-stratified pts for NRM: 17%, 24.7%, 45.8%, and 50%

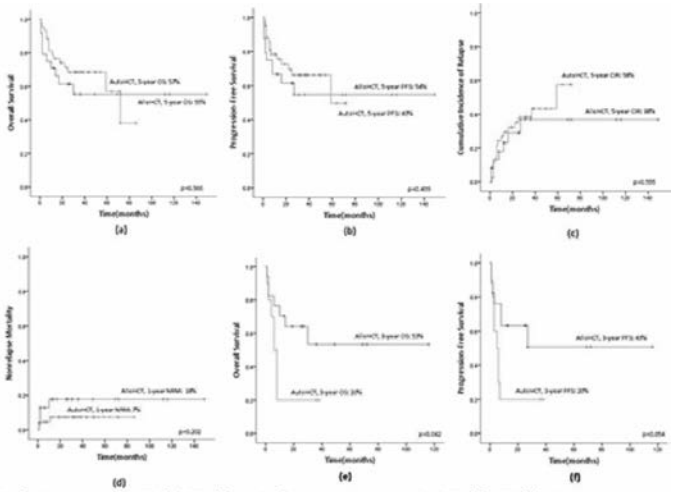
in the low, intermediate, high and very high risk groups, respectively, showing a clear distinction by categories (p=0.038) (figure 1). Refarding relase, 44 (28.6%) pts relapsed. Neither PAM nor HCT-CI were good predictors for relapse. However, HCT-CI was not good predicting complications, GVHD, NRM or relapse.
Summary/Conclusions: In our series of pts, risk-groups based on PAM score provided much better discrimination of post-HSCT complications, aGVHD (II-IV) and NRM than HCT-CI model. None of the indixes were acceptable predictors of relapse. Furthermore, correlation between both indexes was poor.

E1531

ROLE AND TIMING OF HEMATOPOIETIC CELL TRANSPLANTATION FOR HIGH-RISK PERIPHERAL T-CELL LYMPHOMAS

H. Huang[11,*], Y. Jiang[1], Q. Wang[1], T. Xu[1], X. Chen[1], Z. Jin[1], D. Wu[1]
[1]Soochow University, Suzhou, China

Background: Peripheral T-cell lymphomas (PTCLs) often carry poor outcomes with conventional chemotherapy, and hematopoietic cell transplantation (HCT) can benefit patients with PTCL. Recent retrospective studies have reported that autoHCT as consolidation can offer a durable survival benefit in high-risk patients with first complete or partial response, and alloHCT could result in long-term disease control for relapsed and refractory patients.
Aims: To explore questions about the optimal timing for stem cell transplantation and relative efficacy of auto-HCT *versus* alloHCT.
Methods: We conducted a retrospective review of 67 patients with peripheral T-cell lymphoma who underwent autologous HCT (autoHCT, n=43, median age 40 years) or allogeneic HCT (alloHCT, n=24, median age 36.5 years) from 2004 to 2016.
Results: With a median follow-up of 27 months, 5-year PFS and OS of auto-HCT patients were 49% and 57%, respectively. Among alloHCT recipients, the 5-year PFS and OS were 54% and 55%, respectively. When considering incidence of disease relapse or progression (CIR) and nonrelapse mortality (NRM), the 5-year CIR and 1-year NRM of alloHCT recipients were 38% and 18%, respectively, and 58% and 7% of autoHCT patients, respectively. There were no differences between autoHCT and alloHCT on 5-year PFS (*P*=0.499), OS (*P*=0.566), CIR (*P*=0.555) and NRM (*P*=0.202). When specifically examining recipients in primary refractory disease, 3-year PFS rates of autoHCT and alloHCT were 20% and 49% (*P*=0.054), 3-year OS rates were 20% and 53% (*P*=0.042), respectively.



Kaplan-Meier curves for OS (a), PFS (b) and Cumulative incidence curves for CIR (c), NRM (d) for patients who underwent autoHCT versus alloHCT. Kaplan-Meier curves for OS (e), PFS (f) for patients in primary refractory disease who underwent autoHCT versus alloHCT.

Figure 1.

Summary/Conclusions: This analysis shows that HCT can benefit patients with high-risk PTCL in both remission and primary refractory setting. The outcomes did not differ significantly between autoHCT and alloHCT approaches, but alloHCT recipients in primary refractory disease resulted in significantly better outcomes than autoHCT patients. So, we favor proceeding to alloHCT if patients with PTCL in primary refractory disease.

E1532

IMPACT OF BASELINE BILIRUBIN ON SURVIVAL IN PATIENTS WITH HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME RECEIVING DEFIBROTIDE: POST-HOC ANALYSIS OF EXPANDED-ACCESS PROTOCOL FINAL DATA

P. Richardson[1,*], A. Smith[2], B. Triplett[3], N. Kernan[4], S. Grupp[5], J. Antin[6], L. Lehmann[7], S. Giralt[8], W. Liang[9], R. Hume[9], W. Tappe[9], R. Soiffer[7]
[1]Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [2]Division of Pediatric Blood and Marrow Transplantation, University of Minnesota, Minneapolis, [3]Bone Marrow Transplantation and Cellular Therapy, St. Jude Children's Research Hospital, Memphis, [4]Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, [5]Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, [6]Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, [7]Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [8]Memorial Sloan-Kettering Cancer Institute, New York, [9]Jazz Pharmaceuticals, Inc., Palo Alto, United States

Background: Veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is an unpredictable, potentially life-threatening complication of hematopoietic stem cell transplantation (HSCT) conditioning. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved in the European Union to treat severe hepatic VOD/SOS post-HSCT and in the United States to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT. Prior to approval, defibrotide had been available in the United States via an expanded-access program.
Aims: A *post-hoc* analysis of final data from the defibrotide expanded-access program was used to explore Day +100 survival post-HSCT based on bilirubin-level categories at the time of study entry.
Methods: Patients in the defibrotide expanded-access program had VOD/SOS diagnosed by investigators using Baltimore criteria (bilirubin ≥2mg/dL and ≥2 of: hepatomegaly, ascites, ≥5% weight gain), modified Seattle criteria (≥2 of: bilirubin >2mg/dL, hepatomegaly, or ascites and/or ≥5% weight gain), or biopsy; bilirubin >2 was not required for modified Seattle criteria or biopsy. MOD (renal/pulmonary) was permitted. After informed consent, defibrotide treatment (25mg/kg/day) was recommended for ≥21 days. Here, D*ay* +100 survival was explored by bilirubin level at study entry using categories that are part of the European Society for Blood and Marrow Transplantation (EBMT) proposed grading scale for adults (≥2 to <3mg/dL, ≥3 to <5, ≥5 to <8, and ≥8), as well as bilirubin <2mg/dL, which is not part of the scale but has been reported in children with VOD/SOS.
Results: There were 1000 HSCT patients enrolled, between December 2007 and September 2016, with a confirmed diagnosis of VOD/SOS and receiving ≥1 dose of defibrotide, 512 patients had MOD. Median age was lowest in patients with bilirubin <2 (4.5 years; 19% of patients). Median ages were 16 years in the bilirubin ≥2 to <3 group (53.5% of patients) and 13.5 in the ≥3 to <5 group (20.4% of patients); median age in other groups ranged from 15 to 17 years. Kaplan-Meier estimated Day +100 survival in all HSCT patients was 58.9%, with 85.6% in patients with BR <2; other bilirubin groups were older and survival estimates decreased (**Table 1**). In the pediatric (aged ≤16 years) and adult (aged >16 years) patients, patterns were similar (**Table 1**). Estimated survival rates were lower for patients with MOD across all groups. Of all 1000 HSCT patients with confirmed VOD/SOS, 210 (21%) had treatment-related AEs (TRAEs). The TRAEs in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

Table 1. Day +100 Survival (Kaplan-Meier, N=1000).

Bilirubin (mg/dL)	All HSCT Patients		Age ≤16 Years		Age >16 Years	
	n	Survival	n	Survival	n	Survival
<2*	190	85.6%	133	90.9%	57	73.7%
≥2 to <3	535	55.2%	278	63.7%	257	46.2%
≥3 to <5	204	47.2%	120	58.5%	84	31.4%
≥5 to <8	39	53.7%	22	54.2%	17	52.9%
≥8	23	23.9%	11	13.6%	12	33.3%

Summary/Conclusions: This post-hoc analysis found that higher bilirubin levels were generally associated with lower Day +100 survival. These results should be interpreted with caution, as only 1 EBMT criterion was analyzed. MOD was also associated with lower Day +100 survival. The results suggest that diagnosis and treatment of VOD/SOS, before bilirubin becomes markedly elevated, may be associated with improved outcome.

Support: Jazz Pharmaceuticals.

Policlinico Universitario, Udine, Italy, [6]Hematology, Istituto Oncologica Lacassagne, Nizza, France, [7]Hematology, Azienda Ospedaliera di Verona, [8]Hematology, Universita' di Verona, Verona, [9]Hematology, Azienda Ospedaliera Spedali Civili, Brescia, [10]Hematology, Azienda Ospedaliera Alessandria, Alessandria, [11]Hematology, Istituto Europeo di Oncologia, [12]Department of Pathology, Istituto Europoeo di Oncologia, Milano, Italy

Background: The prognosis of patients with newly diagnosed peripheral T-cell lymphomas (PTCLs) is very poor following conventional therapy alone with 5-years PFS ranging from 20% to 30%. From 2006 to 2010, we conducted a multicenter prospective phase II trial to evaluate the efficacy of upfront consolidation of clinical response with autologous (auto) or allogeneic (allo) stem cell transplantation (SCT) in patients at diagnosis. The results were previously reported (4 year PFS of 70% and 69% for auto and allo SCT, respectively) (Corradini P. 2014).
Aims: In this analysis, we extended the follow-up of our trial.
Methods: Sixty-one patients were enrolled after central review pathology [Peripheral T-cell Non Hodgkin Lymphomas (PTCL-NOS) n=33, Anaplastic lymphoma kinase-negative anaplastic large cell lymphomas (ALCL) n=12, Angioimmunoblastic lymphomas (AITL) n=14, enteropathy-associated T-cell lymphomas (EATL) n=2]. The induction therapy consisted of 2 courses of CHOP and alemtuzumab followed by 2 courses of high-dose methotrexate, cytarabine and cyclophosphamide. Patients in clinical remission with HLA identical donors received allo SCT whereas those without a suitable donor received auto SCT. Three patients relapsed after auto SCT and were subsequently allografted (data of last follow-up was censored at date of second transplantation procedure).
Results: Only 37 patients underwent transplantation [autologous SCT (n=14), allogeneic SCT (n=23] whereas 24 did not for toxicity (n=5), progressive disease (n=18) or clinical decision (n=1). In intention to treat analysis, at a median follow-up of 78 months, the estimated 7-years progression-free survival (PFS) and overall survival (OS) for all the patients were 42% (95% CI, 29% >54%) and 41% (95% CI, 28% >53%), respectively. Despite auto or allo SCT consolidation was chosen based on donor availability, the majority of patients allografted had a diagnosis of PTCL-NOS [19 of 23 (83%) *versus* 6 of 14 (43%) autografted, (p=0.02)]. The PFS and OS were not significant different in patients transplanted with a diagnosis of PTCL-NOS as compared to others subtypes but numbers are too small for definitive conclusions [PFS: 48% (95%CI, 32% >62%) *versus* 33% (16% > 51%) (p=0.26); OS: 50% (95%CI, 33% >64%) *versus* 30% (13% >49%) (p=0.36)]. Considering only the patients who underwent a consolidation with any type of transplant (n=37), the PFS were 48% (95% CI, 18% >73%) and 62% (95% CI, 46% >83%) (p=0.40) in patients autografted and allografted, respectively. We did not observe a significant difference in OS between auto or allo consolidation 69% (95% CI ,31% -88%) *versus* 63% (38% >79%) (p=0.51)], but 3 patients in relapse after auto SCT were allografted. The main cause of failure after auto SCT was relapse (6 of 14, last relapse occurring at 81 months after auto). The Crude Cumulative Incidence of non-relapse mortality and relapse after allo SCT were 19% (n=4 deaths, one patient died of cardiac complication 62 months after allo SCT) and 17% (n=4 deaths), respectively.
Summary/Conclusions: The long-term outcome of patients receiving any transplantation strategy remains satisfactory. In the future, biological markers could help physician to select the better therapeutic option for the patients.

E1534

UNRELATED DONOR ATTRITION AT A LATE STAGE: THE BRITISH BONE MARROW REGISTRY EXPERIENCE

K. Balassa[1,2,*], A. Griffiths[3], D. Winstone[1], Y. Li[1], V. Rocha[1,2], R. Pawson[1,2]
[1]British Bone Marrow Registry, NHS Blood and Transplant, Filton, [2]Department of Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, [3]Statistics and Clinical Studies, NHS Blood and Transplant, Filton, United Kingdom

Background: The success of searches for unrelated stem cell donors (UDs) relies on the existence of large international donor registries and the availability and reliability of donors on the register. Donor attrition at the verification typing (VT) or later stage results in delay of transplant and can adversely affect patient outcomes. The British Bone Marrow Registry (BBMR) provides UDs to international transplant centres (TCs) and to UK TCs via the Anthony Nolan registry. Data reported by international registries on donor attrition is scarce and mainly focused on attrition at the VT stage. BBMR donors are recruited from blood donors and may differ in their reliability from non-blood donors included in existing reports.
Aims: To investigate donor attrition rates and causes of cancellation among finally selected or backup BBMR donors at the post-VT stage.
Methods: Data on requests for work-ups from April 2002 to December 2016 were extracted from BBMR databases and donor notes and were analysed retrospectively. The reasons for cancellation were categorised: cancellation initiated by TCs, donor reason or mixed reasons. Within donor reasons we distinguished 3 categories: donor medical reasons, donor withdrawal on personal grounds and inability to contact the donor. We examined associations between cancellations for donor-related reasons and the following factors: donor sex, age at time of donation/cancellation, time on the register and donor reliability score. The reliability score relates to blood donation and runs from 1 (best) to 5 (worst), increasing if a donor fails to attend appointments for blood donation.
Results: A BBMR final/backup donor was selected for 3184 stem cell or lymphocyte collections. 82% of the requests (n=2613) were completed. Out of the 571 (18%) cancelled cases the reason for cancellation was not available for 5 cases. Overall more than half of the cancellations (n=302, 53%) were activated by TCs mainly due to patient death, deterioration or alternative donor choice. Donor reasons accounted for 38% of cancellations (n=216, 6.8% of requested donors), of which 69% (n=148) happened for medical reasons, 27% (n=59) for donor pull-out on personal grounds and 4% (n=9) due to uncontactable donors. The medical reasons for withdrawal were varied but the most frequent health issues were obesity and cardiovascular disease. Analyses of factors affecting donor reasons showed that donor sex and time on the register were not associated with donor fitness or withdrawal rate. Age had no impact on donor pull-out, but it was significantly associated with medical eligibility and donors who failed medically were older (p=0.005). Donor pull-out showed significant association with blood donor reliability score (p=0.029, score 5 *vs* others). In 48 cases (8%) there were mixed reasons where TCs had other donor options and pursued them because of issues such as donor availability for ideal dates or CMV mismatches.
Summary/Conclusions: In our registry patient-related issues accounted for more than half of cancellations at a late stage in the stem cell donor pathway. Cancellations for donor reasons were unusual (6.8% of requested donors), which figure compares favourably with international data (12.4% of requested donors, WMDA Annual Report 2015). This is likely due to the fact that most BBMR donors are regular blood donors: few donors withdrew for personal reasons and very few were uncontactable. Medical conditions were the most frequent cause of cancellation for donor reasons. Further work is underway to allow earlier or reduced deferral of medically unsuitable donors such as control of high blood pressure and to explore personal reasons which cause donors to withdraw. This study should provide reassurance to TCs that BBMR provide reliable and accessible stem cell donors.

E1535

POLIMORPHISM IN TGFB1 GENE PREDISPOSES TO RELAPSE AND DEVELOPMENT OF ACUTE GRAFT-VERSUS-HOST DISEASE GRADES III-IV

N. Meggyesi[1,*], P. Kovy[1], V. Telek[1], K. Balassa[1,2], L. Varga[1], A. Bors[1], P. Remenyi[3], A. Batai[3], E. Torbagyi[3], L. Gopcsa[3], L. Lengyel[3], A. Barta[3], A. Tordai[4], T. Masszi[5], H. Andrikovics[1]
[1]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, [2]School of PhD Studies, Semmelweis University, [3]Department of Haematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, [4]Department of Pathophysiology, [5]3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the most effective treatment option for certain hematological malignancies. Cytokines play a well established role in the mechanism of acute GvHD (aGvHD), which is one of the most significant complications of allo-HSCT. Transforming growth factor B1 (TGFB1) is one of the inflammatory cytokines, which play a pivotal role in the development of aGvHD.
Aims: The aim of this study was to investigate the role of *TGFB1* -1347C>T polymorphism in the outcome of HSCT.
Methods: We examined the association of recipient and donor TGFB1 -1347C>T and allo-HSCT outcome in a cohort of 419 adult patients who underwent first allo-HSCT between January 2007 and December 2013 at our single center. 217 patients received stem cells from their siblings, 202 patients from matched unrelated donors (MUD). For identification of *TGFB1* rs1800469 from genomic DNA LightCycler melting curve analysis (LightCycler 480II, Roche Diagnostics) was performed.
Results: We did not find any association between recipients' *TGFB1* -1347C>T polymorphism and HSCT outcome. However, in patients whose unrelated donors carried homozygous *TGFB1* -1347TT variant, aGvHD grades III-IV occurred more frequently (aGVHD grade III-IV: 28.9% *vs* aGVHD grade 0-II: 9.6%, p=0.006). Similar finding was observed on a subgroup of patients with acute leukemia: in aGVHD grade III-IV 37.5%, while in grade 0-II 11.5% of patients had TT genotype (p=0.022). Donor TT genotype did not influence the relapse rate significantly. Patients with MUD carrying TT genotype had lower overall survival (OS) that that of donors bearing at least one C variant, but the difference did not reach the level of significance (OS at 40 month for CC and CT variant donors: 45.3% and for TT donors: 26.2%). In case of sibling donors, we did not find association between recipient or donor genotype and aGVHD, but relapse rate was increased if donor had at least one T variant (n=115, 67.9% *vs* 32.1%, p=0.028). Significant differences in OS between the subgroups with different genotypes were not observed.
Summary/Conclusions: Our findings suggest that TGFB1 -1347C>T polymorphism in HSCT donors might influence the development of aGVHD in unrelated and the relapse rate in related HSCT.

E1536

EARLY AND LATE LOST OF PROTECTIVE ANTIBODY LEVELS AGAINST MEASLES, MUMPS AND RUBELLA IN PATIENTS GIVEN ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

J. Bögeholz[1,*], E. Haralambieva[2], M.G. Manz[1], U. Schanz[1], A.M. Müller[1]
[1]Hematology, [2]Pathology, University Hospital Zurich, Zurich, Switzerland

Background: Live-vaccines should be avoided in the early period following allogeneic hematopoietic cell transplantation (HCT), due to a possible uncontrolled proliferation of the attenuated strains. The post HCT immune system is severely compromised by pharmacological immunosuppression and disruption of lymphoid tissues by conditioning and donor T cell alloreactivity. Patients frequently lost their antibody-based immunity against measles, mumps, and rubella after receiving allogeneic HCT.
Aims: Here, we studied the dynamics of antibody (AB) titers against measles, mumps, and rubella post-HCT.
Methods: We retrospectively analyzed serial AB titers in 240 patients who underwent allogenic HCT from related und unrelated HLA-matched donors from 2002-2014 at our center. AB titers against measles, mumps and rubella were measured prior to HCT, at 6 months (m), and every year (y) post-HCT.
Results: Most patients had protective AB titers (measles 90%, mumps 86%, rubella 92%) prior to HCT. AB protection against mumps was lost in a substantial proportion of patients after HCT (protective AB titers in 72%@1y, 56%@5y, 50%@8y), comparing to AB against measles, which persist more frequently (protective AB titers in 85%@1y, 74%@5y, 73%@8y). We found a faster lost of protective AB in the first years for patients given a rmyeloablative condition (MAC) in comparison to patients with reduced condition (RIC), but the proportion of seropositive patients became more equal over time (Figure 1 displays the percentage of seropositive patients to Measles AB given MAC or RIC during 8 years post-HCT). The proportion of patients who retained protective AB titers at 5y post-HCT was higher in recipients of mobilized peripheral blood compared with bone marrow (BM) grafts (measles p=0.01, mumps=0.06, rubella p=0.08). For rubella, absolute AB titers were available. Patients with lymphoid malignancies, ongoing GVHD and pharmacological immunosuppression had a steeper decline of rubella AB titers as compared to patients with myeloid malignancies.

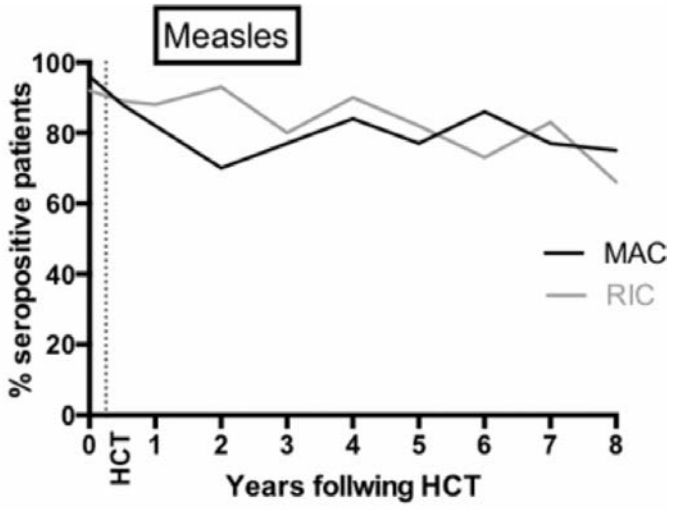

Figure 1.

Summary/Conclusions: We found a marked decline of AB titers post-HCT with loss of protection in a substantial proportion of patients. Surprisingly, BM grafts did not provide better AB protection post-HCT, despite their higher content of (donor) plasma cells. Together with the observations that (i) patients with lymphoid malignancies (who have received (B-) lymphocyte targeted therapies prior to HCT) had lower AB levels, while (ii) those given reduced intensity conditioning have a higher percentage of protective AB levels in the first years, our data suggest, that residual host plasma cells significantly contribute to AB production during the first years post-HCT. In opposite, the loss of protective AB levels in later years after transplantation was independent of the toxicity of the conditioning regime and may be a effect of weakening signaling for host plasma cells or late donor alloreactivity.

E1537

MICA AND NKG2D POLYMORPHISMS HAVE A SIGNIFICANT IMPACT ON GRAFT *VERSUS* HOST DISEASE AFTER HLA-MATCHED HEMATOPOÏETIC STEM CELL TRANSPLANTATION.

M.-J. Apithy[1,*], A. Charbonnier[2], J. Desoutter[1], P. Morel[2], J.-P. Marolleau[2], N. Guillaume[1]
[1]Hematology and Histocompatibility, [2]Hematology and cellular therapy, University Medical Center, AMIENS, France

Background: MICA (MHC class I polypeptide-related sequence A) is a highly polymorphic gene closely linked to the HLA-B locus. It encodes a cell stress inducible glycoprotein, which mediates an activatory signal towards the NKG2D receptor expressed on NK-cells, CD8+ T-cells and NKT-cells. MICA polymorphisms have been shown to influence NKG2D signaling. Indeed, a methionine to valine change at position 129 in exon 3 categorized the MICA alleles into strong (MICA-129 met) and weak (MICA-129 val) binders of NKG2D receptor. 5 repetitions of GCT with 1 additional nucleotide insertion (G) in exon 5 designed the MICA A5.1 alleles with a premature stop codon. Moreover, NKG2D polymorphisms identified alleles associated with a low (NKC3 C/C and NKC4 C/C) or high cytotoxic activity (NKC3 G/G and NKC4 T/T).
Aims: In this study, we hypothesized that polymorphisms at the MICA and NKG2D loci are associated with adverse outcomes in HSCT.
Methods: Here, we evaluated whether recipient MICA and donor NKG2D polymorphisms (respectively MICA-129, MICA A5.1 and NKC3, NKC4) could influence the incidence of acute and chronic graft versus-host disease (GVH), overall survival (OS) and relapse free survival (RFS) on 124 patients undergoing allogenic hematopoietic stem cell transplantation using an HLA-matched donor (10/10).
Results: In an univariate model, recipient MICA A5.1 heterozygosity (p=0.030) and donor NKC4 C/C polymorphism (p=0.013) are associated with the increase of incidence of acute GVH (grade I to IV). Recipient MICA A5.1 heterozygosity is also associated with chronic GVH (p=0.04) while Recipient MICA-129 val/val tends to be a risk factor of chronic GVH without being statistically significant. These polymorphisms have no significant impact on OS and RFS in our study (median of follow up=15 months; range 0.2-49 months).
Summary/Conclusions: Our data suggest that a MICA or NKG2D low activity status can be related to an increase of acute GVH according to a mechanism that remains to be elucidated, maybe by a low cytotoxic activity on recipient dendritic cells.

E1538

STEM CELL TRANSPLANTATION WITH MYELOABLATIVE CONDITIONING USING TIMED SEQUENTIAL BUSULFAN IMPROVES OUTCOMES IN OLDER AML AND MDS PATIENTS

B. Oran[1,*], R. Saliba[1], S. Ahmed[1], A. Alousi[1], S. Ciurea[1], C. Hosing[1], I. Khouri[1], D. Marin[1], A. Olson[1], Q. Bashir[1], Y. Nieto[1], K. Rezvani[1], P. Kebriaei[1], B. Valdez[1], E. Shpall[1], B. Andersson[1], R. Champlin[1], U. Popat[1]
[1]Stem Cell Transplantation and Cellular Therapy, The University of Texas MDACC, Houston, United States

Background: We previously reported 6% 100 day NRM with a MA fludarabine (Flu) and busulfan (Bu) in older patients with a median age of 60 years. MA dose of Bu in this timed sequential (TS) regimen was administered over a longer period of time. To assess its impact on survival, we compared the outcomes of older patients treated with the TS Bu (TS cohort) or the RIC Flu/Bu regimen, which is used as standard (ST) for older patients at our center ST cohort.
Aims: To assess its impact on survival, we compared the outcomes of older patients treated with the TS Bu (TS cohort) and the reduced intensity conditioning with Flu/Bu regimen, which is used as standard (RIC cohort) for older patientsat our center.
Methods: Patients in the TS cohort received IV Bu 80mg/m^2/d on day -13 and -12 and Flu 40mg/m^2/d followed by IV Bu on day -6 to -3, dose adjusted to achieve a total Bu course AUC of 20,000µmol-min based on PK studies. Patients in the ST cohort received Flu 40mg/m^2 day followed by IV Bu daily for 4 days (day -6 to -3) dosed to achieve AUC of 16,000µmol-min. Patients with AML or MDS were eligible for the study if they had adequate organ function, had matched related or unrelated donor and were treated between Jan 2012 and Se.
Results: Patient characteristics including age, sex, disease status, cytogenetic risk group, donor type, graft source CMV status and comorbidity were similarly distributed between the two cohorts. Median age was 66 and 65 years in TS-MAC and RIC cohorts respectively. Overall survival (OS) and progression free survival(PFS) were significantly better in the TS -MAC cohort. This was due to a reduction in the disease progression without any increase in the TRM. After adjusting for other covariates, the multivariate analysis for PFS confirmed longer PFS with TS-MAC regimen (HR: 0.36; P=0.003). The benefit was mainly seen in patients with a comorbidity score ≤3.

Table 1.

	RIC cohort	TS-MAC cohort	RIC vs. TS-MAC	
	Estimate	Estimate	HR	p
2 year OS	31%	51%	0.6	0.01
2 year PFS	24%	45%	0.6	0.004
2 year progression	59%	34%	0.5	0.003
2 year TRM	12%	15%	1.3	0.5

Summary/Conclusions: The myeloablative timed sequential Bu regimen improves survival and appears promising in older patients with AML/MDS. The myeloablative timed sequential Bu regimen improves survival and appears promising in olderpatients with AML/MDS.

E1539

HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH DEPLETION OF TCR AB (+) IN CHILDREN: ERCIYES PEDIATRIC BMT CENTER

M. Karakukcu[1], E. Unal[1], E. Yilmaz[1], A. Ozcan[1], S. Kose[1], G. Ucan[1], T. Patiroglu[1,*]
[1]Department of Pediatrics, Division of Pediatric Hematology Oncology, Erciyes University, Faculty of Medicine, Kayseri, Turkey

Background: Recently, haploidentical hematopoietic stem cell transplantation (HSCT) posses an alternative option for patients without a suitable donor. Erciyes Pediatric BMT Center is the first pediatric center for haploidentical HSCT with depletion of TcR αβ **(+)** in Turkey.
Aims: We would like to share our pediatric experience with a follow up period of more than four years.
Methods: All children who underwent haploidentical HSCT in our center from December 2012 to February 2017 were included in the study. Total 51 haploidentical HSCT in 44 children (17 relapsed/refractory AML, 9 relapsed/refractory ALL, 4 SAA, 4 HLH, 2 Fanconi aplastic anemia, 2 Griscelli syndrome, 1 JMML, and 5 SCID) were performed. Transplantation-related mortality (TRM) was 13.7%. The regimen included ATG, Fludarabine, Thiotepa, Melphalan. Mycophenolate mofetil (MMF) was given as GvHD prophylaxis if the graft contained>5 x10^4/kg TcR αβ **(+)**.
Results: The mean of collected CD34 cells were 18,60 (range 3,98-43,66) x 10^6/kg. The graft had a purity of 99.9% TCRαβ depletion with a median of 0,257 (range 0.003 to 1,47) x 10^5 TCRαβ cells. The median engraftment days for myeloid and platelet were both 12th day of HSCT (range 7 to 28, 9 to 33 day) respectively. Grade II skin GvHD was detected in 8 patients, and treated with steroids without any further complications. However grade III, and grade IV gastrointestinal GvHD were observed in three patients. Although the patients with gastrointestinal GvHD were treated with steroid, budenosid, cyclosporine, MSC; one patient did not respond and died. MMF was given as GvHD prophylaxis in 36 patients and 15 patients did not receive any immune suppressive drug. The mean day of discharge was 34th day of HSCT. The long term follow up including immunological reconstructions were performed in 18 patients. The analysis of the immune reconstitution of the patients transplanted in haploidentical HSCT group showed a rapid immune reconstitution for CD3+ T cells 732 (range 126-2432)/mm3; for CD4+ helper T cells 92 (range 1–419)/mm3; CD8+ T cytotoxic cells 310 (range 95-2235)/mm3 at 28th day of HSCT. Twenty nine patients are currently alive, with a median follow up of 22 months (range 1 to 49 months). Overall survival was 65,9% in these group.
Summary/Conclusions: Our primary results underline that haploidentical HSCT with depletion of TcR αβ (+) can be an option in experienced center in countries which unrelated donor programs are not satisfactory, as in Turkey. The availability of a haploidentical donor in most families is a potential advantage. Moreover probably more potent graft-versus tumor effect can be induced with haploidentical HSCT.

E1540

SECONDARY MYELODYSPLASTIC SYNDROME AND/OR ACUTE LEUKEMIA INCIDENCE AFTER AUTOLOGOUS TRANSPLANTATION FOR LYMPHOMA PATIENTS IS CONNECTED WITH DECREASE OF HEMATOPOIETIC RESERVE

M. Trněný[1,*], M. Trnkova[1], D. Pohlreich[1], B. Vackova[1], Z. Gasova[2], R. Pytlik[1], P. Blahovcova[1]
[1]Charles University General Hospital, [2]Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Secondary myelodysplastic syndrome and acute myelogenous leukemia (sMDS/AML) is one of the most important long term complication of high dose therapy (HDS) with autologous stem cell transplantation (ASCT). The factors usually described to be associated with sMDS/AML development are pretreatment, HDS itself, radiotherapy, age and recently the evidence of TP53 mutations (Wong, Nature 2015) or clonal hematopoiesis (Gibson, JCO 2016) before ASCT.
Aims: The aim of the study was to analyse the incidence and risk factors for sMDS/AML after HDT and ASCT for lymphoma.
Methods: Patients who underwent HDT with ASCT for lymphoma in one centre since 12/1993 till 7/2016 were analysed. Pretreatment characteristic, graft quality, engraftment characteristics were included into analysis. Patients were censored at the time of death or allogeneic stem cell transplant. Pearson, Kaplan Maier, log-rank and cox regression tests were used.
Results: Altogether 728 pts underwent ASCT for lymphoma in given time period. The cohort consists out of 77% B-NHL (n566), 6% T-NHL (n 43) and 16% HL (n 119), 58% were men, age median at the transplant was 49 years (18-71). The median of previous lines was 2 (1-9). The stem cell collection was performed after chemotherapy and G-CSF mobilization in most cases, 19 pts were mobilized by G-CSF only and bone marrow only was used in 4 pts. The target CD34 dose was 3x10^6/kg. The median number of apheresis was 2 (1-12). At the time of ASCT 90.6% of patients had chemosensitive disease (51.1% CR) and 9.4% were transplanted for chemoresistant disease. Tandem HDT and ASCT was used in 36 pts, BEAM was the most frequent HDT regimen (92.5%, 15 pts received ibritumomab tiuxetan and BEAM), the total body irradiation was used only in 4 pts, the rest of the patients received other chemotherapy regimens (CPB, thiotepa based, ICE and others). All pts except 4 received peripheral blood progenitor cells (PBPC) with median CD34 dose 8.6x10^6/kg (0.4-115.5). BM was used in 22 cases (in 18 together with PBPC). G-CSF was administered from day +7. Involved or extended field radiotherapy either during previous therapy or in the period after ASCT was used in 37.7% of pts. With median follow-up 7.2 years there were observed 19 cases of sMDS/AML. The cumulative sMDS/AML incidence was at 5, 10 and 15 years 2.7%, 4.0% and 5.3% (figure A) in all lymphoma pts, 3.3% at 5,10 and 15y in HL pts, and 2.6%, 4.3% and 6.3% in NHL pts (figure B). There was significantly increased sMDS/AML incidence in pts with ³3 previous lines (7.7% *vs* 1.9% at 5y, HR 3.9, p 0.005), in pt's group with chemoresistant disease (8.1% *vs* 2.3%, HR 3.5, p 0.05), in CD34+ dose<3.0x10^6/kg (14.3% *vs* 2.5% at 5y, HR 4.9, p 0.05), in BM reinfused group (13.7% *vs* 2.5% at 5y, HR 4.7, p 0.05), in patients with prolonged platelet engraftment above 20x10^9/l - ³15 days *vs* 11-14 days *vs* £10 days (5.4% *vs* 3.0% *vs* 0.9%, p 0.05). There was no difference between groups of NHL and HL, with and without radiotherapy, according to the apheresis number or neutrophil engraftment. In multivariate analysis in the whole cohort the independent risk factors were number of previous therapy lines, disease status at ASCT and the speed of platelet engraftment (p <0.05). For NHL only number of previous therapy lines (p<0.05), for HL number CD34+cell reinfused, use of BM as the progenitor cell source and disease status (p<0.05).

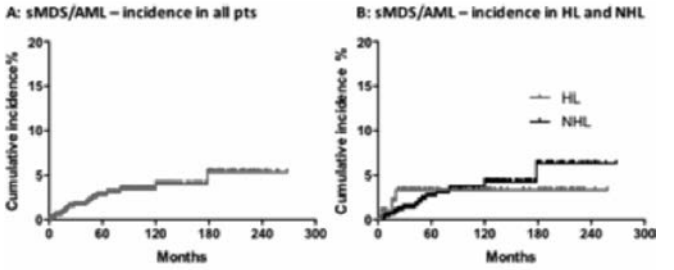

Figure 1.

Summary/Conclusions: The risk of sMDS/AML was 4.0% at 10y after ASCT and was connected with heavier pretreatment, which leads to the decrease of BM reserve, hematopoietic clonal development. The lower dose of CD34+ cell, the necessity to use BM progenitor cell and prolonged platelet engraftment could be considered as clinical markers of these biological processes.

E1541

USE OF DEFIBROTIDE TO TREAT TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY

M. Martinez-Muñoz[1,*], A. Lario[1], G. Bautista[1], J. Bueno[1], B. Navarro[1], A. De Laiglesia[1], J. Cabrera[1], R. Duarte[1]
[1]Hospital Universitario Puerta de Hierro Majadahonda (Madrid), Majadahonda, Spain

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is a severe early transplant complication which results from endothelial injury and it exhibits characteristics of an atypical hemolytic uremic syndrome. Beyond removal or treatment of precipitating factors and, more recently, treatment with eculizumab, TA-TMA remains a therapeutic challenge. Defibrotide, with marked protective effects on the endothelium and the potential to restore thrombotic-fibrinolytic homeostasis in small vessels, may be considered a therapeutic option for TA-TAM.
Aims: To analyze our center's experience in the treatment of TA-TMA with defibrotide.
Methods: We reviewed all cases of TA-TMA treated with defibrotide in our allogeneic transplant recipients between October 2008 and November 2016. All cases had non-inmune hemolytic anemia with high LDH, low haptoglobin and negative Coombs test, >2 schistocytes per high-power field and thrombocytopenia (<50x10^9/L or <50% of normal baseline). Cases without signs of renal or neurological dysfunction were classified as probable TA-TMA [Uderzo C, 2014].
Results: We identified 17 TA-TMA episodes treated with defibrotide in 16 allogeneic transplant recipients: 9 men; median age 38 years old (16-57); 10 single-cord blood plus third-party donor cells [Bautista G, 2009], 3 HLA-identical siblings and 3 unrelated donors; 13 myeloablative conditioning regimen, 10 with total body irradiation (Table 1). Concomitant risk factors at the time of TA-TMA onset were: calcineurin inhibitor treatment in all cases (13 cyclosporin, 4 tacrolimus), acute GVHD grade ≥II/IV in 8 cases, 3 CMV reactivations and 3 severe fungal (1 pulmonary aspergillosis, 1 *Scedosporium Prolificans* septicemia) or bacterial (1 *E Coli* sepsis) infections. Median onset of TA-TAM was on day +43 after transplant (2-556); 11 cases of early onset (<2 months) and 6 of late onset. Nine episodes were probable TA-TMA without organ dysfunction, 8 had renal failure and 2 presented with concomitant diffuse alveolar hemorrhage. First line replacement of calcineurin-inhibitors for basiliximab or other

drugs for GVHD was performed in all cases. Defibrotide was subsequently administered as monotherapy in 5 cases, in combination with rituximab and/or plasma exchange in 7, and with other agents in 5 others (2 vincristine; 1 eculizumab; 1 bevacizumab; 1 mesenchymal stromal cells). Complete resolution of TA-TMA (CR) was achieved in 11 episodes (65%), and associated with a reduced all-cause mortality: 18% of CR cases (2/11: 1 multilobar pneumonia and 1 toxic encephalopathy) *versus* 83% of cases without CR (5/6, *P*=0.035; 1 TA-TAM-related diffuse alveolar hemorrhage, 1 lymphocytic encephalitis and 3 severe infections). TA-TMA cases triggered by severe infections had early (days 4, 11 and 15 after onset) and higher mortality rates (3/3, 100% *vs* 4/14, 29%; *P*=0.023). Rates of CR were higher in cases of probable TA-TAM without renal failure (8/9, 89% *vs* 3/8, 38%; *P*=0.027) and early-onset TA-TAM (9/11, 82% *vs* 2/6, 33%; *P*=0.046).

Table 1.

Table 1. TA-TMA episodes overall and per response to defibrotide treatment.

	All TMA episodes	Resolved TMA episodes	Unresolved TMA episodes
Number of episodes	17	11	6
Age at HCT (years)	38 (16-57)	40 (16-57)	33 (21-48)
Sex			
- Male	9	7	2
- Female	8	5	3
Indication for HCT			
- ALL	8	5	3
- AML/MDS	4	3	1
- Lymphoma	3	2	1
- Multiple Myeloma	1	1	0
- Aplastic Anemia	1	1	0
Potential Risk Factors			
- GVHD	8	6	2
- CMV reactivation	3	2	1
- Infection	3	0	3
- CsA / Tacrolimus	13/4	9/3	4/1
- CB / SD / UD	11/3/3	8/1/3	3/2/0
- MAC / RIC	14 / 3	9 / 3	5 / 0
- MAC TBI	11	7	4
- MAC No TBI	3	2	1
TMA by organ dysfunction			
- Probable TMA	9	8	1
- With organ dysfunction	8	4	4
Day of TMA onset	+43 (2-556)	+36 (2-308)	+117 (3-556)
- Early onset (<+60)	11	10	1
- Late onset (>+60)	6	2	4
TMA treatment			
- DF monotherapy	5	3	2
- DF in combination	12	9	3
All cause mortality	7	2	5

Abbreviations: ALL: acute lymphoblastic leukemia; AML: acute myeloid leukemia; CB: Cord Blood; CMV: cytomegalovirus; CsA: cyclosporin A; DF: defibrotide; GVHD: graft-versus-host disease; HCT: hematopoietic cell transplant; MAC: Myeloablative Conditioning; RIC: reduced intensity conditioning; SD: Matched Sibling Donor; TA-TAM: transplant-associated thrombotic microangiopathy; TBI: Total Body Irradiation; UD: Matched Unrelated Donor;

Summary/Conclusions: TA-TMA is a severe endothelial dysfunction syndrome for which, beyond the complement inhibitor eculizumab, treatment is not well established. Defibrotide has proven to be safe and effective in sinusoidal obstruction syndrome. Here, we provide encouraging evidence suggesting that defibrotide, as monotherapy or in combination with other agents, may also have a role in the treatment of TA-TMA. Our data show complete resolution of TA-TMA in two thirds of cases, and even higher in those with early treatment and early onset forms of the disease. Validation of single-center experience in prospective controlled studies should be warranted.

E1542

PRE-TRANSPLANT COMORBIDITY AS AN OUTCOME PREDICTOR IN HEMATOPOIETIC CELL TRANSPLANTATION FOR SEVERE APLASTIC ANEMIA

S.-N. Lim[1,*]
[1]Internal Medicine, Haeundae Paik Hospital, Busan, Korea, Republic Of

Background: In the context of allogeneic hematopoietic cell transplantation (allo-HSCT), comorbidites are an important risk factor. Use of the hematopoietic cell transplantation-specific comordigity index (HSCT-CI), which was modeled to effectively capture comorbidity and predict post-transplant outcomes. HSCT-CI had been evaluated in a chort of patients with a variety of hamtologic malignancies. However, it was not validated in a cohort of adult patients with non-hematologic malignancies.
Aims: We performed multi-center retrospective study to validate the prognostic impact of HSCT-CI on transplant outcomes in a cohort of aplastic anemia patients undergoing allo-HSCT.
Methods: In this study, we applied the HCT-CI to 140 patients with severe aplastic anemia (SAA) who underwent allogeneic HCT at the Asan Medical Center, Seoul, and Haeundae Paik Hospital, Busan, Korea between April 1995 and March 2013. Required data were retrieved from Asan medical center and Haeundae Paik Hospital BMT Registry Database. We stratified the patients based on comorbidities, as assessed by HCT-CI. Post-transplant outcomes were evaluated in terms of overall survival (OS) and event-free survival (EFS). Event was defined as graft failure including primary and secondary, relapse, donor lymphocyte infusion, and death.
Results: The median age of including patients was 31 year-old (range, 31-61 year-old) and male was 81 patients (58%). HCT-CI score was 0 in 92 patients (65.0%), 1-2 in 34 (24.3%), and ≥3 in 14 (10.2%). The most prevalent comorbidity captured by the HCT-CI was infection (n=20, 14%) followed by moderate/severe hepatic comorbidity (n=10, 7%). During a median surviving post-HCT follow-up period of 45.5 months (range, 4.1-178.4 months), 32 patients (24%) died and 20 (14%) experienced primary or secondary graft failure. The 10-year probability of OS and EFS was 73.4% and 68.3%, respectively. OS and EFS was significantly different according to HCT-CI score; the OS for HCT-CI 0, 1-2, and ≥3 at 4 years was 84.1%, 68.6%, and 60.6%, respectively (*P*=0.007). The EFS for HCT-CI 0, 1-2, and ≥3 at 4 years was 76.5%, 60.0%, and 56.3%, respectively (*P*=0.019). Multivariate analysis after adjustment for other variables demonstrated that higher HCT-CI score were associated with increased OS and EFS as judged by increasing hazard ratio compared to patients with HCT-CI score of 0 (Table 1).

Table 1.

Prognostic factors		EFS		OS	
		HR (95% CI)	P	HR (95% CI)	P
HCT-CI scores (compared to low risk)	Intermediate risk	2.764 (1.388-5.486)	0.004	3.369 (1.629-7.422)	0.003
	High risk	2.923 (1.090-7.837)	0.033	3.418 (1.102-10.582)	0.033
Age (years)	<40 vs ≥40	1.995 (1.014-3.917)	0.046	2.052 (1.194-6.692)	0.006
Duration from Dx to HCT	≤8 vs >8 (month)	2.715 (1.098-6.710)	0.031	1.928 (0.648-5.748)	0.238
HLA matching (serum)	Full matched vs one or more mismatched	2.154 (0.853-5.439)	0.105	2.905 (1.086-7.778)	0.034

Table 1. Multivariate analysis of prognostic factors for event free survival (EFS) and overall survival (OS) among patients with severe aplastic anemia with allogeneic hematopoietic cell transplantation (HCT). CsA: cyclosporin, Dx: diagnosis, HLA: human leukocyte antigen, HCT-CI: hematopoietic cell transplantation comorbidity index, IST: immune suppressive treatment

Summary/Conclusions: In conclusion, our data indicate that the presence of pre-transplant comorgicity assessed by HSCT-CI may predict worse outcomes after allo-HSCT in severe aplastic anemia.

E1543

EFFICACY AND SAFETY OF FILGRASTIM BIOSIMILAR COMPARED TO FILGRASTIM ORIGINATOR IN THE STEM CELL MOBILIZATION AND HEMATOPOIETIC ENGRAFTMENT IN PATIENTS UNDERGOING STEM CELL TRANSPLANTATION

M. López-Parra[1,*], M. Baile[1], J. Dávila[1], J.C. Caballero[1], Á. Veiga[1], N. Arratibel[1], F. López-Cadenas[1], L. García-Martín[1], M. Salinero[1], N.C. Gutiérrez[1], O. López-Villar[1], M.D. Caballero[1], R. García-Sanz[1]
[1]Hematology, University Hospital of Salamanca, Salamanca, Spain

Background: Neupogen® is the original Filgrastim used for peripheral blood stem cell mobilization (PBSC) in patients and donors selected for stem cell transplantation (SCT). Nivestim® is a Filgrastim biosimilar approved for the same indications as Neupogen®.
Aims: To evaluate the efficacy and safety of Nivestim® in the PBSC mobilization for harvesting and hematopoietic SCT.
Methods: Retrospective, controlled, observational study conducted at the University Hospital of Salamanca (Spain) between JAN08 and DEC15.
Results: The study included 365 patients candidates for ASCT and 217 healthy sibling donors for Allo-SCT who underwent PBSCs mobilization. Neupogen® (Amgen Europe BV, Breda, NL) was administered for mobilization at standard doses until SEP2012, while Nivestim® (Hospira, Maidenhead, UK) was used from that date. Among PATIENTS, 145 were mobilized with Nivestim® and 220 the originator Neupogen®. Patient characteristics between groups were similar, although lenalidomide was more frequently used in the Nivestim® group, as it corresponds to more recent transplants. The mean number of $CD34^+$ cells/µl in the peripheral blood after 4 days of mobilization treatment was not significantly different (Neupogen®73.2, SD=113.0; Nivestim® 94.5, SD=166; p=0.15), but the mean of the total $CD34^+$ collected cells was 4.75, SD=4.41 in the Neupogen® and 6.35±6.42 in Nivestim® group (p=0.01), with a larger number of apheresis procedures needed in the Neupogen® group (1.39, SD=0.65 *vs* 1.24, SD=0.45; p=0.02). The mobilization failure rate was slightly higher with Nivestim® (22%) than with Neupogen®(13%, p=0.04), although it was attributed to a more frequent use of lenalidomide. Most patients underwent ASCT: 87% and 92% patients in the Neupogen® and biosimilar groups, respectively. There were no statistically significant differences in hematopoietic recovery and trans-

plant-related toxicity. The median hospitalization time (20, range 14-70 *vs* 20, range 14-53, p=0,72) and the consecutive number of re-admissions after discharge (27% *vs* 35% p=0,35) were also similar between Neupogen® and Nivestim® groups. In the group of HEALTHY DONORS, 95 were mobilized with Neupogen® and 122 with Nivestim®. Donor characteristics were equivalent between groups, and no severe adverse events were registered in any of them. Mean of $CD34^+$ cells collected/kg of recipient body weight was $7.62x10^6$, SD=$3.45x10^6$ for Nivestim® *vs* $6.26 x10^6$, SD=$2.71x10^6$ Neupogen®(p=0.002), but the minimal target cell dose ($2x10^6$/kg) was collected in all donors. 8.5% of donors mobilized with Nivestim® failed to achieve the optimal cell dose ($4x10^6$/kg) compared with 13% in the Neupogen® group (p=0.25). All recipients were successfully transplanted. All donors for haploidentical transplants (N=25) were mobilized with Nivestim®; none with Neupogen®. There were no other transplant differences. Platelet and neutrophil engraftment were comparable between the two groups, as well as transfusion requirements and infectious complications after transplant. The incidence of grade 1 to 4 acute graft-versus-host disease was not different (Nivestim®65.5% *vs* Neupogen® 67.7%; p=0,7). The hospitalization period was similar in Neupogen® and Nivestim® groups, (30 days, range 16-102; 30 days, 16-136, respectively).

Table 1.

Characteristics and main results comparison in patients who underwent autologous stem cell transplantation

Results	Nivestim® (N=145)	Neupogen® (N=230)	P value
CD34+cells/μL in peripheral blood, median (range)	35.07 (1-1151)	43.96 (1.5-1019)	0.18

Summary/Conclusions: Although prospective data are still required, our study supports that the use of the Filgrastim biosimilar Nivestim® has a similar efficacy and safety as mobilization agent compared with the originator Neupogen®.

E1544

PERIPHERAL BLOOD STEM CELL DONATION IN OLDER SIBLING DONORS: IS IT SAFE?

K. Balassa[1,*], A. Peniket[1], R. Danby[1], R. Pawson[1]
[1]Department of Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: The introduction of reduced intensity conditioning regimens has led to an increase in allogeneic haematopoietic stem cell transplantation (HSCT) in older patients with a consequent increase in age of family members who are asked to donate HSCs for them. Such donors are expected to have more co-morbidities than younger donors and careful assessment of their suitability to donate is required.
Aims: Our aim was to assess the frequency and nature of issues concerning the eligibility of related peripheral blood stem cell donors seen at Churchill Hospital, Oxford between 2012 and 2016. We wished to examine the influence of age and the nature of any extra interventions required to establish donor suitability.
Methods: For clinical data collection donors' notes were reviewed and analysed retrospectively. At our centre the same template was used in all cases for sibling donor selection and screening.
Results: During the study period 90 related donors were screened, of whom 1 declined to proceed because of his concerns regarding G-CSF safety, 2 were excluded due to pre-existing medical conditions and 2 were defined medically ineligible during work-up, and finally 85 donors donated PBSCs to their relatives (36% of allogeneic HSCT performed at our centre). The median donor age was 51 years (range 25-71, n=17 over 60). Nearly half of the donors (44%) took regular medications. Two thirds (67%) suffered from at least one significant comorbidity (25% hypertension, 24% back problems, 16% asthma, 9% cardiovascular conditions, 9% diabetes mellitus, 8% autoimmune disease). The presence of comorbidities was significantly associated with age (p=0.033). 59% travelled abroad, of whom 14% visited a malarial area within a year of donation. Based on donors' history or examination findings, 47% needed extra blood tests on top of the mandatory tests before the clearance, including malaria (31%) and haemoglobinopathy screening (13%). 6% underwent specific haematology investigations *e.g.* BMA, molecular studies. Additional imaging studies were performed in 13%. In 16% specialist opinion was sought from other specialties with concerns regarding donor fitness or safety. 13 out of 85 cases were handled as planned deviation from our standard eligibility criteria. Two donors needed central venous access for stem cell collection. The collected median CD34+ dose was $5.73x10^6$/kg (range 1.76-22.45). Collection was completed in one day in 54%, in two in 44% and in three in 2%. Male (p=0.017) and younger donors (p=0.041) were more likely to achieve stem cell yield in one day collection. The stem cell dose was higher for collections being successful in one day (median 6.5 *vs* 5.03, p<0.001). Citrate related toxicity was the most common complication of the apheresis procedure (52%). The only documented serious complication affected a 69-year old donor who was hospitalized on 3rd day of G-CSF treatment with chest and abdominal pain and troponin rise, but investigations excluded acute coronary syndrome or other significant acute pathology and she managed to donate successfully with no further issues.
Summary/Conclusions: Peripheral blood stem cell collection seems to be safe among sibling donors, who are significantly older than unrelated donors. With careful assessment and planning even individuals with significant co-morbidities can donate successfully. The demographic trend and its implications should be considered when planning resources in HSCT programmes.

E1545

LONG-TERM RESULTS OF DONOR LYMPHOCYTE INFUSIONS IN RELAPSED AND MIXED CHIMERISM PATIENTS AFTER ALLOGENEIC STEM CELLS TRANSPLANTATION

O. Koroleva[1,*], E. Parovichnikova[1], L. Mendeleeva[1], L. Kuzmina[1], M. Drokov[1], V. Vasilyeva[1], Z. Konova[1], E. Mikhalcova [1], D. Dubnyak[1], N. Popova[1], V. Savchenko[1]
[1]BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a potentially curative treatment for patients with hematological malignancies. However, relapse remains the major cause of treatment failure after allo-HSCT. Mixed chimerism (MC) can induce immunologic tolerance and lead to relapse. One of the most effective approaches to treat these patients is donor lymphocyte infusion (DLI) with or without chemotherapy.
Aims: To analyze long-term results DLI in early posttransplant MC and in relapsed patients after allo-HSCT.
Methods: The study included 61 patients of in whom DLI with interleukin 2 (IL-2) was administered at the National research center for Hematology from 2011 till 2016. DLI with IL-2 was administered for patients with MC, more than 10-15% recipient DNA (n=26). A median age was 33 years old (19-54 years). Eight were males, 20 – females. There were AML (n=17), ALL (n=4), MDS (n=2), CML/MPN (n=3). Before allo-HSCT complete remission had in 20 patients and 6 had relapse/progression disease. Patients received allo-HSCT from related (n=20) or unrelated (n=6) donor. The intensity of conditioning was mainly reduced intensity (n=15) rather than myeloablative conditioning (n=11). Bone marrow (BM) as a graft source was used in 20, PBSC – 6. DLI was started at low dose $1*10^7$CD 3+ per kg. Every following dose of infusion CD 3+ increased until $5*10^7$CD 3+ per kg. Number of infusions depended on achievement 100% donor chimerism. Thirty five patients with relapse after allo-HSCT (AML, n=27, ALL, n=5, MDS, n=2, CML, n=1) were administered DLI with IL-2. Number DLI was 1 or 5 in different causes. Complete remission before allo-HSCT had in 25 patients and 10 had relapse/progression disease. 33 patients received chemotherapy and after chemotherapy on 7 days DLI was using an escalating dose following infusions. Two patients received DLI with IL-2 without chemotherapy. A median age was 33 years old (18-60 years). 14 were males, 21 - females. Stem cell source was BM and (PBSC) in 22 and 13 of the cases, respectively. Patients were transplanted from related (n=17) and from an unrelated donor (n=18). Condition regimen was MAC (n=7), RIC (n=28). Bone marrow as a graft source was used in 22, PBSC – 13.

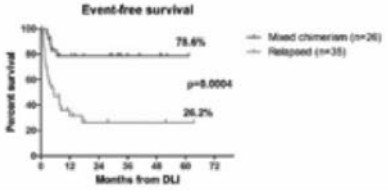

Figure 1.

Results: A median follow up was 5 months (0,3-63). A median time between allo-HCST and DLI was 3 months (1,5-64). 100% donor chimerism was achieved in 17 patients with MC from 26 (65%). A median number of infusions

was 2 (1-5). There were 5 (19%) graft failures. Acute GVHD appeared in 8 (32%), all of them as grade 3; chronic GVHD occurred in 7 (27%). Patients with a MC had better overall survival 77,6% than patients with relapse after allo-HSCT (22%). Remission was achieved in 16 (48%) patients with relapses. However, 5 patients relapsed again. Acute GVHD was developed in 8 cases (22%). Nineteen patients died from relapse and 1 patient died from aGVHD in remission. Event free survival in patients with MC and in patients with relapses was 78,6% and 26,2%, respectively.
Summary/Conclusions: The prognosis of hematological malignancies is poor if relapse is established after allo-HSCT. DLI protocol as preventive therapy must be created for improving long-term results in high risk patients. "Prevention is better than cure."

E1546

MEMORY T CELLS DONOR LYMPHOCYTE INFUSIONS AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION AS A SAFE PROCEDURE TO IMPROVE T-CELL RECONSTITUTION

S. Cortez [1,*], R. De Paz[1], M. Gasior[1], A. Martínez[1], Y. Mozo[2], B. Rosich[2], J. Valentin[1], A. Sastre[2], A. Pérez [2]
[1]Hematology, [2]Pediatric Hematology-Oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Hematopoietic stem cell transplantation (HSCT) is a potential curative treatment for patients with hematologic malignant diseases. Haploidentical transplantation with extensive *ex vivo* T cell depletion of the graft, has demonstrated to prevent graft *versus* host disease (GVHD), but the major disadvantage has been the development of graft failure, relapse and infections due to delayed immune reconstitution. A selective T cell depletion method that removes T naïve cells that express CD45RA+ in haploidentical donor lymphocytes, which are responsible for GVHD, as well as preservation of memory T cells CD45RO, is a novel therapy that may provide functional T cells with anti-infection, anti-leukemia and anti-rejection properties.
Aims: We describe the outcome of CD45RA+ cell depletion of donor lymphocytes infusions, in patients with hematologic diseases with mixed chimerism, severe infections and high risk of relapse after hematopoietic stem cell transplantation.
Methods: Patients with hematologic diseases with poor prognosis who lacked an HLA matched donor were included. The recipients received a CD45RA-depleted haploidentical transplantation, on day 0 they received a first graft with a median CD34+ cell dose of $6.44x10^6$/Kg (range $5x10^6$/Kg-$9x10^6$/Kg), on day +1 they received a CD45RA-depleted graft. After transplantation studies of chimerism, quantification of lymphocyte subsets as well as control for viral infections were made to all patients.
Results: We present the results of six patients with a median age of 11 years (range 4 to 15 years), diagnosis included B-Cell acute lymphoblastic leukemia (n=2), T cell acute lymphoblastic leukemia (n=1), acute myeloblastic leukemia (n=2), aplastic anemia (n=1), these patients received a selective CD45RA-depleted haploidentical transplantation. During the follow up after HSCT, three patients had persistent lymphopenia, four patients developed infections caused by CMV, norovirus, HHV-6, BK virus and toxoplasma, one patient had increasing levels of mixed chimerism and one had graft failure. These patients were treated with infusions of 16 aliquots of cryopreserved CD45RO+ haploidentical donor lymphocytes, the CD45RA+ cells depletion was made using the cliniMACS system. The median dose of CD45RO+ cells was $1,02x10^7$/Kg, starting at a dose of $1x10e^5$/Kg until a maximal dose of $2x10e^8$/Kg, infused every 21 days. The CD45RA+ cell dose was a median of $0.0045x10^3$/Kg (range: 0-$1,6x10^3$/Kg). All the procedures were well tolerated, neither adverse events nor GVHD were noticed. After the DLI, a progressive increase in T cells count were observed.
Summary/Conclusions: In our experience DLI enriched for CD45RO+ memory T Cell is a promising and safe strategy for patients with severe viral infections and risk of relapse after haploidentical HSCT, these cells has demonstrated to trigger the CD4 and CD8 T-cell reconstitution, which will help reduce risk infection with a low risk of GVHD. However further studies are needed in order to support this therapy.

E1547

FLAG REGIMEN WITH IDARUBICINE AS CYTOREDUCTION THERAPY BEFORE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH REFRACTORY ACUTE MYELOID LEUKEMIA

L. Wang[1,*], R. Devillier[2], X. Fan[1], W. Tang[1], S. Harbi[2], N. Vey[2], J. Hu[1], D. Blaise[2]
[1]Blood and marrow transplantation center, Department of Hematology, Rui Jin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Unité Transplantation et de Thérapie Cellulaire, Département d'Hématologie, Institut Paoli-Calmettes, Marseille, France

Background: Allogeneic hematopoietic stem cell transplantation (Allo-HSCT) is the only curative option for patients with refractory acute myeloid leukemia (AML). However, allo-HSCT with standard conditioning regimen could merely achieve a long-term survival of 20% and the key problem is the high relapse rate even after transplantation.
Aims: We have evaluated the safety and efficacy of new conditioning regimen with sequential intensive chemotherapy (FLAG-IDA) followed by conditioning of Flu-Bu(3).
Methods: The study was designed and developed in two separate transplantation centers in Rui Jin Hospital (RJH, Shanghai) and Institut Paoli-Calmettes (IPC, Marseille) respectively. A total of 47 refractory AML patients with median bone marrow blast of 35% (1~90%) and median age at 42y (16~62) were enrolled. Thirteen patients received transplantation with mobilized peripheral blood stem cells (PBSC) from HLA-matched sibling donor while 18 and 16 with matched unrelated or haplo-identical donors. All patients received FLAG + 3-days idarubicine ($12mg/m^2$ in RJH or $10mg/m^2$ in IPC) and then received Fludarabine (5 days) with IV Busulfan (3-days) with a 7-day interval. The GVHD prophylaxis regimens were CsA+MMF±ATG (RJH) or post-cyclophosphamide (IPC).
Results: With a median follow-up of 8 months (1~70m), a total of 14 patients relapsed with a median time of relapse at 4.8 months (2.1~18.1) and most of them (11/14) relapsed within first 6 months after transplantation. A total of 24 patients died due to relapse (n=12) or non-relapsed mortality (NRM, n=12). The estimated 3-year relapse rate (RR) and NRM were 42.0±9.2% and 25.9±6.5% respectively. The estimated 3-year OS and DFS were 43.6±7.8% and 42.2±7.8%. In the primary multivariate analysis (including age, cycles of pre-transplantation chemotherapy, bone marrow blasts, cytogenetics and treatment center), only bone marrow blast ≥35% and age over 40 were associated with disease-free survival and relapse respectively while there was no significant difference between RJH and IPC in terms of transplantation outcome in uni- and multivariate analysis.
Summary/Conclusions: Our primary data demonstrated a promising outcome with FLAG-IDA chemotherapy as debulking therapy sequential with Flu-Bu3 conditioning regimen in patients with refractory AML and clinical trial with larger patients cohort is warranted.

E1548

STUTTER PCR PRODUCTS MAY NOT INTERFERE WITH STR BASED CHIMERISM MONITORING AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION

N. Kostritsa[1,*], N. Risinskaya[2], E. Parovichnikova[3], A. Sudarikov[2]
[1]School of Medicine, Lomonosov Moscow State University, [2]Department of Molecular Hematology, [3]2Department of Hematological Oncology and BMT, National Hematology Research Center, Moscow, Russian Federation

Background: Chimerism analysis is one of the main methods to monitor the bone marrow engraftment or disease relapse after allogeneic bone marrow transplantation. Routine test is based on differences in the length of short tandem repeats (STR) from the donor and the recipient. However, chimerism estimation is complicated by stutter PCR peaks appearing due to irregular DNA polymerase activity. Generally, these sequences are 4 nucleotides shorter than a specific marker and may concur with a specific sequence of recipient's DNA hindering chimerism estimation based on that locus. This problem seems to be especially serious in case of a sex-matched sibling BMT when most of the alleles for donor and recipient are the same. One may suggest to limit the use of these markers for the cases with stutter-bands comparable with donor allele peak height. Thereby, the absence of "stutter-peaks free" markers hinders mixed chimerism estimation at the point of low recipient hematopoiesis output.
Aims: To identify the contribution of stutter-bands to the total amount of PCR-product and to derive universal formulas for the chimerism calculation excluding stutter percentage.

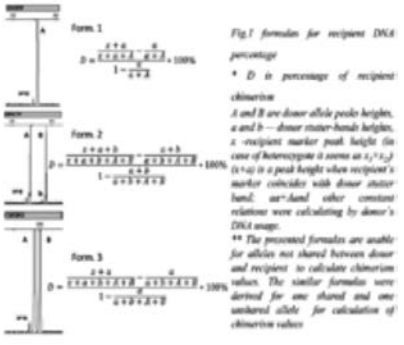

Figure 1.

Methods: Genomic DNAs of donors and patients were isolated from bone marrow samples. Chimerism was assessed by the STR-PCR analysis (polymerase chain reaction with a panel of primers for loci of short tandem repeats) with COrDIS Plus multiplex kit for amplification of 19 polymorphic STR-markers and amelogenin loci. The fragment analysis was performed on a 3130 Genetic Analyzer. The data processing was accomplished using GeneMapper v.4-0 software. Informative loci were chosen beforehand comparing pretransplant

patient DNA and donor DNA. The percentage of donor chimerism as well as stutter percentage was calculated using standard formula.
Results: Fifty transplant cases with stutter peaks were evaluated: 18 homozygous; 15 heterozygous with both alleles showing detectable stutter; 17 heterozygous with one stutter visible only. Stutter percentage and standard deviation were calculated in each case for donor DNA sample and for four bone marrow DNA samples from recipient with established complete donor chimerism taken during the time. It was found that the contribution of the stutter-peaks into the total amount of product ranges from 1.2% to 11% (SD was no more than 1.5% for each locus) for markers with appreciable stutter-bands and seems to be locus-specific constant for each patient. Assuming the stutter percentage as a locus- and patient-specific constant (for the same PCR conditions) we derived a formulae for recipient DNA percentage: *Actual recipient's%=(apparent rec./total DNA ratio - stutter/total DNA ratio):(1-stutter/total DNA ratio)*100%* (special formulas for hetero- and homozygous on fig. 1). To test these formulae the panel of DNA samples with mixed chimerism from 50 to 97% estimated by independent "stutter free" assay was used. The results of chimerism estimation based on "stutter-complicated" markers (using proposed formulae) conventional "stutter-free" markers appeared to be the same (SD<1%).
Summary/Conclusions: The use of formulae described may circumvent the absence of the "stutter-free" informative markers for mixed chimerism estimation.

E1549

INTRODUCING PLERIXAFOR TO IMPROVE MOBILIZATION IN MULTIPLE MYELOMA PATIENTS WHO BEHAVE AS POOR-MOBILIZERS IS COST-EFFECTIVE CONSIDERING THE WHOLE MOBILIZATION AND TRANSPLANT PROCEDURE

C. Chabannon[1,*], A.-G. Le Corroller-Soriano[2], R. Touzani[2], A.-M. Stoppa[3], C. Lemarie[1], M. Debals-Gontier[2], B. Calmels[1], R. Bouabdallah[3], A. Granata[3]
[1]Centre de Therapie Cellulaire. Departement de Biologie du Cancer, Institut Paoli-Calmettes, [2]SESSTIM, Inserm, [3]Departement d'Oncohematologie, Institut Paoli-Calmettes, Marseille, France

Background: Plerixafor, a CXCR4-antagonist, is efficient to improve CD34$^+$ cell mobilization and collection in candidates for autologous transplantation who behave as poor-mobilizers. The cost of the drug is however of concern. Published medico-economics studies were mostly conducted in the US, and few including detailed and comprehensive micro-costing of the collection and transplantation process; conclusions may thus not apply to European countries where cost structures are different.
Aims: To compare costs and effectiveness of plerixafor-free and plerixafor-replete management strategies for multiple myeloma patients who behaved as poor-mobilizers after adequate administration of a standard rhG-CSF mobilization regimen.
Methods: Sixty patients diagnosed with multiple myeloma were consecutively identified during years 2009-2011, immediately before and after EMA granted marketing authorization for plerixafor. Poor-mobilizers were defined as having circulating CD34+ cell counts below 20/µL. Plerixafor was introduced or not as a result of the attending physician's decision, reflecting progressive changes in medical practices over this transitional period. The historical and study groups were matched over four criteria: disease stage at diagnosis, age, gender and number of chemotherapy treatments received before mobilization. Two cost-effectiveness analyses (CEA) were conducted; the primary CEA looked at the criterion "collecting at least $2x10^6$ CD34+ cells"; a secondary CEA looked at the criterion "successful autologous transplant administered". Detailed micro-costing evaluations (2015 figures) did not or did include transplantation costs for the first and second CEA respectively.
Results: The two groups were similar in terms of age, sex distribution, disease characteristics or previous treatments. 27/30 and 26/30 patients proceeded to high-dose melphalan and autologous transplantation in the study and historical groups, respectively. There was a trend to a higher number of collected CD34$^+$cells in the control group; however, the proportion of patients who met the minimal target number of $2x10^6$ collected CD34$^+$ cells/kg was identical (28/30).Length of hospitalization, times to neutrophil and platelet recoveries, numbers of PRBC and platelet transfusions were identical in the two groups. Mobilization and collection costs per patients were more important in the plerixafor group that in the historical group (8.757 *vs* 5.460 €, p<0.0001), and proportionally higher in patients who received plerixafor as part of a remobilization treatment rather than pre-emptively (10.401 *vs* 8.162€ respectively). The main CEA concluded to a 3.237€ increase in costs for the same number of patients achieving a minimal target number of $2x10^6$ collected CD34$^+$ cells/kg. The second CEA found a decrease in the cost of transplant, with 12.724€ in the study group *vs* 13.634€ in the historical group (NS). In total, the 2.035€ increase for the complete procedure cost (22.866€ per successfully autografted patient in the study group *vs* 20.831€ in the historical group) was not statistically different.
Summary/Conclusions: Cost-effectiveness arguments should not been used against the administration of plerixafor in multiple myeloma patients in the European context. Future prospective researches looking at patients reported outcome criteria and labour organization in apheresis facilities are needed.

This work was supported by a grant from SANOFI S.A.

PERIPHERAL BLOOD STEM CELL (PBSC) HAPLOIDENTICAL TRANSPLANTATION *VERSUS* MISMATCHED UNRELATED DONOR TRANSPLANTATION: A SINGLE UK CENTRE EXPERIENCE

J. O'Sullivan[1,*], K. Parmesar[2], D. McLornan[2,3], D. L. Hugues[2], V. Potter[4], M. Streetly[1,4], M. Gallagher[4], I. Walker[4], M. Kazmi[1,2], A. Kulasekararaj[4], J. Marsh[4], G. Mufti[4], T. Pagliuca[4], K. Raj[2,3]
[1]Haematology, Guy's and St. Thomas' NHS Foundation Trust, [2]Haematology, King's College Hospital NHS Foundation Trust, [3]Haematology, Guy's and St. Thomas' NHS Foundation Trust, [4]Haematology, King's College Hospital NHS Foundation Trust, London, United Kingdom

Background: Haploidentical (Haplo) and mismatched unrelated donor transplantation (MMUD) are potential alternatives for those without a fully matched available donor. Recent collaborative and single centre studies suggest that haploidentical donor outcomes are comparable to unrelated donor outcomes in the T cell-replete setting.
Aims: In this single centre review, we aimed to compare outcomes of T cell-replete haploidentical allogeneic stem cell transplantation with mismatched unrelated donor allogeneic stem cell transplantation.
Methods: From January 2010 to December 2015, 38 patients underwent T cell-replete HLA-matched haploidentical transplantation with post transplantation cyclophosphamide given on days +3 and +4 given as graft *versus* host disease (GvHD) prophylaxis. These were retrospectively compared with 45 patients underwent single HLA-locus mismatched unrelated donor transplantation with alemtuzumab as GvHD prophylaxis. Data was censored at time of last contact in 2016. Analysis was performed using SPSS v.23.0 and R 3.3.2 statistical software.
Results: The median recipient age was similar in both groups; 51 (19-69) years in Haplo and 59 (28-74) years in MMUD transplants, p=0.012; 68.7% of all patients were male. Non-Caucasian ethnicity comprised 63.2% of Haplo *versus* (vs.) 15.6% of MMUD transplants, p<0.001. Myelodysplasia (MDS)/acute myeloid leukaemia (AML) was the commonest transplant indication in both groups (60.5% of Haplo and 93.6% of MMUD transplants). The disease risk index (DRI) in this subgroup was overall low/intermediate in 69.2% and high/very high in 26.2% (unknown in 4.6%). Reduced intensity conditioning was used in all but two Haplo (4.6%) and 4 MMUD transplants. Patients were followed up for a median of 544 days with a similar 2-year overall survival of 61.5% (95% confidence interval, CI, 52.4 – 69.3%) and 58.1% (95% CI 48.8-66%) and 3-year overall survival of 56.4% (95% CI 45.8 – 65.6%) and 48.9% (95% CI 41 – 56.2%) in Haplo and MMUD transplants respectively, p=0.67. Overall progression free survival (PFS) at 2 years was 53.3% (95% CI 44-61%) and 40.1% (95% CI 34-46%) in Haplo and MMUD transplants respectively, p=0.31. In those with MDS/AML, the 2-year progression-free survival was 64.2% (95% CI 49-75%) in Haplo *vs* 38.5% (95% CI 33-43%) in MMUD transplants, p=0.1. In Haplo and MMUD transplants, the 3-year cumulative incidences of non-relapse mortality were 25.5% (95% CI 12-41%) and 31.2% (95% CI 18-45%) respectively, p=0.61 and of relapse were 25.6% (95% CI 12-41%) and 34.8% (95% CI 20-49%) respectively, p=0.51. Median time to neutrophil engraftment was 18 and 12 days and for platelet engraftment 21 and 12 days in the Haplo and MMUD transplants respectively. Engraftment was successful in 89.4% (Haplo) and 95.5% (MMUD) of patients. The incidence of acute GVHD was 42.1% in Haplo and 35.6% in MMUD transplants but severe (grade 3/4) acute GvHD only occurred in 7.9% (Haplo) and 8.9% (MMUD). Chronic GvHD occurred in 15.8% of Haplo and 33.3% of MMUD transplants, p=0.067. Chronic GvHD did not impact overall or progression free survival in either transplant group.
Summary/Conclusions: T cell-replete haploidentical transplantation when compared with T cell-deplete mismatched unrelated donor transplantation showed high engraftment rates, low rates of severe acute and chronic GVHD and comparable overall survival, non-relapse mortality and relapse rates. We suggest that T cell-replete haploidentical transplantation is a safe and acceptable alternative when a matched unrelated donor is unavailable.

E1551

IMPACT OF ABO BLOOD GROUP INCOMPATIBILITY ON THE OUTCOME OF RECIPIENTS UNDERGOING ALLOGENIC TRASPLANTATION: EXPERIENCE IN OUR CENTER BETWEEN 2013 AND 2016

G.A. Méndez Navarro[1,*], G. Moreno Jiménez[1], F.J. López Jiménez[1], A. Jiménez Martín[1], S. López González[1]
[1]Servicio de Hematología y Hemoterapia, Hospital Universitario Ramón y Cajal. Madrid, Madrid, Spain

Background: ABO blood group compatibility is not an essential requirement or priority in the selection of the allogenic bone marrow donor, unlike what happens in solid organ transplant; thereby, up to 30-50% of allogeneic transpantation shows ABO incompatibility[1], but its clinical impact is controversial. It's accepted that it may provoke hemolitic reactions and delayed erytrhocyte engraftment. Nevertheless, its influence on leukocyte and platelet engraftment, graft-versus-host disease (GvHD), and overall survival is not fully elucidated yet[2].
Aims: To describe the experience in our center in allogenic transplantation with ABO mismatching and its relation with hemolytic events (HE), red blood cell

(RBC) recovery, neutrophil and platelet engraftment, pure red cell aplasia (PRCA), acute GvHD, relapse and overall survival (OS).
Methods: We retrospectively studied allogeneic transplants performed from January 1, 2013 to December 31, 2016. We collected the baseline variables reflected in Table 1 and analyzed the incidence of HE, neutrophil and platelet engraftments, RBC recovery, PRCA (defined as anemia with transfusional requirement and reticulocytes <1% in day +60 without other cytopenias), acute GvHD, relapse of the background disease and survival (at 6, 12 and 24 months) in the ABO compatible groups (ABOc) and in the incompatible (ABOi), the latest divided into major, minor and bidirectional disparity.
Results: A total of 133 transplants were included, with a mean follow-up time of 16.4 months. The median age was 52 years and there were 79 males and 54 females. Diagnoses were mainly AML (n=72), ALL (n=19) and NHL (n=11) (see Table 1). 60 received low intensity and 73 myeloablative regimens. They were HLA identical (n=44), unrelated donor (n=50), haploidentic (n=38) and cord (n=1) and, in most cases, hematopoietic progenitors were obtained from mobilized peripheral blood (90.2%). 44.3% (n=59) presented some type of ABOi: major (n=26), minor (n=25) and bidirectional (n=8). The product was processed in order to prevent hemolysis in only 7 cases (red cell depletion in 4 and deplasmatization in 3). There were 23 hemolytic (18 immediate and 5 delayed) -mostly mild- events, which appeared predominantly in patients with ABO-incompatibility (38.98%)- 50% in major disparity, 28% in minor and 37.5% in bidirectional- *vs* ABOc (2.7%) and this difference was statistically significant (p<0.0001). No differences were observed in the neutrophil graft between the ABOc group and the ABOi group, nor in the platelet engraftment; in contrast, we found a statistically significant effect on the time to erythrocyte recovery (mean: 49.94 days in ABOi *vs* 24.69 in ABOc; p=0.032). Only 6 cases of PRCA were documented (all in ABOi). The occurrence of acute GvHD did not differ significantly among the groups (52% in ABOc *vs* 53.5% in incompatibles) nor in its severity. We have not found differences either in the rate of relapse (24.6% *vs* 19.6%) nor in the survivals at 6, 12 or 24 months (66.1% *vs* 78.8%, 48.2 *vs* 47.2% and 38.4 *vs* 39.4%, respectively).

Table 1.

Table 1

	ABOc (n=74)	ABOi (Major) (n=26)	ABOi (bidirectional) (n=8)	ABOi (minor) (n= 25)
Gender (M: F)	45: 29	17:9	3:5	14:11
Age (median)	52	52	30	54
Background disease				
-AML/MSD	45	12	4	11
-ALL	9	4	2	4
-NHL	5	2	-	4
-HL	2	1	1	-

-Related HLA-identical	30	6	2	6
-Unrelated	20	11	4	15
-Haploidentical	24	9	2	4
Source (PB: BM: Cord)	69: 5:0	21: 5: 0	6: 1: 1	24: 1: 0
Intensity (MA: RIC)	40:34	15: 11	7: 1	11: 14
Product processation	0	3	3	1

** M=male, F=female; AML= acute myeloid leukemia, MSD: Myelodisplastic syndrome, ALL=acute lymphoblastic leukemia, NHL= non hodgkin lymphoma, MM= multiple myeloma, AA= aplastic anemia, PNH= paroxysmal nocturnal hemoglobinuria; PB= peripheral blood, BM= bone marrow; MA= myeloablative, RIC= reduced intensity conditioning.*

Summary/Conclusions: In our study ABO-mismatched transplants have shown a greater number of hemolytic events and red cell aplasia, as well as a greater delay in achieving erythrocye recovery. However, we have not found an association with delayed neutrophil and platelet recoveries, increased acute GvHD, relapse or worse OS in the ABO incompatible group, in keeping with most previous reports**, although the absence of effect might be as well be related to an insufficient study power due to low sample size.

LOW BLOOD CONCENTRATION OF TACROLIMUS CAN BE A RISK OF GRAFT FAILURE AFTER CORD BLOOD TRANSPLANTATION

A. Fujimoto[1,*], T. Ishikawa[1]
[1]Hematology, Kobe City Medical Center General Hospital, Kobe, Japan

Background: Cord blood transplantation (CBT) has recently emerged as an attractive alternative donor. However, graft failure still remains potential threats for morbidity and mortality.
Aims: Several biological mechanisms may contribute to graft failure. Immunological rejection of the graft is known as a major cause of graft failure. Graft failure may also be caused by septicemia, viral infections, drug toxicity and so on.These events have been frequently occurred just before engraftment, and we often experience fluctuation of blood levels of immunosuppressive drugs. Here, we analyzed an association between blood levels of Tacrolimus (Tac) before neutrophil engraftment and neutrophil engraftment.
Methods: Between January 2011 and Jury 2016, 76 patients received single-unit CBT at our institutions. We analyzed 59 patients for whom Tac was used for GVHD prophylaxis including Tac and Mycophenolate mofetil (MMF) combination (n=26) and Tac with an additional short Methotrexate (sMTX) (n=33). Sixteen patients who underwent second or third CBT and a patient for whom Tac was not used for GVHD prophylaxis were excluded. We also excluded a patient whose Tac concentration we didn't check more than two times a week. Tac was started at a dose of 0.02mg/kg/day by continuous i.v. infusion. Tac blood concentrations were monitored at least three times a week before engraftment, and dosages were adjusted to maintain serum levels about 10-20 ng/ml.
Results: Of the 59 patients, 48 patients achieved neutrophil recovery at a median of 22 (range 13-35) days. Two patients died before engraftment from severe PIR and active infection. Nine patients (18.6%) experienced graft failure. Patients who could maintain Tac level above 12ng/ml during the second week after CBT (Tac high group) had an incidence of graft failure of 4.8%, which was significantly lower than the 26.3% seen in the other patients (Tac low group) (p<0.01). Patients for whom Tac and MMF were used (MMF group) had an incidence of graft failure of 3.8%, which was significantly lower than the 36.4% seen in the other patients for whom Tac with an additional sMTX (MTX group) for GVHD prophylaxis (p<0.01). Combined of these factors, the patients of Tac low group and MTX group had had an incidence of graft failure 40.9%, which was significantly highest than the 5.4% seen in the other patient including Tac high group and MMF group even if the patient were included of Tac low group.

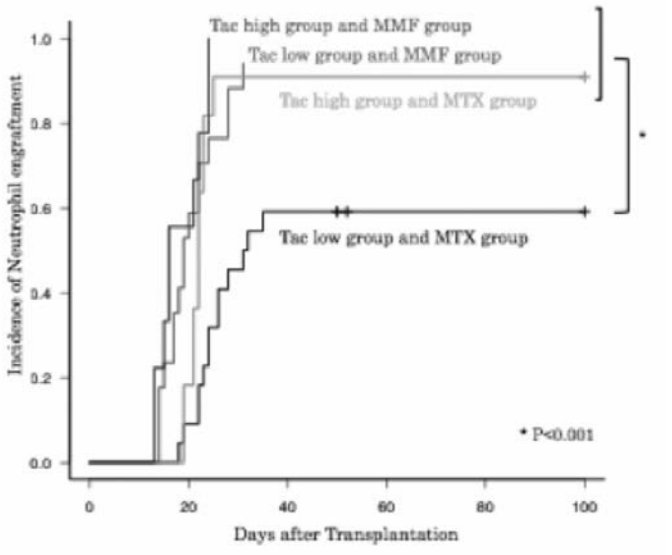

Figure 1.

Summary/Conclusions: Low levels of Tac blood concentration were significantly associated with the incidence of graft failure of the patient for whom Tac with an additional sMTX were used for GVHD prophylaxis. Before engraftment, frequent checks of the Tac blood concentration and maintaining the drug level should be considered for these patients.

THE EXPRESSION OF TOLL-LIKE RECEPTORS GENES IN PATIENTS WITH LYMPHOID MALIGNANCIES AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

J. Rybka[1,*], B. Jaźwiec[1], K. Wicherska-Pawłowska[1], R. Poręba[2], K. Kuliczkowski[1], T. Wróbel[1]
[1]Hematology, [2]Internal Medicine, Wroclaw Medical University, Wroclaw, Poland

Background: Peripheral blood stem cell transplantation (PBSCT) is one of the main strategies for the treatment of malignant hematological diseases. Toll like receptors (TLRs) are present on various immune cells including natural killer cells, monocytes, macrophages, T lymphocytes and B lymphocytes. Ten different TLRs have been evaluated in humans. TLRs play a central role in immune surveillance and in the initiation of the inflammatory response. The expression of TLRs genes and their association with outcome in patients treated with PBSCT remains unclear.
Aims: The objective of the current study was to investigate association between expression of TLRs genes and hematopoietic recovery and rate of infections in patients treated with PBSCT.

Methods: The evaluation of TLRs expression genes were performed in 40 patients who underwent PBSCT. The median age of patients was 54 years (range: 25-65 years). There were 15 patients with multiple myeloma (MM), 20 patients with non-Hodgkin lymphomas (nHLs) and 5 patients with Hodgkin lymphoma (HL). Peripheral blood samples were taken before megachemotherapy with autologous stem cell transplantation and at time of hematopoietic recovery in patients after PBSCT. Relative expression of Toll-like receptors was assessed by real-time PCR using inventoried TaqMan® Assays from Life Technologies/ThermoFisher. Beta glucoronidase (GUSB) served as endogenous control. Reaction was performed in 7500 Real Time PCR instrument (LifeTechnologies) using Gene Expression MasterMix (LifeTechnologies/ThermoFisher). Comparative C_T method (**) was used to compare expression among patients and with healthy controls. Statistical analysis was conducted using STATISTICA 12 software (StatSoft, Polska). For quantitative variables arithmetic means (X) and standard deviations (SD) of estimated parameters were calculated in the analysed groups. Distribution of variables was examined using tests of Lilliefors and W-Shapiro-Wilk. In cases of independent quantitative variables with the normal distribution the statistical analysis took advantage of t test for unlinked variables. In cases of variables manifesting distribution distinct than the normal one, for independent quantitative variables U test of Mann-Whitney was used. For dependent quantitative variables of the normal distribution, the t test for linked variables was applied. In cases of quantitative dependent variables with the distribution distinct from normal, the pair sequence test of Wilcoxon was applied. In order to define a relationships between the studied variables, correlation analysis was performed. Results at the level of p<0,05 were assumed to be of statistical significance.
Results: The mRNA expression of TLR2 and TLR9 was significant higher in patients after PBSCT than before PBSCT procedure (ΔCt TLR2 1,4209±1,0461 *vs* 1,7877±1,4974 and *Δ*Ct TLR9 117,853±141,0870 *vs* 289,788±271,98) (p<0,05). We observed that expression of TLR9 was significant higher in patients with bacterial and fungal infection after PBSCT in comparison to group without infection after PBSCT (ΔCt TLR9 117,853±141,087 *vs* 289,788±271,98) (p<0,05). Moreover we found significant positive correlation between expression of mRNA of TLR9 and neutrophil recovery after PBSCT (r=0,4075; p=0,023).
Summary/Conclusions: In conclusion our findings suggest that TLRs could be useful markers in outcome in patients treated with PBSCT.
This observation should be validated by larger study.

TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION: EXPANDED ACCESS PROGRAM FINAL DATA

S. Grupp[1], P. Richardson[2,*], A. Smith[3], N. Kernan[4], J. Antin[5], L. Lehmann[6], S. Giralt[7], W. Liang[8], R. Hume[8], W. Tappe[8], R. Soiffer[6]
[1]Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, [2]Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [3]Division of Pediatric Blood and Marrow Transplantation, University of Minnesota, Minneapolis, [4]Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, [5]Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, [6]Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [7]Memorial Sloan-Kettering Cancer Institute, New York, [8]Jazz Pharmaceuticals, Inc., Palo Alto, United States

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is an unpredictable, potentially life-threatening complication of hematopoietic stem cell transplantation (HSCT). VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal and/or pulmonary dysfunction post-HSCT in the United States. Prior to approval in the United States, defibrotide had been available via an expanded-access program.
Aims: To perform an exploratory *post hoc* analysis of final data from the expanded-access program on the impact on Day +100 survival of timing of initiation of defibrotide after diagnosis of VOD/SOS in HSCT patients.
Methods: In an expanded-access study, patients diagnosed with VOD/SOS (per Baltimore criteria, modified Seattle criteria or biopsy) with or without renal/pulmonary MOD after HSCT or chemotherapy received defibrotide 25mg/kg/d in 4 divided doses for a recommended ≥21 days after patients provided informed consent. For these exploratory analyses, D*ay +100* survival rates in HSCT patients were examined *post hoc* by time from VOD/SOS diagnosis to start of defibrotide for (1) all patients before/after days 1, 2, 3, 4, 7, and 14, using Fisher's exact test and (2) patients starting defibrotide on a particular day: 0, 1, 2, 3, 4, 5, 6, 7, 8–14, and ≥15, by Cochran-Armitage test for trend across days. Causes of treatment delay were not assessed.
Results: In the final dataset, timing of initiation date was available for 1000 HSCT patients (512 with MOD) who received ≥1 dose of defibrotide. In 31.0% of all HSCT patients, defibrotide was started the day of diagnosis; in 92.9%, by Day 7. In the population-wide analysis of initiation before/after days 1, 2, 3, 4, 7, and 14 post-diagnosis in both the overall group and MOD subgroup (**Figure 1**), earlier initiation was associated with significantly higher Day +100 survival rates for all days (*P*≤.001), except Day 14 (2.6% of patients started defibrotide after Day 14). The trend test for particular initiation days also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall HSCT group and MOD subgroup (*P*<.001). Adverse events (AEs) and serious AEs occurred in 70.8% and 53.4% of patients, respectively. Other than VOD/SOS and MOD, the most common AE was hypotension (11.7%) and most common serious AE was respiratory failure (7.3%).

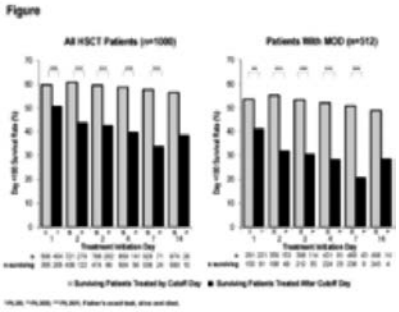

Figure 1.

Summary/Conclusions: In this exploratory analysis of final study data, earlier defibrotide initiation post-VOD/SOS diagnosis significantly improved Day +100 survival, confirmed by the Cochran-Armitage test (*P*<.001). No specific day provides a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.
